Dr. Clark began his reply by saying that if he had not been present, and Dr. Pollock's remarks had been reported to him he would have declared the report to have been incredible. Whilst paying a well-merited compliment to Dr. Pollock's clinical contributions to the history of phthisis he held that his unitarian views of its nature were not only untenable, but demonstrably erroneous. Dr. Clark would not meet mere assertion by assertion, but by argument and fact. Dr. Clark then proceeded to show that there was nothing in the diseased lung of his patient corresponding to any strict definition of tubercle. Here he noticed the loose illogical and vicious way in which this word was used, *and showed how necessary it was for the purposes of a sound definition to keep in view whilst framing it, not merely minute structure, form, seat, and methods of distribution, but the clinical phenomena grouped around the presence of the thing to be defined.* The fibroid deposit could not be called tubercular, and yet that was the main anatomical element of the cases which he described, and by which to avoid a hypothesis he had named them. If the cheesy masses of secondary lobular pneumonia were to be called tubercles then you would be confusing under one term products distinct and different from each other in origin, structure, seat, methods of distribution, and clinical characteristics; then language would cease to be useful to science, and progress in this direction would become hopeless. In true tubercular phthisis the primitive anatomical element was a grey granulation; in the disease described it was, in the first place, a fibroid or fibrogenous substance, and in the next a lobular cheesy pneumonia. The grey granulation was composed of nuclei or small cells, and a matrix sometimes fibrillated. The cheesy deposit was composed of large epithelial-like nucleated cells, or the products of their disintegration; the former sprung from the walls of blood vessels, the nuclei of textures, or the germs of colourless blood-cells were seated essentially in the depths of the textural elements; the latter sprung from the epithelial cells or their analogues on the alveolar walls, and were contained in the cavities of the alveoli. In tubercular phthisis the apex was commonly first affected, and the disease scarcely ever remained confined to one lung. In this disease the apex of the lung was commonly free, and in the majority of cases only one lung was affected. In tubercular phthisis the causes were most obscure. Here they were, most obviously, either an acute or chronic local inflammation, or a constitutional state clearly expressed. In tubercular phthisis the constitutional symptoms were profound; there were the quick pulse, the elevated temperature, the night sweats, and the great exhaustion. In fibroid phthisis constitutional suffering was often slight; the pulse slow; the temperature scarcely above that of health, and the disease indefinitely slow in its progress. But he would not multiply distinctions recognisable at the bed-side, even by tyros. It was impossible to have any intelligent and honest doubt of the existence of such cases as he had described, and of their peremptory claim to separate classification. He had no doubt that the time was nigh at hand when they would be as readily recognised as cases of pneumonic phthisis now are. For cases so distinct in their clinical and pathological relations distinctive designations must be found. To continue the use of the term tubercle in a comprehensive, as opposed to an exact sense, would be to perpetuate that confusion in which the whole subject of lung diseases is still needlessly involved, and to destroy the hope of acquiring any greater therapeutical power over them than we at present possess. To make any advance we must differentiate and define.

Literature.

DISEASES OF THE PROSTATE.

RATHER more than ten years ago there appeared a work on this subject which, while it put forth views at variance with those generally taught, was founded upon extended anatomical researches, and accordingly at once took an important place in medical literature. In 1860 the Jacksonian Prize of the Royal College of Surgeons of England was conferred on the author for his essay on "The Healthy and Morbid Anatomy of the Prostate Gland," and in a second edition of his former work he incorporated that essay. Another edition has now been called for; accordingly we have before us Sir Henry Thompson's last production.[1]

Having given a history of this handsome volume, it is unnecessary to attempt any lengthened criticism. The author's views are now well-known to surgeons, and his position at University College and the hospital, entitles his opinions to great weight, besides which, a work comprising the Jacksonian Prize Essay is not likely to be overlooked. There are thirteen fine lithographic plates, one of them delicately coloured, in illustration of the text. We welcome Sir Henry Thompson's new edition, and commend it to all interested in the subject.

STONE IN THE BLADDER.

A not uncommon complication of diseased prostate is stone in the bladder, and Sir H. Thompson has devoted sixty pages at the close of his work to this condition.

By this we are reminded of the last work on Stone in the Bladder, which has made its appearance, and which we may therefore as well notice in this connection.[2]

The purpose of this work is set forth in the title, and is more

1 The Diseases of the Prostate; their Pathology and Treatment. By Sir Henry Thompson, F.R.C.S., &c. London: J. Churchill and Sons. 1868.

2 Stone in the Bladder, with special reference to its Prevention, Early Symptoms, and Treatment by Lithotrity. By Walter J. Coulson, F.R.C.S. London: J. Churchill and Sons. 1868.

fully stated in the preface to be "to draw particular attention to the early symptoms of stone in the bladder, with a view to its safe and more easy treatment, and to certain conditions which predispose to the formation of stone with a view to prevention." This object is ably carried out, and Mr. Coulson, who has acquired a considerable reputation as a practical lithotritist, shows that he has taken a large view of the department of practice he has chosen, and has not only cultivated the manual dexterity required for the removal of stone by the lithotrite, but has studied the derangements of the system which give rise to calculus deposits, and the means, regiminal and medicinal, by which they may be obviated.

The book consists of three clinical lectures on the early symptoms of stone, its removal by lithotrity, and the after-treatment, and a chapter on prevention, which has not been thrown into the form of a lecture. The lecture on the early symptoms of stone is the most valuable of the three. These are shown to be much less marked than is commonly stated, though perfectly conclusive when carefully watched. Mr. Coulson considers them under the heads of hæmorrhage, pain, and irritation, and urges especial attention to the results of exercise, which, giving rise to mechanical injury of the mucous membrane of the bladder by the movement of the foreign body over its surface, furnishes the first indication of its presence. His observations on these points are worthy of careful study; attention to them will lead to the detection of stone at a time when it can be removed without danger and with little pain. The use of the microscope is advocated, and an interesting case is given, in which the diagnosis was made by means of this instrument. In the examination to ascertain the presence of stone, Mr. Coulson boldly discards the sound, except in the case of children, and employs only the lithotrite. With the sound, failures repeatedly occur in the ablest hands, and the lithotrite is not only surer, but occasions no more pain, while obviously it saves time, and diminishes the number of examinations required; or, to make a brief quotation, "it enables you to deal with the enemy at once." It is not necessary to say much as to the operation for lithotrity and the after-treatment. The directions for the introduction of the instrument and the exploration of the bladder are particularly clear, and we may mention that Mr. Coulson discountenances preliminary injections, and emphatically condemns the practice of bringing away fragments in the lithotrite, or of washing out the bladder after crushing for the purpose of removing *debris*. Impaction of fragments in the urethra appears to be unknown in Mr. Coulson's practice, and he attributes this accident, when it occurs, to laceration of the mucous membrane of the canal. The only case mentioned was one in which a stricture of the urethra had been split by the dilator to allow of the introduction of the lithotrite.

We have left ourselves little space for notice of the chapter on "Prevention." The causation of the various forms of calculus has been carefully gone into, and the treatment recommended is judicious. The author has been prompt to apply practically the excellent researches of Dr. Roberts on the solution of calculus, more particularly in endeavouring to prevent the recurrence of stone after its removal. The practical bent of the work has not, however, prevented some of the disputed points in urinary pathology from being discussed. The book will form a welcome addition to the literature of stone, covering, as it does, ground in a great measure new, and we recommend it to the attention of our readers.

THE VENEREAL DISEASES.

On this subject Mr. Bruce, of the Westminster Hospital, has prepared a little tract of notes[1] for students attending out-patients' practice, which will be found very useful to beginners, since it contains, properly classified, such notes as the pupils might be expected to take of the surgeon's clinical remarks. They are, however, not disjointed, but carefully arranged, so that a perusal of these few pages will give an ordinary student a bird's-eye view, so to speak, of the several manifestations of syphilis. We recommend Mr. Bruce's notes to first-year's men.

BANDAGING.

Now that the College of Surgeons requires candidates to exhibit their skill in bandaging, more attention will be devoted to it than has been the case for some years past. Mr. Berkeley Hill, who teaches the art at University College, has prepared a small manual[1] which will prove a boon to many a young student. In a small compass he will here find all he wants to know about every form of bandage and its uses, as well as directions for using all other kinds of surgical apparatus. The descriptions are clearly and concisely written, and 110 excellent engravings appeal to the eye in the most forcible manner, and can scarcely fail to impress the directions on the memory of the student.

1 An Epitome of the Venereal Diseases. By Alexander Bruce, M.S., (Lond.) London: H. K. Lewis.

1 The Essentials of Bandaging. By Berkeley Hill, F.R.C.S., M.B., &c. London: J. Walton.

TO OUR SUBSCRIBERS.

THOSE gentlemen who pay their Subscription in Advance, at the reduced rate of £1, 1s. 8d., will oblige by kindly forwarding the same for the present year, on or before 25th March inst. Subscribers who have not paid for the past year, are respectfully requested to remit the usual amount, £1, 2s. 6d., either by Cheque or Post-Office Order.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price* 5d. *Stamped* 6d.

By Post to Annual Subscribers, £1 2 6

,, *If paid in advance,* 1 1 8

*** Post-Office Orders and Cheques to be drawn in favour of CHARLES COOPER, 3, Lincoln-place, Dublin.

MACLACHLAN & STEWART, South Bridge, Edinburgh.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 18, 1868.

THE POOR-LAW BOARD AND DR. ROGERS.

THE Poor-law Board have called upon Dr. ROGERS, the Medical Officer of the Strand Union Workhouse, to resign his appointment, upon the ground that he has "placed himself in a position of antagonism to the Guardians, and has not evinced towards them that deference and courtesy which they are entitled to expect from their Officers." Dr. ROGERS denied this and other charges brought against him by the Guardians, and demanded an open inquiry—no reply was given to this application.

The question raised by the decision of the Board, and my attention has been directed to it by numerous correspondents, is whether the Poor-law Board have the power to dismiss a medical officer—appointed for life! upon an *ex parte* statement by the Guardians, that he is not sufficiently deferential towards them—such alleged want of deference not having interfered with the proper discharge of the duties of his office, as appears by the statement of the Poor-law Board, that "no complaint has been made to them in respect of the discharge of his strictly professional duties, and they do not doubt he has shown both zeal and ability in their performance." If the Poor-law Board have this power, their life appointments are a fiction, and no Medical Officer is safe who dares to speak, write, or publish anything contrary to the standard of deference and courtesy set up by the Guardians. Public opinion has declared itself in favour of Dr. ROGERS, with singular unanimity during his three months suspension. The ratepayers of St. Ann's, Soho, in which parish he resides, met in public-vestry meeting, with the clergyman of

the parish in the chair, to protest against the action of the Guardians, to express confidence in the Medical Officer, and to ask for a fair and open inquiry into the charges brought against him. A minority of the Guardians, comprising the most respectable and best-educated members, also addressed the Poor-law Board, scouting the malicious charges of the majority, and calling for the removal of Dr. ROGERS, suspension. This memorial remains unanswered to the present time. In answer to the vestry, the Board promised a fair hearing for Dr. ROGERS, a promise fulfilled by asking him what he had to say in reply to the "charges" which, by an industrious search of the minutes of the proceedings of twelve years, had been made to extend to more than 100 closely-written foolscap pages, half of them being copies of leading and other articles from the *Times*, the *Lancet*, and other journals, for which, without a tittle of evidence or proof, the Guardians held Dr. ROGERS responsible! Dr. ROGERS replied very briefly, reiterating his request for an inquiry, probably anticipating that he could not be condemned without one. But he was mistaken. Every circumstance points to the conclusion that he has been unfairly sacrificed to personal dislike. He had enemies among the Guardians—enemies at the Poor-law Board. Between these there appears to have been some sort of understanding, and upon most lame and impotent charges the Guardians suspended this able and faithful public servant, and the Poor-law Board have called for his resignation.

PHARMACY IN THE IRISH COLLEGE OF PHYSICIANS.

AT a recent Convocation of the President and Fellows of the King and Queen's College of Physicians in Ireland, a most important change was made as regards the declaration to be taken by Candidates for its license.

Hitherto no apothecary, English or Irish, could become a licentiate; and the sale of medicines under any circumstances was wholly forbidden to all ranks in the Dublin College.

According to the modern opinion of the Fellows this rule has been found to act injuriously; for not only were many English practitioners thus prevented from taking the license; but many Irish students were also thus precluded from entering the College of Physicians of their own country; and were obliged, by the force of circumstances, to resort to Edinburgh, or elsewhere, for what they could not get at home.

Under the new regulations, Licentiates of the Irish College of Physicians may compound and dispense, and charge for medicines for their own patients, and for none others. They may not keep open shop, or in anywise act as apothecaries—*i.e.*, as compounders (for sale) of the prescriptions of other practitioners. Apothecaries who may require their licenses as such for other purposes than keeping open shop may retain them, and, at the same time, become Licentiates of the King and Queen's College of Physicians in Ireland.

We have no doubt that many will avail themselves of this new piece of medical legislation which, in our view, will virtually cut away the ground lately taken up by the Irish Apothecaries' Company from under their feet; for no one who wants to be "a general practitioner" will hesitate for a moment between the "License" of the College of Physicians, and the "Certificate" of the Apothecaries Hall, of Dublin.

The following is the form of declaration to be signed by each candidate for the former license immediately previous to his admission as a Licentiate:—

"I hereby authorise the President and Fellows of the King and Queen's College of Physicians in Ireland to erase my name from the list of Licentiates; and I consent to surrender the Diploma received from the College, if I shall (after having obtained the License of said College) keep open shop for the sale of medicines."

It should be borne in mind that this new regulation is made wholly irrespective of the institution of the new order of "members" which the President and Fellows are generally understood to have under their consideration at present.

If carried into effect, this new order will virtually be no more than a revival of the order of "Candidates" which was abolished finally in 1792. The new, or revived, order, if instituted, will, *de facto*, replace that of the present Licentiates. "Members" will probably be subject to a higher class of examination than Licentiates; they will be wholly forbidden to practise pharmacy, or sell medicines, and from them alone will the Fellows be elected.

Notes on Current Topics.

Representation of the London University.

THE statement we made last week was quite correct, although a contemporary has hastily pronounced it "devoid of any foundation." The member of the British Medical Association who has duped the editor of that society's journal into asserting that the conservative graduates "have not, and do not propose to, put forward" Dr. Miller, would do well to confine his contradictions to matters within his sphere of observation.

Some of the foremost graduates have *re*-asserted their intention to make further efforts to bring forward Professor Miller, and others have expressed regret at having, as they now think, too hastily promised to support Mr. Lowe.

The gentleman, whose love of contradiction has added one more to the considerable stock of uncalled for and inaccurate denials of our contemporary, may be disposed to impugn this statement also. Nevertheless, we repeat that which the graduates in question have said to us.

Mortality in Hospitals.

LAST year, in 120 public institutions in London, there were 12,002 deaths, being one-sixth of the total metropolitan mortality. Thus 170 out of every 1000 deaths in 1867, took place in hospitals, and 3·9 of every 1000 of the population were in these hospitals at the time of their death. The mortality of the 36 general hospitals was 329, equal to 46·6 per 1000. That of 8 special hospitals was 929, equal to 13·2 per 1000; of 4 lying-in hospitals 82, or 1·1 per 1000; of 8 military and naval hospitals 177, or 2·5 per 1000. There were 100 equal to 1·4 in 3 hospitals or asylums for foreigners. In 19 lunatic asylums there were 357 deaths, being 5·4 per 1000 deaths. In the 46 London workhouses there were 6829 deaths or 96·7 out of every 1000 deaths in London.

If now we take in the deaths in hospitals and other institutions in the country, we find that in 853 public institutions in England and Wales containing 154,602 inmates there were 32,437 deaths. This is a mortality of 210 per 1000. In 690 workhouses, the mortality was 190 per 1000. In 106 hospitals it was 569. In 57 lunatic asylums 111.

Medical Society of London.

This, the oldest of all the London Medical Societies, held its ninety-fifth anniversary festival at the Freemason's Tavern on March 9th, Henry Smith, Esq., President of the Society, in the chair.

The Chairman was well supported by the Presidents of the Medico-Chirurgical and Obstetrical Societies, the Master of the Society of Apothecaries, and by Dr. Forbes Winslow, Dr. Hare, Mr. De Meric, Dr. Richardson (President elect), and other distinguished members of the profession.

In proposing the toast of the evening the Chairman congratulated the Fellows present on the flourishing condition in which he left their Society, and alluded to the distinguished men under whose auspices the society had first come into existence.

The health of the President was proposed in a very happy speech by Mr. De Meric, and that of the President Elect met with a most warm reception by the company when proposed to them by Dr. Forbes Winslow. Toasts in honour of the other learned Societies, and of the two Secretaries, Dr. Abbotts Smith and Mr. Mason, concluded the evening. It should be mentioned that before the dinner the usual oration was delivered before the Society and their guests by Mr. Teevan the orator for the year. This oration will appear forthwith in our columns.

The following officers for the coming year have been elected :—*President*—B. W. Richardson, M.D. *Vice-Presidents*—George Buchanan, M.D.; Victor De Méric, Esq.; Andrew Clark, M.D.; and John Gay, Esq. *Treasurer*—C. H. Rogers-Harrison, Esq. *Librarian*—Edward Head, M.D. *Secretaries in Ordinary*—Francis Mason, Esq.; and A. E. Sansom, M.D. *Secretary for Foreign Correspondence*—Julius Althaus, M.D. *Council*—J. W. Barnes, Esq.; John Birkett, Esq.; W. Cholmeley, M.D.; Charles Cogswell, M.D.; Alfred Cooper, Esq.; Walter J. Coulson, Esq.; R. W. Dunn, Esq.; Tilbury Fox, M.D.; S. Day-Goss, M.D.; Arthur Leared, M.D.; Morell Mackenzie, M.D.; Peter Marshall, Esq.; Henry Maudesley, M.D.; F. W. Pavy, M.D.; William Potts, Esq.; W. R. Rogers, M.D.; Abbotts Smith, M.D.; Henry Smith, Esq.; E. Symes, Thompson, M.D.; W. Spencer Watson, Esq. *Orator*—Duncan Gibb, M.D.

Gulstonian Lectures.

The lectures founded by Dr. Gulston, and delivered annually at the Royal College of Physicians of London, have been concluded for this year. As we have previously stated, Dr. John Harley was the lecturer for 1868. His first lecture was given on the 4th March, and in it he chiefly considered the physiological effects and therapeutical uses of conium. The result of his experiments seems to be that this drug depresses the functional activity of the corpora striata, as well as the reflex function of the spinal chord. The earliest symptoms are produced on the third nerve. Dr. Harley considers that conium exercises the same calmative influence on the nervous centres that is produced on the brain by opium. According to this view a patient completely under the influence of the drug may be looked upon as in a condition in which all motor function is in abeyance. The mode in which the poison is removed from the system also claimed attention.

Dr. Harley gave his second Gulstonian lecture on Friday, March 6th ; the subject treated of was the action of Atropia and Belladonna on the system. The experiments detailed went to prove that Belladonna acted as a powerful stimulant to the heart, and might be of service, by subcutaneous injection, in cases of prolonged syncope. Further, it was shown that this same medicine acted decidedly as a diuretic, and also as a quickener of the circulation through the lungs, and as a general oxydising agent.

The third and last of the Gulstonian Lectures was given before the College of Physicians on Wednesday the 11th. In this lecture, the properties of hyoscyamus were brought before the audience, and a variety of interesting experiments on men and animals were related. It appears that hyoscyamus, like belladonna, has a stimulating effect on the sympathetic nerve ; though not to the same extent as the last-named drug. The tincture and juice of hyoscyamus may be given to adults, and also to children, in doses of half-an-ounce or more without producing any more serious toxical effect than dryness of the mouth, and acceleration of the pulse. Hyoscyamus, when administered by the mouth, or by hypodermic injection, can, like belladonna, be very soon detected in the urine.

The lecturer, owing to press of time, was obliged to omit the account of many of his experiments on the conjoint action of opium and belladonna, and of morphia and atrophine, but several experiments were narrated which decidedly proved that belladonna greatly intensifies and prolongs the narcotic effect of opium when these two drugs are simultaneously introduced into the system.

In concluding, some useful remarks were made as to the causes of our ignorance respecting the action of remedies on the system, and physicians were exhorted to a more accurate study of practical therapeutics.

Close of Dr. Richardson's Lectures on Experimental and Practical Medicine.

The able course of lectures delivered this year by Dr. Richardson, and from time to time noticed in our columns, was concluded on the 10th inst. by a learned exposition of the lecturer's views on the nervous system, and the mode in which it is affected by anæsthetics. From various experiments, Dr. Richardson concludes that we have no reason to suppose that these agents enter into combination with the tissues. Nor does he regard the nervous system as the originator of force. He looks upon it rather as evincing its action in resistance to force from without. Vital force arises from the oxydation of carbon ; and, consequently, is eliminated at every point of the animal economy, and is conveyed to the nervous tissues by the circulating blood. Force is brought to bear upon the nervous system, which immediately offers resistance to it, or we may say that the system has at all times stored in it a certain amount of force, and that any addition to this disturbs the equilibrium, and produces an effort to re-establish the balance.

The lectures are now closed for the season. The next session does not commence until next October. It would, therefore, seem a suitable time to express what has so often been said during the course by those who have had the pleasure of attending, that Dr. Richardson may long continue to give these *seances*, which have become one of the most useful features of London medical society. Nor can we refrain from asking how it is that none of our colleges, or other learned bodies, have placed at his disposal their public rooms ? We should have thought that the Royal Colleges in Pall-Mall and Lincoln's-Inn would have competed for the honour of having these lectures delivered in their theatres. Men willing to lecture, a good audience,

and a private room—yet public halls almost constantly unoccupied! Is not this a disgrace to those who have the control of public halls? Dr. Richardson is one of the most distinguished Fellows of the Royal College of Physicians of London. Why do not his brother *Fellows* look to this?

Scotch Schools.

While the subject of middle-class schools is filling the papers, we cannot do better than extract the following description of a Scotch school, given by Mr. R. D. Fearon, one of the Assistant-Commissioners.

"The school is crowded with 60 or 100 boys and girls, all nearly of an age, seated in rows at desks or benches, but all placed in the order of merit, with their keen, thoughtful faces turned towards the master, watching his every look and every gesture, in the hope of winning a place in the class, and having goods news to bring home to their parents at tea time. The *dux* is seated at the head of the class, wearing perhaps a medal; the object of envy and yet of pride to all his fellows; fully conscious both of the glory and the insecurity of his position; and taught, by the experience of many falls, the danger of relaxing his efforts for one moment. In front of this eager animated throng stands the master, gaunt, muscular, and time-worn, poorly clad and plain in manner and speech, but with the dignity of a ruler in his gestures, and the fire of an enthusiast in his eye, never sitting down, but standing always in some commanding position before the class; full of movement, vigour, and energy; so thoroughly versed in his author or his subject, that he seldom requires to look at the text-book, which is open in his left hand, while in his right he holds the chalk or the pointer, ever ready to illustrate from map or black board, or, perhaps, flourishes the ancient "taws" with which in former days he used to reduce disorderly new-comers to discipline and order. The whole scene is one of vigorous action and masterly force."

The teachers in these schools are usually graduates of the Scottish Universities, and the whole report speaks of them in most favourable terms. Another point mentioned is the interest taken by parents in the progress of their children. The schools are, in fact, practically governed by the parents, who pay the cost of the education. The Commissioners may well approve so successful a system which is 300 years old, and which makes every parent, according to Mr. Fearon, as interested in the child's position in the class as he is himself.

Metropolitan Poor-law Medical Officers Association.

At a meeting of the Council of this Association, held on the 10th inst., Dr. Rogers tendered his resignation of the office of President. The Council, after expressing the surprise and regret with which they had learnt that the Poor-law Board had called upon Dr. Rogers to resign his appointment as Medical Officer of the Strand Union Workhouse, after stating that "no complaint has been made to them in respect of the discharge of his strictly professional duties; and they do not doubt that he has shown both zeal and ability in their performance," passed a vote of thanks to him for his past services, and, having declared their undiminished confidence in him, and their belief that it is still in his power to do good service in the cause of Poor-law Medical Reform, they unanimously requested him to continue to hold the office of President of the Council until the next quarterly general meeting of the Association, a course to which Dr. Rogers, after suitable acknowledgment of the kind feeling which dictated the proposition, cordially assented.

The Royal Commission on the Water Supply.

The report of the Royal Commission appointed to inquire into the metropolitan water supply is already decided upon, and will shortly be published. We are enabled to state that this report decisively rejects the various ambitious and expensive schemes that have been proposed, and recommends that the water supply should continue to be drawn from its present sources. The evidence adduced has satisfied the Commission of the sufficiency of the existing supply, as well as of the relative purity of the water.

The report will probably recommend a constant service at high pressure, and all the companies are, we believe, ready to adopt the recommendation.

Fibroid Phthisis.

An unusual degree of interest has been excited by the case of this disease reported to the Clinical Society of London by Dr. Andrew Clark, and of which a full abstract is given in the present number of The Medical Press and Circular.

Dr. Clark, it will be seen, looks upon fibroid as quite a distinct variety of phthisis, and has brought forward his views in a manner that could not fail to command attention. The subject is now before the Medical Society of London, and will consequently again be referred to in our columns. From what we hear we are disposed to think Dr. Clark's views will meet with general acceptance.

The Poor-law Board on the Supply of Medicines for the Sick Poor.

Owing to the pressure on our columns we are unable to insert the important correspondence between the Poor-law Board and the Council of the Metropolitan Poor-law Medical Officers' Association, arising out of a resolution passed at the quarterly meeting of the association. In our number for Feb. 26[1] we explained the bearings of the question, and, referring to section 69 of the Metropolitan Poor Act, 1867, which provides for the payment for medicines out of the Common Poor Fund, we stated that it had been assumed that as "the salary of a medical officer who has contracted to supply the medicines includes payment for the same, the repayment of the salary out of the Common Poor Fund is virtually repayment of the 'expenses incurred'" We regret to find that the Poor-law Board have taken this view of the case—strictly legal, we fear, but "entirely opposed to the spirit of the act." The promise, then, of Mr. Hardy, that "the drugs will be supplied by the unions," is a dead letter, and we can well understand the irritation of the medical officers at finding themselves still saddled with this charge. There appears to be a growing feeling in this large and respectable body of our profession that whatever benefits the poor may ultimately derive from the act, they themselves, or many of them, especially the workhouse medical officers, who have borne the heat and burden of the day, are likely to be thrust to the wall. So far, it is certain, they have gained nothing by the change which was effected by the passing of the act just a year ago. We trust that the question of the supply of medicines, and the formation of dispensaries, which appears to be progressing very slowly, if moving at all, will shortly be raised in the House of Commons. We are informed that not one dispensary has been opened as yet, and so far as we can ascertain, no dispensary committee

1 *Vide* Medical Press and Circular, page 185.

has been appointed. We cannot conclude our remarks on the correspondence before us without referring to the satisfactory opinion elicited from the Poor-law Board, that "the supplying of medicines by the guardians as a distinct proceeding on their part is an expedient course," and we hope, with the Council of the Association, that it will have due weight with the guardians, not in the metropolis only, but in all parts of the kingdom.

To-morrow (Thursday) a meeting is announced to be held at Masbro' in Yorkshire, to endeavour by united action on the part of the profession in that district to raise the present inadequate rate of payment made by the various sick clubs and societies for professional attendance during sickness. We heartily sympathise with the promoters of this object.

An indignation meeting was held last week in Southwark, caused by an alleged proposal to cart away the remains of the bodies in the Lock burial-ground. A resolution declared that such a proceeding would not only be a violation of the sanctity of the grave, but a constant cause of disease to the inhabitants of the locality. It was estimated that in 40 square yards 35,000 bodies have been interred. We trust they will not be disturbed.

Deaths from fever in the little village of Terling still occur; three more victims to the malady have succumbed during the past week, making 44 in the space of two or three months.

A sum of £150 has been recovered from a copper extracting company for damages to health and property caused by the noxious vapours emitted from the works.

Drs. Chambers, Druitt, and D. W. Moore are the three gentlemen selected in the last number of "Photographs of Eminent Medical Men." The likenesses are very good, and the letterpress is to the point.

It is said that several new candidates may be brought forward for the Principalship of Edinburgh University. Surely either Professor Christison or Sir James Simpson might satisfy the curators.

A bulky blue-book on Country Workhouses has appeared. It fully justifies our predictions as to the condition of these institutions. The Report on the Farnham Workhouse has likewise been issued, and consists of 160 pp.

Dr. Silver, on obtaining the Assistant-Physiciancy to Charing-cross Hospital, vacates the Chair of Botany. Applications for the latter may be sent in up to the end of the month.

Viscount Lifford will inquire after Easter the intentions of the Government as to extending the Contagious Diseases' Act, 1866.

A Poor-law Amendment Bill was read a first time in the House of Lords on Friday last.

Sir M. H. Beach is the new Parliamentary Secretary to the Poor-law Board.

SURGICAL SOCIETY OF IRELAND.

Friday, 14th February.

Mr. Porter, Vice-President of the College, in the Chair

(Continued from page 225.)

A CASE OF FRACTURED PATELLA, TREATED BY MALGAINE'S HOOKS.

By Mr. H. G. Croly.

Mr. President,—I feel that no apology is required in bringing under the notice of the Surgical Society the subject of fractures of the patella, when I find the following statement recorded in one of the standard works of the day:—

"The author believes from the results which he has seen, that fractured patella is one of the opprobria of English surgery."

I have had considerable experience in the treatment of the accident, and watched the result of the different methods of treatment recommended by authors, viz.:—Sir A. Cooper's plan, by a leathern strap buckled above the patella, with another strap passing under the foot; Wood's splint, which elevates the heel and has hooks behind to receive the figure of right bandage; Nélaton's plaster of Paris and strach bandage, strapping the fragments together with adhesive plaster, and elevation of the body to relax the muscles, &c., &c.

And though I have had several cases in which short ligamentous union took place, I was not satisfied with the result of the ordinary modes of treatment, which are exceedingly troublesome, painful, and tedious.

My special reasons for adopting the treatment of Malgaine in the case which I am about to detail were:—

1st. The great difficulty of bringing the upper fragment into anything like close contact with the lower one, &c.

2nd. The patient could not bear the appliances alluded to.

Mr. H——, aged 53 years, chief officer of Her Majesty's Revenue cruiser "Stag," was admitted into the City of Dublin Hospital, on the evening of the 27th of November, 1867, in an insensible state. The sailors who conveyed him to hospital gave the following account of the accident he met with. He was superintending the putting on of a false-keel on the "Stag" at the Ringsend dry-dock, about 3 o'clock in the afternoon; the ground was slippery from frost—his foot slipped, and he fell head foremost into the stone-bason, a height of about 20 feet; he was stunned from the fall, and his men lost no time in conveying him to the hospital.

It was my accident week, and Mr. Brown, the senior resident pupil, sent me notice of the case, and I visited the patient at once. I found him suffering from symptoms of concussion of the brain; there was a large contusion over the left brow and corresponding parietal region, and an angular projection of the left parietal bone caused by a fracture. On further examination it was discovered that he had a transverse fracture of his left patella, the fragments being sufficiently separated to allow my two first fingers in between them; the leg was bent; there was considerable effusion into the knee-joint, and the integument along the tibia was stripped off; *there was no abrasion over the knee.*

I first directed my attention to the concussion symptoms, and when reaction became established, I placed the left leg in the extended position, on a well padded M'Intyre's splint, and *raised the heel;* the limb was suspended in Luke's fracture cradle; and a cold lotion with pieces of ice were directed to be applied to the knee-joint.

The patient passed a restless night, and vomited several times; the fluid discharged from his stomach had a peculiar oily smell.

November 29th.—The swelling in the knee-joint having subsided, a figure of eight bandage was applied with moderate tightness, and the patient put into the *half-sitting posture.*

30th.—Patient became delirious, and commenced to remove the splint and bandages; he was ordered—

Lig. opii sedativi, ℥ij.
Tart. antimonii, gr. ij.
Mist. camph., ad ℥viij. ℿ.

Sumat cochl. amplum tertis horis.

After a couple of doses of this mixture he fell asleep, and had no return of the delirium.

December 1st.—Wood's splint for fractured patella with the figure of eight bandage, was applied with great care; the splint was kindly lent me by Mr. Porter.

2nd.—I visited the patient three times daily, and each time found the bandages loosened, and the fragment as wide apar

as ever. I tried strapping with plaster, and other modes of treatment, but he said he could not bear any of them. I explained to my patient, who is a most respectable and intelligent man, that he would, if he persisted in loosening the appliances, have an un-united fracture; he said he could not help it, and would not bear the strapping or bandaging.

I then told him of the "hooks," and confessed I had no experience in the use of them; he said he would allow me to put them on; accordingly, I got the hooks from London, and on the 4th of December, applied them in the following manner:—

I applied the "æther spray" to the integuments immediately above the patella over a small space, and having produced a sufficient degree of coldness, I felt for the upper margin of the patella, and put in the upper hooks (which were previously well oiled) into the quadriceps extensor tendon, so that their concavity embraced the superior border of the bone; the points penetrated about ¼ of an inch. I then applied the æther spray over the ligamentum patella, and applied the lower hooks, their concavity embracing the lower edge of the patella—the hooks held steadily by an assistant, with the screw I gently approximated them. The patient did not complain of pain at the time, and merely suffered a slight pricking sensation during the remainder of the day.

December 14th.—I tightened the hooks, and the fragments of the bone were in such perfect apposition that I could not feel any line of separation.

27th.—Hooks removed; limb still kept elevated on Wood's splint. A drop of pus escaped from each point where hooks were inserted. They were twenty-three days in.

January 7th.—Patient removed to lodgings near the city.

10th.—Starch bandage applied, and pasteboard instead of Wood's Splint.

February 12th.—Cast of knee and photograph taken, which I now exhibit to the society, also the drawing of the limb with the "hooks" in. I also exhibit the hooks and screw.

In bringing this case before the Society, I do not wish to under-rate the ordinary methods of treatment which I have on several occasions adopted most successfully in fractured patella. In this special case, my patient would not submit to the appliances which I tried with him. I shall next read for the Society the queries put to my patient, and his replies, which are in his own handwriting and signed by him.

Queries put to Mr. Harris.

Q.—How did you like the figure of 8 bandages—strapping of plaster, and other modes of treatment adopted before putting in the hooks?

A.—I could not bear any of them.

Q.—Did you suffer much pain or annoyance from putting in the hooks?

A.—Not any after a very short time, and never more than a slight pricking which ceased very soon.

Q.—Did the hooks, whilst left in, cause pain or annoyance?

A.—Never in the slightest degree.

Q.—What did you compare the hooks to when asked by different gentlemen who saw you with me?

A.—White wadding after the slight pricking of the first day.

Q.—Can you feel the separation between the fragments as you move your finger over the patella?

A.—A slight ridge exists, next to being imperceptible.

Q.—If you fractured your patella again, or the other one, what treatment would you wish for?

A.—The same (hooks).

In the *Medical Times and Gazette* (1864), sixteen cases of fracture of the patella are recorded by Mr. E. Pyle, House-Surgeon to the Middlesex Hospital; eight were treated by ***Malgaine's hooks***, and eight by other methods. Mr. Pyle says that the introduction of the hooks has, *in no case*, given rise to local inflammation or injury to the joint.

He directs attention especially to two cases.

M. T., who figures in *both* tables, when admitted, had fracture of *both* patellæ, with separation of the fragments to the extent of ¾ of an inch on the right side, and ½ an inch on the left. Hooks were applied to right patella, and the left leg was elevated on Earle's bed, and the broken bone kept in position by bandages. When discharged, *complete union* had taken place on the *right side*, but on the left there was still a considerable interval between the fragments.

In case of W. S., the point of interest is this:—Two years before he had fractured the other patella, and after treatment on the old principle for eight weeks, an interval of about an inch still remained between the fragments; this time he remained in the hospital less than eight weeks, and went out with a closely united patella.

SYNOPSIS OF SIXTEEN CASES OF FRACTURED PATELLA—EIGHT TREATED BY MALGAINE'S HOOKS, AND EIGHT BY OTHER METHODS.

No.	Name.	Age.	Sex.	Treatment.	Result.	No. of days in hospital.	Remarks.
1.	M. T.,	37,	F.	Malgaine's hooks applied 4th day.	Close union (not bony.)	78.	Hooks applied for 23 days.
2.	C. C.,	39,	F.	Do. 1½ hours.	Complete union.	42.	Do. for 35 days
3.	A. B.,	47,	F.	Do. 6th day.	Line of division can be felt, but no distinct interval.	41.	Do. for 33 days
4.	R. E.,	40,	M.	Do.	Not ascertained.	71.	
5.	P. N.,	35,	M.	Do. 23rd day.	Good union.	77.	Do. for 19 days
6.	H. D.,	40,	M.	Do. 7th day.	Do.	57.	Do. for 21 days
7.	W. S.,	37,	M.	Do. 2nd day.	Complete union.	41.	Do. for 27 days
8.	A. S.,	61,	F.	Do. 2nd day.	Do.	48.	Not ascertained.
9.	J. Y.,	25,	M.	Limb elevated upon an inclined plain.	Firm union.	50.	
10.	J. V.,	25,	M.	Do.	Interval of ⅛ of an inch between the fragments.	28.	
11.	M. T.,	37,	F.	Do.	Interval of slight extent remaining.	78.	
12.	M. C.,	60,	F.	Do.	Fracture united.	49.	
13.	C. E.,	45,	F.	Do.	Interval of ½ an inch remaining.	72.	When nearly well, fell down again and separated, uniting medium.
14.	E. T.,	47,	F.	Do.	Ligamentous union, half an inch interval remaining.	56.	
15.	C. N.,	23,	M.	Do. back splint.	*Not united.*	49.	
16.	E. W.,	47,	F.	Do.	Fracture ununited.	91.	

In the *British Medical Journal*, February 8th, 1868, a case of fractured patella, treated by Malgaine's hooks is recorded.

The patient was admitted into the Middlesex Hospital, under the care of Mr. Campbell de Morgan. The fracture occurred on the 11th of June.

On 4th day, hooks were applied.

On 16th of July, no inconvenience or pains from the hooks.

July 11th.—Hooks were removed.

Very good union had taken place (1 month.)

N. Nélaton used several times the instrument of M. Malgaine, in order to keep the fragments of the fractured patella together, and says "he never found any of those inconveniences to result from its use, which have been so singularly exaggerated."

The following case of fracture of both patellæ was admitted into the City of Dublin Hospital in 1859, and noted by me as House-Surgeon. The case occurred in Mr. Tufnell's accident week.

Ellen Morgan, aged 37 years, a nurse, residing at Pembroke-place, was carried to the hospital on Sunday evening, March 6th, 1859.

She states she was carrying a child down a dark stair an hour and a half before admission; when she reached the third step from the bottom, her feet slipped; she threw herself forcibly backwards to save the child, and, in so doing, felt her *right* knee crack. She then fell against the bannisters.

On examination I detected a transverse fracture of the right patella, and was able to put two fingers between the fragments; there was no contusion of the joint. The left knee-joint was much swollen and ecchymosed, so much so, that no accurate diagnosis could be made at the time. Subsequently, when all effusion had subsided, a transverse fracture was discovered.

Case in which the left patella was fractured by muscular action four times. I exhibit a cast and photograph.

James M'Court, aged 21 years, was admitted into the City of Dublin Hospital on the 28th of August, 1863. He gave the following account of the accident:—He was upon a wall, and dropped down, having had a hold of the top of the wall

with one hand, when he reached the ground he slipped, and was falling forwards, when he made a violent effort to save himself by throwing his body backwards—he felt his knee-cap crack ; he walked home, a distance of four miles, assisted by a boy.

On admission, the fracture was found to be transverse, there was no contusion of the knee, and he says his knee did not touch the ground.

Fracture united by short ligament, and he left the hospital contrary to my wish. He went to work, and had good use of the limb. On the 13th of October following, he slipped on an orange-peel, and was admitted again into the hospital with a fracture or separation of the fragments at same situation, caused by slipping on an orange-peel, and the violent effort to save himself from falling. It united in five weeks, and though cautioned as before, he left the hospital, and was admitted on the 9th of December following, with rupture of the ligamentum nerves, caused by an effort to save himself from falling downstairs. It united again, and on the 3rd of February, 1864, he was knocked off the channel, when he felt the knee yield, and was ashamed to come back.

The cast and picture show a separation of three inches between the fragments, with an intervening ligamentous substance. He wears a splint at the side of the knee, and walks as if he had a stiff joint.

CASE OF FRACTURE OF THE RIGHT PATELLA FROM MUSCULAR ACTION.

Michael Rourke, aged 35 years, a baker, residing at Cabinteely, slipped going down an inclined plane on May 28th, 1866, and was about to fall, when he threw his body forcibly backwards and fractured his right patella transversely ; he was conveyed to the City of Dublin Hospital on July 29th, sixty-six days after the accident, and admitted under my care. I treated him by elevation of heel, and figure of 8 bandages, and strips of plaster.

He left hospital on 29th July. He was unable to go to business for nearly a year after accident.

To-day, February 13, 1868, he called on me, and can move his knee and bend it well; there is a short ligamentous union.

Mr. Adams, in his valuable essay on Abdominal Conditions of the Knee-Joint, in Cyclopædia of Anatomy and Physiology, relates the following remarkable case which occurred many years ago in the Richmond Hospital, under the care of the late distinguished surgeon Todd:—

A muscular man, a lamplighter in this city, was on the top of his ladder when it slipped from the lamp-post, and he fell with it to the ground, making at the moment vain, but violent efforts to save himself. The whole muscular system, according to his own account, seemed to be suddenly thrown into energetic and involuntary effort to resist the fall; when he was lifted up he was unable to stand. Mr. Todd having examined him, found both olecranæ, and both patellæ broken transversely.

Holmes, in his system of surgery, says—"The frequency of fractures of the patella in the transverse direction seems to have led English surgeons to the belief that the majority of fractures of this bone are of muscular origin. This is contrary to the experience of foreign surgeons, who attribute the greatest number of these fractures to direct violence: thus, of nine cases related by Boyer, five were caused by falls on the knee, which accident likewise produced eleven of the nineteen fractures observed by Malgaine ; while of fourteen which came under the observation of Hamilton, thirteen were the result of direct blows on the knee, and one only was due to muscular action."

M. Malgaine has shown that the separation is not, after a time, occasioned solely by the ascent of the upper fragment, but that it depends partly upon the descent of the lower—in consequence of the gradual contraction of which the ligament patella undergoes. In one case he found this ligament shortened more than inch, and it was not more than half the length of the ligament on the uninjured side. The retraction of the ligament had, in this instance, produced a greater effect even than the contraction of the muscles. But, besides being separated from each other, the fractured portion of bone undergo a displacement of another kind: they are tilted forwards so that the anterior edges of the fractured surfaces are made widely separated than the posterior. This obliquity does not affect both pieces to the same extent, but is much more marked in the lower than in the upper. M. Malgaine believes this is principally due to the slow contraction of the igamentum patellæ, the under fibres of which being longer than the others, undergo a greater amount of shortening, and draw downwards the anterior surface of the lower fragment to which they adhere. *The movement is increased by any apparatus which aims at the approximation of the fragments by means of the constriction above and below the patella.*

The reason why transverse fractures of the patella do not commonly unite by callus, is *not* owing to the want of power in this bone to produce an osseous connecting substance; for, as Lanly has several times noticed, if the fragments are kept in perfect contact by means of a suitable apparatus, their bony reunion becomes so complete, that scarcely any vestige of the injury can be afterwards traced—*vertical fractures of patella readily unite by bone.*

The CHAIRMAN observed that the paper which they had just heard from Mr. Croly was a most practical one, and he would be happy to hear it discussed.

Mr. TYRRELL said he had seen several cases of fractured patella, and so far as his experience went, Mr. Croly's observation that all the ordinary methods of treatment were attended with injury was not correct. He had published a number of cases in THE MEDICAL PRESS AND CIRCULAR, where the patients suffered no permanent injury. One remarkable case was that of an old woman, who could not be kept in a recumbent position. She was obliged to sit up in bed, and to be moved about, and she suffered no injury, the union was an excellent one, although there was some small distance between the parts. As to some surgeons thinking that the injury was so often caused by muscular action, he could only say that that was not his experience. In some cases, which had come under his notice there was so much ecchymosis that it was some time before any retentive means could be put on. It would be more satisfactory if Mr. Croly's case was seen at a longer period after the treatment had ceased. The cast showed that there was an evident deformity ; there was a slight amount of depression in the centre which would go far to prove that it was not bony union ; and in the next place, it would be remarkable if perfect osseous union could take place in seventeen days. Generally, it was necessary to keep the limb under treatment for a much longer period, and considering that the patella was a bone not well suited for osseous union, the case was a remarkable one. In a translation of Dupytren, it was stated that he had been very successful in obtaining bony union by a simple provision—namely, putting on two calico bandages, and bringing the fractured patella together. It was stated that Dupytren's practice was exceptional, but Dupytren said himself that the cause of his success was the length of time he kept the bandage on. It was a curious fact that Malgaine's hooks were not employed at present in Paris, so that they were given up by the French surgeons. He did not know whether Mr. Croly had seen the gentleman lately or not.

Mr. CROLY—The cast was taken yesterday, and I saw the gentleman when it was being taken.

Mr. TYRRELL observed that ligamentous union might occur, and there might apparently be an osseous union, but this might give way when the limb was used ; so that, for some time, the surgeon should be cautious in saying that there was osseous union.

Dr. BENSON said he happened to be present when the gentleman was undergoing examination yesterday, and he was astonished at the closeness of the union.

Mr. STOKES could confirm the practical value of Malgaine's hooks. This was the second time he had seen a case of fractured patella under treatment by this method. The other instance occurred in a hospital in an obscure town in Germany. He thought that this operation had been brought into ill-deserved repute, not only in Paris, where it originated, but in other celebrated surgical schools. He had heard a two-fold objection urged against this mode of treatment by clinical teachers. One was that it produced tetanus. Another was the great pain necessarily attendant when the clamps of Malgaine were applied. As to the first of these objections—the liability to the supervention of tetanus—he was not aware of any case having been recorded in which tetanus occurred after the application of Malgaine's clamps ; and if it had it was just as likely to have been induced by the injury—the fracture of the patella—as by the application of the clamps. As to the second objection, the great pain which attended the operation, he could only speak from his observation of two cases. He visited the patient in the City of Dublin Hospital fourteen or fifteen days after the clamps had been applied. The patient was lying perfectly free from all uneasiness and pain, no evidence of any local or constitutional disturbance.

In answer to Professor HARGRAVE,

Mr. CROLY said that the patient came to hospital on Nov. 27th, and the hooks were applied on Dec. 10th.

Professor HARGRAVE—And then in seventeen days after that, union took place. If they examined the cast they would see that the union evidently was not osseous. Mr. Croly stated that the treatment of fracture of the patella had been the opprobrium of British surgery. That he (Professor Hargrave) denied. He thought the figure of eight bandage was one of the worst bandages they could apply to the fractured patella. He had had considerable practice in these cases, and he did not see the necessity for adopting the hooks. If the case was treated properly, proper bandages, &c., applied, the fractured patella would unite without difficulty. These hooks had been given up in Paris, so that they must have been found to be useless. As surgeons, their object should be to teach their pupils to apply the simplest and most efficient remedies.

Mr. CROLY, in reply, said with regard to Mr. Tyrrell's objection as to muscular action causing the fracture, he had merely stated the opinion of English and French surgeons. He had seen a great many fractures of the patella, and in some instances he thought it had been caused by muscular action. He was of opinion, that when a man slipped backwards he fractured the patella first, and fell afterwards. He knew an instance of a man having fractured the patella who never hit the ground at all. He did not say a word about bony union, and unless he got the patella and macerated it he could not say that bony union had taken place. He merely said that of all the cases he had seen under his own care, none had been more successful than this one. He had no idea of decrying other methods, and only brought the case forward to show that a man who could not be treated by other methods had been cured by the application of Malgaine's hooks. As to tetanus, he had seen it follow from the crack of a whip, and therefore he did not attach much weight to the objection.

REPORT TO THE REGISTRAR-GENERAL ON THE METROPOLITAN WATER SUPPLY.

By Dr. E. FRANKLAND, F.R.S.

ANALYSIS OF THE METROPOLITAN WATERS FOR FEBRUARY, 1868.

1 Companies.	2 Date and Place of Collection.	3 Temperature in centigrade degrees.	4 Total solid impurity in 100,000 parts.	5 Organic Carbon.	6 Organic Nitrogen.	7 Nitrogen as Nitrates and Nitrites.	8 Ammonia.	9 Total Combined Nitrogen.	10 Previous Sewage Contamination (Estimated.)	11 Total Hardness.

Worthing	NOVEMBER. Worthing.		36·7	·162	·000	·426	·000	·426	3940	23·8

For the purpose of comparison, I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by waters supplied to the towns of Lancaster, Manchester, Leicester, Preston, and Worthing, when submitted to the same analytical processes. The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 4th February, at the Horse Guards cab-rank had a temperature of 7·2 C.; 100,000 lbs. of it contained 30·8 lbs. of solid impurity; the organic matter constituting a portion of this impurity contained ·326 lb. of carbon and ·052 lb. nitrogen. This solid impurity also contained ·340 lb. of nitrogen in the form of nitrates and nitrites, besides ·002 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·394 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 3100 lbs. of average filtered London sewage.

By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the Company, this sewage contamination had been converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 18·8 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The waters delivered by the New River, East London, and Kent Companies were clear and transparent, but with the exception of the West Middlesex, all the companies drawing their supply from the Thames were delivering imperfectly-filtered water on the day when the samples were taken. The Lambeth Company's water was so muddy that brightly-illuminated objects could not be seen through a stratum of it twelve inches deep. The Chelsea Com-

1 In the last month's report, through a clerical error, the total combined nitrogen in the Chelsea Company's water was given as ·339 instead of ·398.

pany's water was but little better in this respect, and the supply of both companies was, on this ground alone, entirely unfit for domestic use. The water delivered by the Southwark and Grand Junction Companies was only slightly turbid. The organic matter contained in all the samples of water, except those of the West Middlesex and Southwark Companies, was highly nitrogenised, and therefore probably of animal origin to a considerable extent. The condition of the Kent Company's water, delivered at the Deptford Railway Station on the 7th instant, presented remarkable peculiarities. It contained the very large amount of 59·2 parts of solid impurity in 100,000 parts of the water, 42 parts being the maximum, and 39·3 the mean amount observed in this company's water during the year 1867. Of the above 59·2 parts, no less than 14·7 were common salt, the occurrence of which in such quantity is difficult to account for, except on the supposition that the Company's wells have some connection either with the sea or the brackish reaches of the Thames. The previous sewage contamination was also higher than that observed on any previous occasion.

For the first time since February, 1867, the East London Company's water exceeds that of the New River Company in previous sewage contamination.

ROYAL COLLEGE OF CHEMISTRY,
London, Feb. 29, 1868.

Correspondence.

DR. LETHEBY'S LECTURE ON FOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to Mr. R. Griffith's (Ch. M.) futile attempts to trace inconsistency in Dr. Letheby's admirable Lectures on Food, I would remark that although I am well aware how useless it is to try to reason with people who commence their arguments by espousing preconceived ideas, and dogmatically taking for granted what they ought first to prove, yet I would ask what Mr. Griffith really intends to convey in his most obscure letter, in your issue of February 26. When he states that "everything which is not food, except air and water, is a foreign body or poison to the animal economy, and therefore injurious to it," am I right in assuming that he means that every medicine which is not assimilated is not only inert but injurious to the animal economy? Should I have, by a happy hit, interpreted his meaning aright, I wish he would for the sake of our Profession furnish proofs, and not simple assertions, of this newly discovered theory.—Believe me, dear sir, yours very truly, A. M., M.D.

A SUBSCRIBER'S PROTEST.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a subscriber of many years' standing to your excellent journal, I beg to protest against the continued occupation of your space, to the extent of several columns, by the unpaid for advertisements of the so-called "Ladies' Medical College," in the form of letters signed by one of the officials of that anomalous institution—a Dr. Edmunds. I also protest against the insertion of long letters filled with offensive vituperation of a most eminent member of our profession, and varied only by an extremely uninteresting record of Dr. Edmund's personal squabbles with his professional brethren in behalf of the institution with which he is connected.

I have no personal acquaintance with any of the gentlemen engaged in this dispute, but if the facts be as stated, there can, I think, be no doubt that Dr. Eastlake has been very badly treated, and that no medical man, with a vestige of self-respect, could have acted otherwise than he has done.—I have the honour to be, sir, your obedient servant,

A DUBLIN SUBSCRIBER.

THE captain and several of the crew of Her Majesty's frigate *Arethusa* have been attacked with small-pox and scarlatina, but are now doing well. The ship is being disinfected.

HOSPITAL APPOINTMENTS IN DUBLIN.

THE appointment of Mr. Butcher, as Auxiliary-surgeon to Sir Patrick Dun's Hospital, to which we adverted last week, was necessarily followed, under the recent regulation of the Board of Trinity College and the College of Physicians against plurality, by the resignation of that gentleman's connection with Mercer's Hospital. In strict rule the vacation of the surgeon's connection with Mercer's Hospital ought to have preceded his election to Sir Patrick Dun's; but in this instance that course was not adopted owing to circumstances which as they have been already made public elsewhere, we feel ourselves called upon to detail.

We understand that on the rumour of Mr. Butcher's retirement from Mercer's Hospital, a difference of opinion arose as to the propriety of appointing to the vacancy, it being held by a majority of the surgical staff that that department was already sufficiently provided for, and that if the vacancy were to be filled at all, the financial arguments hitherto adopted were objectionable. Now, the special Act of Parliament under which the Hospital is regulated declares that the physicians and surgeons, so long as they shall serve without fee or reward, may *add* to their number by the vote of a majority of two-thirds. If Mr. Butcher had vacated his seat previous to the election of the incoming surgeon, the Board would have been divided three to two, or a majority of less than two-thirds, and the appointment could not have been made. Mr. Butcher, however, having retained his position and his vote, a *fifth* surgeon was duly elected, and the number at once reduced to four by his resignation.

By this election Mr. B. F. M'Dowell, Lecturer in Botany in the Ledwich School of Medicine, becomes surgeon to the Hospital. Mr. M'Dowell is a Bachelor of Medicine of the University and a Licentiate of the Royal College of Surgeons, and the King's and Queen's College of Physicians, and an influential private teacher in Botany, Materia Medica and Pharmacy.

We understand also that the selection of Mr. Wharton as Surgical Examiner in the University of Dublin has not yet been officially declared, although we believe our anticipation of it will prove to be accurate.

Medical News.

THE LATE SIR D. BREWSTER.—It has been decided to erect a statue to Sir David in Edinburgh. Last week a meeting in the Royal Society's Rooms was called for the purpose of considering the propriety of commemorating his services in the cause of science. Sir David Baxter, of Kilmaron, was called to the chair; and among others present were Lord Neaves, Sir David Dundas, Sir James Y. Simpson, Sir George Harvey, Professor Playfair, Professor Balfour, Professor Tait, Dr. Alexander Wood, Dr. Andrew Wood, Dr. Keith Johnston, Mr. Milne Horne, of Wedderburn, Mr. Bryce, architect, Mr. Francis Brown Douglas, &c. It was unanimously resolved, on the motion of Lord Neaves, seconded by Dr. Andrew Wood, that a monument, taking the form of a statue, to Sir David Brewster, should be erected in some public and conspicuous part of Edinburgh. A committee was appointed to carry out the resolution. Sir James Y. Simpson has received the following letter from the Prime Minister:—"10, Downing-street, Whitehall, March 5, 1868. Dear Sir James,—I have much gratification in informing you that Her Majesty has been graciously pleased to grant a pension of £200 per annum to the widow of Sir David Brewster, in recognition of his eminent services to science. I have the honour to remain, dear Sir James, yours faithfully, B. DISRAELI. Sir James Simpson, M.D."

ESTIMATE FOR GREENWICH HOSPITAL AND SCHOOL.—The estimate for Greenwich Hospital and School for the year 1868-69 has just been published. The total for the year is £127,608, against £128,635 for the year 1867-68, and the net decrease is, therefore, £1027. Comparing the two years it appears that a considerable saving was effected in "salaries and allowances, household, and infirmary,"—"repairs and maintenance of buildings"—"provisions, clothing, bedding, and stores." The gross decrease was counterbalanced by an increase of £6620 in "pensions to seamen," and other smaller increases.

VITAL STATISTICS OF PARIS.—M. Haussman has just issued the returns for 1867, which shows that the total mortality of the City of Paris during the year was 43,415. The

THE CANTOR LECTURES AT THE SOCIETY OF ARTS.

Dr. LETHEBY'S THIRD LECTURE ON FOOD.

CONSTRUCTION OF DIETARIES: PREPARATION AND CULINARY TREATMENT OF FOODS.

The construction of dietaries involves a variety of considerations, as—1st. The determination of the real wants of the body under different circumstances of age, sex, constitution, labour and climate; 2nd. A proper selection of food, as regards quality, nutritive power, appetizing property, digestibility and price; 3rd. The association of foods in such wise as not to offend the appetite or burden the digestive powers; 4th. A right treatment of them by cooking, &c., so as to render them most useful to the system; and 5th. A just distribution of the daily diet in appropriate meals.

As regards the first question—namely, the determination of the actual dietetical wants of the body—it may be answered from two sets of facts, as those which pertain to the minimum quantities of food capable of being used without loss of health or bodily vigour, and those which relate to the amounts of carbon and nitrogen exhaled from the body during different conditions of life.

In a general way it may be said that a healthy vigorous man consumes from 700 to 800 lbs. of solid food (dry) in a year. This amounts to about 2 lbs. of dry, solid matter daily; and the quantity of water (free and combined) is about 5½ lbs. daily.

Pursuing the inquiry a little farther, we find that a man cannot live on a punishment prison diet of 1 lb. of bread a-day, with water; for in three days he will lose about 3 lbs. in weight, and will show signs of commencing starvation. This diet contains 1·3 oz. of nitrogenous matter and 8·42 of carbonaceous (= 1995 grains of carbon, and 90 of nitrogen). Even the poor needle-women of London can only just exist in a state of feeble vitality, with an average diet of 1½ lbs. of bread a-day, with about 1 oz. of dripping. This contains nearly 2 oz. of nitrogenous matter, and 14·85 of carbonaceous, calculated as starch (= 3272 grains of carbon and 135 of nitrogen). And in military prisons where as much as 3·8 oz. of nitrogenous food, and 22·2 oz. of carbonaceous (= 6925 grains of carbon, and 256 of nitrogen), are supplied daily to prisoners for short terms of confinement, they frequently lose weight and give evidence of decay; so that for longer periods of imprisonment it is found necessary to increase the diet to 4·7 oz. of plastic matter, and 27·8 of respiratory (=8647 grains of carbon, and 317 of nitrogen): in fact, according to Dr. Christison, the men confined in the prison at Perth cannot even do the work of pumping the water for the prison on a daily diet of 6 oz. of plastic matter, and 25 of respiratory (= 7239 grains of carbon, and 405 of nitrogen).

Again, Dr. Edward Smith found in his inquiries into the dietaries of adult male operatives of Lancashire and Cheshire, during the cotton famine, and also into those of the low-fed operatives of England, that the daily amount of food only barely sufficient for existence must contain 2·84 oz. of nitrogenous matter, and 19·25 of carbonaceous (= 4300 grains of carbon and 200 of nitrogen). These are contained in 2 lbs. 3 oz. of bread, which is regarded as a famine diet. The farm labourers of England consume daily an average of 3·18 oz. of plastic matter, and 26·01 of respiratory. In Scotland, Wales, and Ireland, the amounts are somewhat larger, as will be apparent from this diagram.

AVERAGE DAILY DIET OF FARM-LABOURERS IN THE UNITED KINGDOM.

	Dry Nitrogenous matter.		Dry Carbonaceous matter.		Carbon.		Nitrogen.
	oz.		oz.		grs.		grs.
In England ...	3·18	...	26·01	=	5810	...	228
In Wales ...	4·12	...	31·22	=	6901	...	290
In Scotland ...	4·76	...	31·34	=	6297	...	335
In Ireland ...	4·94	...	28·73	=	6195	...	348
Average of all	4·25	...	29·07	=	6477	...	300

These are the results of inquiries into the dietaries of many hundreds of families, the results being computed as for adults; but it is very probable, as Dr. Smith remarks, that the nourishment obtained by the labourer himself is somewhat above the average. This, in fact, is confirmed by the more extensive investigations of Dr. Lyon Playfair, who concludes, from a large series of observations, that the following may be regarded as the average proportions of

the several constituents of food in the daily dietary of an adult man under different circumstances of existence.

Daily Diets for	Flesh former.	Fat.	Starch and Sugar.	Nitrogenous.	Carbonaceous calculated as Starch.
	oz.	oz.	oz.	oz.	oz.
Subsistence only	2·0	0·5	12·0 =	2·0	13·2
Quietude ...	2·5	1·0	42·0 =	2·5	14·4
Moderate exercise	4·2	1·8	18·7 =	4·2	22·0
Active labour	5·5	2·5	20·0 =	5·5	26·0
Hard work ...	6·5	2·5	20·0 =	6·5	26·0

These conclusions accord pretty well with the determinations of Pettenkofer and Voit, who say that an adult requires daily, when at work, 5·22 oz. of nitrogenous matter, and 22·38 of carbonaceous (calculated as starch). Taking, therefore, the mean of all these investigations, it may be said that a man requires daily the following amounts of carbonaceous and nitrogenous matter for idleness, for ordinary labour, and for active labour :—

	Nitrogenous.	Carbonaceous.	Carbon.	Nitrogen.
	oz.	oz.	grs.	grs.
Idleness ...	2·67 ...	16·83 =	3856 ...	187
Ordinary labour	4·56 ...	24·48 =	5757 ...	319
Active labour	5·81 ...	24·31 =	5837 ...	400

By pursuing the second method of inquiry, and ascertaining the wants of the body from the amounts of carbon and nitrogen exhaled and secreted, it is found that the proportion of carbon evolved as carbonic acid from the lungs of a man in health varies from 6 oz. to 13½ oz. daily, the difference being dependent on temperature, exercise, &c. Dr. Edward Smith says that it amounts

to 7·85 oz. daily while the body is quiet ;
to 9·11 do. with moderate exercise ;
to 12·19 do. with considerable labour.

And he considers that a healthy man of average weight (150 lbs.) emits 8·57 oz. of carbon from his lungs daily. This added to the quantity discharged from the skin and bowels is not less than 9·6 oz. daily (= 4200 grains) or just 28 grains per lb. of the man's weight. During light labour, he says it ranges from 9·6 oz. to 10·5, and during hard work from 12·5 to 14 oz.

The amount of nitrogen excreted as urea, &c., in the urine is also subject to great variation according to the diet and exercise. Dr. Parkes found in his experiments on two soldiers, that with an ordinary diet, and no exercise, it amounted to 2·03 grains per lb. weight of the body (= 304 grains per 150 lbs); and that with a non-nitrogenous diet and no exercise, it was 0·95 gr. per lb. weight (= 142 grains per 150 lbs.); and with the same diet and active exercise it was 2·42 grains per lb. weight (= 364 grs. per 150 lbs.)

Professor Fick and Wislicenus observed that the nitrogen secreted during an ordinary diet and no exercise, was at the rate of 1·53 grains per lb. weight (= 230 grains per 150 lbs.); and that it fell to a little less than one grain per lb. weight with a non-nitrogenous diet during the labour of ascending the Foulhorn.

The researches of the Rev. Dr. Haughton, of Dublin, have led him to conclude that an average sized man performing routine work secretes 187 grains of nitrogen as urea daily (= 1·25 grains per lb. weight) ; and Dr. Edward Smith has estimated it at from 0·93 to 1·4 grains per lb. weight—a fair average being 1·15 (= 173 grains per 150 lbs.).

The more extensive inquiries of Playfair, Ranke, Beigel, Moos, Vogel, and others, give a daily average of 171 grains of nitrogen as urea for a healthy man at rest, and 252 grains for ordinary labour.

It may, therefore, be safely concluded that with an ordinary diet, an average sized man excretes daily as urea 175 grains of nitrogen ; and during labour of a moderate description it amounts to about 250 grains. Adding to these the proportions of nitrogen excreted in other forms in the urine, and the quantities passed from the bowels, the total amounts are probably about 190 grains while at rest, and 300 grains when at routine work ; the difference, perhaps, being more dependant on the food than on the tissues of the body.

It thus appears that the proportions of carbon and nitrogen excreted correspond very closely with those contained in the diets, which experience has proved to be necessary for man's sustenance; for when the results are put into a tabular form they stand thus :—

DAILY REQUIREMENTS OF THE BODY.

		Nitrogenous Food. oz.	Carbonaceous Food. oz.	Carbon. grs.	Nitrogen. grs.
During idleness as determined	By Dietaries	2·67	16·83 =	3856	187
	By Excretions	2·78	18·47 =	4200	190
	Average	2·72	17·65 =	4028	188
Routine work as determined	By Dietaries	4·56	24·48 =	5757	319
	By Excretions	4·39	19·80 =	4813	300
	Average	4·48	22·14 =	5285	310

The first of these averages is represented by 2 lbs. 2 oz. of bread, and the second by about 3½ lbs. It appears also that the relation of the nitrogenous to the carbonaceous constituents of food should be about as 1 to 5½ or 6. These in fact are the proportions which Messrs. Lawes and Gilbert found to be best suited for fattening pigs. In milk, the proportions are as 1 to 3·6 (the butter being calculated as starch) ; and no doubt these are the right proportions for the dietaries of children. Again, it will be observed, that the relations of the nitrogen to carbon is nearly as 1 to 19 ; whereas in milk it is about as 1 to 11. Referring to table No. 4 (p. 85) it will be noticed that the proportions in bread are as 1 to 22, and in meat as 1 to 13, showing that the former requires the addition of plastic matter, and the latter of respiratory.

In preparing dietaries, however, it will perhaps be best to take a rather liberal view of the question, and, therefore, I shall adopt the conclusions of Dr. Edward Smith—that even in periods of idleness a man's daily food should contain not less than 4300 grains of carbon, with 200 of nitrogen ; and a woman's at least 3900 grains of carbon with 180 of nitrogen—these being the proportions which, in his opinion, are necessary to avert starvation diseases ; and they are represented in the case of a man's diet by 19·25 oz. of carbonaceous food, with 2·84 of nitrogenous. The diagram before you exhibits the amounts of different articles of diet capable of furnishing this quantity of nitrogenous matter, and it also shows the proportions of carbonaceous matter (calculated as starch) associated with it.

AMOUNTS OF FOOD YIELDING 200 GRAINS OF NITROGEN OR 2·84 OZ. OF PLASTIC MATTER NECESSARY FOR A MAN'S DAILY DIET.

Description of Food.		Carbonaceous matter in it.	Carbon in it.	
	oz.	oz.	grs.	
Skim-cheese ...	8·8	5·57	1290	Carbon deficient
White fish ...	24·6	5·99	1384	
Skim-milk ...	94·1	8·96	2059	
Peas	12·6	9·33	2141	
New milk ...	91·4	9·40	2160	
Lean meat ...	18·3	11·36	2629	
Oatmeal ...	22·9	17·54	4000	
Wheat-flour ...	26·7	19·28	4433	Carbon in excess
Baker's bread ...	35·6	19·28	4433	
Indian meal ...	26·0	19·83	4554	
Rye-meal ...	36·4	26·40	6046	
Barley-meal ...	45·7	34·02	7800	
Rice	45·7	34·02	7800	
Bacon ...	32·6	38·04	8714	

So that, while the first seven of these substances are deficient of carbonaceous matter (19·25 oz. being required), the last seven contain it in excess. It is, therefore, not difficult to construct a dietary from the several tables which I have placed before you; but perhaps it would interest you to know exactly what are the actual dietaries in use

among different classes of persons; and first I will direct your attention to what Dr. Edward Smith found to be the average weekly dietaries of the low-fed operatives of England, Wales, Scotland, and Ireland.

WEEKLY DIETARIES OF LOW-FED OPERATIVES.—CALCULATED AS ADULTS (E. SMITH).

Class of Labourer.	Bread Stuffs.	Potatoes.	Sugars	Fats.	Meat.	Milk.	Cheese.	Tea.	Containing		Cost.
									Carbon.	Nitrogen.

Shoemakers, Coventry	179·8	56·0	10·0	5·8	15·8	18·0	3·3	0·8	31700	1332	2 7¾
Farm-labourer, England	196·0	96·0	7·4	5·5	16·0	32·0	5·5	0·5	40673	1594	3 0
Do. do. Wales	224·0	138·7	7.5	5·9	10·0	85·0	9 8	0·5	48354	2031	3 5¼
Do. do. Scotland	204·0	204·0	5·8	4·0	10·3	124·8	2·5	0·7	48980	2348	3 3¾
Do. do. Ireland	326·4	92·0	4·8	1·3	4·5	135·0	—	0·3	43366	2434	1 9¾
Mean of all	184·2	78·1	8·0	4·5	10·7	42·9	3·1	0·6	34167	1500	2 7¾
Average per day	26·3	11·1	1·4	0·6	1·5	6·1	0·4	0·1	4881	214	0 4½

You will see from this table that the poor needlewomen of London are the worst fed of all the operatives in the three kingdoms, for they subsist on a weekly allowance of 102·52 oz. of carbonaceous food, with 13·49 oz. nitrogenous (= 14·65 oz. carbonaceous, with 1·93 oz. nitrogenous daily), while the farm-labourers of Ireland are, as regards the real nutritive value of their food, the best-fed of the lower operative classes. But it will also be noticed that the cost of the weekly dietary of the Irish labourer is only 1s. 9¾d. per week, while that of the needlewoman is 2s. 7d.—the latter feeding chiefly on bread, bacon and tea, which are expensive foods, while the former consumes potatoes, milk, and Indian meal—foods which yield more nutriment for their money value than the more expensive foods of the English, Welsh, and Scotch labourers.

And now we will contrast the dietaries of the poorer classes of operatives with those of better-fed persons, as soldiers, sailors, navigators, &c.; and for this purpose I shall avail myself of the accurate returns obtained and published by Dr. Lyon Playfair.

DAILY DIETARIES OF WELL-FED OPERATIVES (PLAYFAIR).

Do. of low-fed Operatives...	3·04	0·64	21·18	22·78	3·04	4881	214

In all these cases the carbonaceous matters of the food are estimated as starch; and I may state that the soldiers' dietary, when at peace, is calculated from the rations of the English, French, Prussian, and Austrian service; and when at war, it is derived from the actual dietaries of European and American soldiers during recent wars.

It would be interesting, if time permitted, to compare these dietaries with the dietaries of hospitals, prisons, workhouses, and lunatic asylums; for we should then perceive not merely how greatly they vary in their nutritive value, but also how little attention is paid to the principles which ought to guide our public authorities in the construction of public dietaries. In the prisons of England, Scotland, and Ireland, the several dietaries for short terms of imprisonment, as well as for longer periods, and for hard labour, vary respectively to so great an extent as to furnish an inducement for the commission of crime in certain districts rather than in others, because of the richness of the prison rations; and in all cases the dietaries of prisons are so largely in excess of those of the union, that in times of distress they offer encouragement for misdemeanour, in order that the prison may be reached in preference to the workhouse; in short, while the day's ration of an unfortunate inmate of a union contains only about 17 oz. of dry nutritious matter, that of a destitute debtor contains 19·4 oz., and that of a convict 22 oz.; moreover, a prisoner confined for more than a month without hard labour in the jails of England, Scotland, and Ireland, would have 18·8 oz., 22·4, and 23·9 of dry nutriment respectively; the average rations for hard work containing about 21·7 oz., 31·5, and 25·6 in the prisons of the three countries.

Dr. Edward Smith has drawn attention to the serious want of uniformity in the dietaries of the unions of his district, and has urged the workhouse authorities to improve them. He has also submitted to the Privy Council tables of dietaries, which are well suited to meet the requirements of the system at the lowest money cost. Here are a few of them, which may perhaps prove useful to those who are engaged in the benevolent work of supplying food to the poor in times of distress; and you will perceive that at various sums, from about two shillings to three shillings a-week per adult, very substantial rations may be provided.—(See Table next page.)

The dietaries of women should be about 1-10th less than those of men in the case of in-door operatives, but they ought to be from 1-3rd to 1-4th less than the larger dietaries of men engaged in out-door labour.

As regards the dietaries of children it may be stated generally that the chief part of their food should be milk. Up to the age of nine or ten months it should be, if possible,

DIETARIES TO FURNISH AS NEARLY AS POSSIBLE 30,100 GRAINS OF CARBON, AND 1400 GRAINS OF NITROGEN PER MAN WEEKLY—WOMEN TAKE ONE-TENTH LESS (SMITH).

the milk of woman, which is richer in sugar than cow's milk, and much less rich in caseine; failing this, however, asses milk is a good substitute, as it contains nearly the same amount of sugar and caseine as human milk. MM. O. Henri and Chevalier have given these as the properties of the several constituents in 100 parts of the milk of different animals.

Cow's milk, therefore, diluted with about one-third its bulk of water, and sweetened with sugar, may be given to children; and up to nine or ten months no other food should be administered, for infants have not the power of digesting farinaceous or fibrinous substances. A child may take from two to three pints of milk thus diluted daily. After ten months, and to about twenty months, farinaceous matters may be mixed in gradually increasing quantities with the milk; and they should be well cooked by first baking them, and then thoroughly dissolving them by boiling. After this age, and up to the third year, the quantity of well-cooked farinaceous matters may be still further increased, and given as puddings with a little egg. Bread and butter may also be eaten, and towards the end of the time the child will digest well-boiled potatoe, with a little gravy of meat. From the third to the fifth year a little meat may also be given, and at the end of the ninth year it may partake of the usual food of the family; but all along it should make use of a large proportion of milk in the various forms of bread and milk, or milk puddings with eggs. About the tenth year a child will require about half as much food as a woman; and at the fourteenth year it will eat quite as much as a woman; in fact, the proportions of food required by the child is much greater per pound weight of the body than that of adults, because it has to form its tissues, and build up its several structures. Dr. Edward Smith calculates that the proportions of carbon and nitrogen in the daily food at different ages should be about as follows:—

DAILY PROPORTIONS OF CARBON AND NITROGEN IN THE FOOD AT DIFFERENT AGES, PER LB. WEIGHT OF THE BODY.

	Carbon. grs.	Nitrogen. grs.
In infancy	69	6·78
At ten years of age ...	48	2·81
At sixteen do. do. ...	30	2·16
At adult life ...	23	1·04
In middle age ...	25	1·13

So that for its weight the infant requires three times as much carbonaceous food, and six times as much nitrogenous as an adult.

The construction of dietaries for particular purposes, as for training, for developing muscular tissue, for producing fat, or for reducing it, is beyond the scope of these lectures; but it may generally be said that, as in training, the object is to form muscular tissue, to give it great endurance of action, and at the same time to reduce the weight of the body, it is accomplished by the use of nitrogenous food with but little fat or farinaceous matter, and as little fluid as possible—so that muscular tissue may take the place of fat and water; and by constant exercise the endurance and strength of the muscular tissue is increased. King, in training, is said to have taken for his breakfast two lean mutton-chops, somewhat under-done, with dry toast or stale bread, and a single cup of tea without sugar; for dinner 1 lb. or 1¼ lb. of beef or mutton, with toast or stale bread, and very little potatoes or other vegetable, and half a-pint of old ale, or a glass or two of sherry; for tea a single cup of unsweetened tea, with an egg and some dry toast; and for supper half a-pint of oatmeal porridge or half a-pint of old ale. The effect of this is to produce only a short-lived state of effectiveness, for carried a little beyond the appointed time, it leads to disease; and even after the trial, there is often, as in the case of Heenan, terrible prostration of the system, and a necessity for returning immediately to an ordinary diet.

Foremost among the foods for developing fatty tissue are fats, as fat of meat, butter, cream, &c.; next to these are farinaceous matters, as arrow-root, starches, and the various meals; and after these are sugar, alcohol, &c.; so that in an attempt to reduce the bulk of the body, all of them, but especially the first, should be but sparingly used. Conversely, however, the use of fatty and farinaceous foods has a tendency to produce fat, and so also with fermented liquids, as beer and porter—the last having a high character for its capabilities of forming milk, when drank by nursing women.—(To be continued.)

LECTURES ON VENEREAL DISEASES
DELIVERED IN
DR. STEEVENS' HOSPITAL.

LECTURE III.

By ROBERT McDONNELL, M.D., F.R.S.,
ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

(Continued from page 242.)

8TH. Successive relays of symptoms. This aspect of syphilis in which its tendency to return again and again is shown, has been misnamed relapse. It is, in truth, no evidence of relapse, but evidence of a natural tendency in the complaint not to die out at once, but to die out gradually, making itself visible in a succession of outbreaks at intervals of some weeks, and each often slighter than that which has gone before.

If, however, you find this line of progress is departed from—if the second and third crops of eruption follow each other quickly, and each is worse than that which has succeeded it—we have in this the most important of all indications for a specific treatment. "If," says Diday, "a roseolar eruption at first has been succeeded by a squamous eruption for the second crop, the prognosis is altogether different from what it would be if the crop succeeding the first consisted of lesions diminishing in severity. But besides the peculiarity of each outburst, we should never lose sight of the degree of rapidity with which they follow each other."

Let us compare these two cases.

	Number of days of 2nd incubation, *i.e.*, from the appearance of the Chancre to the appearance of 1st crop of eruption.	Number of days from date of appearance of 1st crop to appearance of 2nd.	Do. from appearance of 2nd to appearance of 3rd.	Do. from 3rd to 4th crop.	Do. from 4th to appearance of 5th crop.
Case of mild Syphilis....	40 days.	38 days.	134 days.	—	—
Case of severe Syphilis....	60 days.	28 days.	20 days.	32 days.	44 days.

In the mild case, but few successive crops after longer intervals; in the severe one, more numerous crops separated by shorter intervals.

You may ask me then why I have not adopted a specific treatment in the case of Michael K——, at present in No. 2 Ward. He is 18 years of age, and was admitted on the 19th of August last, having on him a roseolar eruption. He was discharged, seemingly well, on September 23.

He was readmitted on October 21, having a papular eruption on his arms, shoulders, face, and thighs.

This got better, but on November 30, a fresh outburst took place, in which pustules were mingled with the papulæ.

Erysipelas of the head came on, and, as a consequence, the glands of the neck suppurated.

A fourth slight eruption occurred at the commencement of the present month. No mercurials have been given in this case, yet you see the patient is now every day getting better.

I tell you, gentlemen, that in this instance I have departed from my own principles, and I have done so in order to impress upon you the more the power which syphilis has of working its own cure. This is a case in which I have gone beyond my usual practice, in order to impress upon you this most important of all the truths connected with syphilis, and I have erred as regards the principles which I wish to teach you—at least, I have violated the general principles which I wish to lay down in having adopted throughout in this man's case a non-specific treatment.

Upon what grounds in the case of Matthew M—— is mercury administered, while to all appearance the disease does not appear to bear upon him so heavily as upon the other? I answer. This man is 58 years of age; he has escaped from syphilitic infection for 58 years; at that age the reparative powers are feeble as compared with younger subjects.

Men over 50 have lost that elasticity and vigour of constitution which is so important in the struggle with a morbid poison. You all know that youth is the time to get typhus over you—typhus hits very heavily after the age of 50—so does syphilis. His age alone determines a mercurial treatment in his case.

J. —— has a chancre, now healed, an indolent bubo, a roseolar eruption on the chest and abdomen, with severe rheumatic pains and slight mucous tubercles in the fauces. He is twenty-two years of age. Watch his case; you will find that he will need no specific treatment to effect his cure.

Michael B—— had scrofulous abscess in his neck in childhood, the traces of which he still bears on his neck. Having contracted syphilis he was exposed to circumstances in the highest degree likely to make it severe. He is a cab-driver on night service, he has been much exposed to the inclemency of the weather and frequent wettings; he admits that he had recourse to the consolation of spirituous drink as frequently as he could get it. Such circumstances are most likely to change a mild syphilis into one of a malignant character. Such has been his case. The syphilitic eruption was papular, abscesses formed in the neck, axilla, and at the ankle; iritis supervened. Mercurial treatment was indicated in this case.

Without going the full length of the anti-mercurialist school, I admit that in my judgment the great question as regards syphilis is, how far can we judiciously dispense with a mercurial treatment. Von Baerensprung's view coincides with that which I have arrived at; according to him, "Mercury does not cure syphilis, mercurialism causes the symptoms of the disease to disappear for a time. As long as the mercurial action lasts, syphilis remains in a latent state, reappearing afterwards by so much the more terrible in proportion as the mercurial intoxication has weakened the constitution of the patient," nevertheless, there are cases in which you must deal with the symptoms.

The cases, such as that which I have detailed at the beginning of this lecture, in which I have seen direct proof of the power of syphilis to get well without mercurial treatment, are those on which my own convictions are based. There are other facts, however, to which I may point; and I fancy some may be surprised to find proofs drawn from the writings of those who are themselves strong and decided mercurialists. Moliere's "Bourgeois Gentilhomme" was surprised to find that he had been talking prose all his life without knowing it. I am not certain that the mercurialist will be as well pleased to be told that he has been practising anti-mercurialism without knowing it. In fact, patients cured by the calomel vapour-bath are cured on anti-mercurial treatment. I am now satisfied that calomel used in this way has no specific effect. Calomel is not absorbed by the skin.

When I was a student I frequently ordered, under the direction of the late Dr. Hutton, calomel ointment for the treatment of psoriasis and lepra, not syphilitic. Those who were acquainted with the practice of this eminent surgeon, will remember that he frequently prescribed an ointment consisting of one drachm of calomel to an ounce of lard, to be freely rubbed over the surface of the body in such cases. I was struck by the fact that this mercurial preparation, so active when given internally, never mercuralized when rubbed over the skin in the form of ointment. I have known pounds of it to be used—rubbed in in ounces daily over the entire body—but I never knew a case to be salivated by it. Later, when turning my attention more to the subject which at present occupies us, I found that mercurialization did not follow even the very frequent use of the calomel vapour-bath—provided the patient did not let his head into the vapour and inhale the

?

sublimated calomel. When a patient leaves the calomel vapour-bath, if we scrape the surface and examine what has been there deposited in the microscope, we find the sublimated calomel in crystals—a form ill adapted for cutaneous absorption.

Doubting that it ever was absorbed in this way, I made some experimental observations. Some ounces of finely lavigated calomel were tied in a muslin bag. Every day, after coming out of an ordinary warm bath, the patients were dusted over with the calomel in the bag, from the waist down. I have, myself, rubbed ounces of calomel over the legs, abdomen, and scrotum, leaving the patient as white as a miller with it, but I have never found it salivate.

There is a simple method by which we can test in many cases the general action of mercury on the human organism—if we apply to the skin a small disc of gold (or anything gilt) as a patient becomes salivated it becomes *silvered*. I generally use one of the discs of an old gold shirt-stud stuck to the skin in the axilla with a piece of sticking-plaster. I have not found this test give evidence of general mercurial absorption, when calomel has been freely rubbed over the lower half of the body day after day. In fact, so convinced am I that under ordinary circumstances the cutaneous absorption of calomel does not take place, that although I have no love for it, yet, so far as regards fear of mercurialisation, I should not mind spending a month up to my neck in a sack of calomel. How is it then that the calomel bath has been found to do so much good?

It is, gentlemen, simply the vapour-bath acting beneficially on a malady which tends to get well of itself. Monsieur Jourdain has been speaking prose without knowing it.

I have now, gentlemen, endeavoured to point out to you some of the general indications which will enable you to determine whether you have a severe or a mild case of syphilis to deal with. The details of treatment you must learn at the bed-side.

You must not suppose, however, that when I say that the majority of cases of syphilis may be cured without the use of mercurials that I would have you leave such cases to themselves—by no means.

If a syphilitic patient smokes and drinks beer half the day, and plays cards and drinks punch half the night, or if, like our patient B——, the cab-driver, he is exposed night after night to wet and cold, and at the same time under whiskey-punch treatment, his case will become aggravated—his disease will pass from the mild to the severe form. You must lay down strict rules for living. You must, by simple means, keep the skin, kidneys, and bowels in action. I am told, "Your cases at the Mountjoy Prison were not like ordinary cases in the outer world. You could there enforce a hygienic discipline such as cannot be enforced in general." There is, no doubt, some truth in that, yet the curing of soldiers and prisoners by an enforced hygiene proves the great power of such treatment; and it is at least your duty to put this strongly before your patient.

If he will not submit to the discipline and instructions necessary for his cure in the one way, he must be prepared to undergo a treatment which will leave him a more or less enfeebled man for the rest of his life. Let his blood be on his own head.

Original Communications.

ON THE TREATMENT OF DISEASES OF THE SKIN.

By J. L. MILTON,

SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

CHAPTER II.—SQUAMÆ.

A. Lepra and Psoriasis—Definition.—An eruption of ham or salmon-coloured, slightly elevated papules, often looking at first like scattered drops of tallow grease, gradually becoming covered with thin, extremely dry, hard white scales, often coalescing into large irregularly shaped patches, peculiarly prone to appear, among other parts, on the knees and elbows; the scales becoming very light and silvery in some cases; not accompanied or followed by vesication, ulceration, or forming of pustules. Often a good deal of itching.

The sooner the word psoriasis is entirely omitted the better. It is really in the ordinary sense of the word, a form of lepra, displaying the same features and requiring the same treatment. I have, therefore, left it out altogether, and all that is said of lepra must be understood as applying to psoriasis also. Mr. Wilson, indeed, has proposed that the latter word should be used only for the dry, scaly stage of eczema, and that lepra should be known in future as alphos. I would suggest the entire expulsion of psoriasis, and should it be considered indispensable to use a Greek word for the dry state of eczema, I would suggest that psora be retained, being classic-Greek, and a very significant word.

Treatment.—If I were to rely exclusively on my own experience, I should say that time was lost, at the beginning at any rate, in trying any remedy for this complaint except arsenic, which should be commenced at once and taken in the largest doses the patient can bear. Should the arsenic disagree with the patient the dose may be lessened, or when the stomach is considerably out of order, it may even be given up for a day or two, and a saline prescribed instead, till the arsenic can be borne again, when it is to be at once resumed. It is given in the same doses and in the same way as for lichen and prurigo, but cases may occur in which it is as well to leave the beaten path, and try what amount of this potent mineral can be supported, as nothing short of the maximum amount will do good. Dr. Moriarty[1], in a case of inveterate lepra, gave ten minim doses of Fowler's solution four times a-day, and effected a complete cure, though the disease had lasted seven years and four months.

Suppose, however, it should be absolutely necessary to suspend the arsenic, are there any other reliable remedies? I know, by experience at least, of none that can be depended upon as a substitute for the arsenic, but there are several which will improve the health, and when arsenic has done its work, will often contribute to the disappearance of the eruption.

Among these steel holds a foremost place. It may be given both when the patient is taking arsenic, and when he has suspended it; but I would always advise that the two medicines should be prescribed separately, and independently of each other. Another useful auxiliary is the iodide of potassium in tincture of bark, accompanied by small doses of biniodide of mercury; or the surgeon may prescribe the nitro-muriatic acid in doses of fifteen or twenty minims, with the same quantity of compound tincture of cinnamon, and a drachm of tincture of gentian or calumba, two or three times a-day, a little before meals. From a course of cod-liver oil, too, I have often seen the best effects; in fact, I may say, that as a rule I give it in every refractory case of lepra, and that means the great majority of cases. In my hands De Jongh's oil has so far answered the best, and most patients can take it better than the pale oil. Generally only moderate doses, such as a teaspoonful or two, two or three times a-day, are generally sufficient. The best vehicle that I know of for the oil, is ginger-wine. Finally, I may add the galium aparine, a remedy which has been highly praised by Dr. Winn. At one time, in consequence of Dr. Winn's recommendation, I gave it pretty freely, and though I never cured undoubted lepra with it, yet, certainly, the eruption, and the health too improved under its use. Mr. Hunt seems to have given it a very fair trial, he procured the fresh herb itself from the fields near Kentish Town, and had it boiled down. Considerable benefit resulted from the use of it, but in every case this was only temporary. The inspissated

1 *Mdical Times and Gazette*, 1863, Vol. 1, p. 101.

juice, when properly prepared, is so costly that it can never be generally employed among the middle and lower classes.

There are some other remedies of reputed efficiency, but of which I have no experience. Among these are dulcamara, considered by Bateman as one of the most effectual medicines in all varieties of lepra; the great dock of India or asclepias gigantea, discovered by Playfair, formerly said to be possessed of such extraordinary power over the leprosy of the East, but now considered by many writers to be totally inert; the great marsh wort of India or hydrocotyle asiatica, also said by Bazin[1] to be powerless in cutaneous disorders, though considered extremely efficacious by some writers. Psoriasis is also said to have been cured by the use of the Turkish bath, of mineral waters, such as those of Harrogate, Purton Spa, and Barèges, and to have disappeared under the influence of vaccination, tincture of cantharides, sulphur, frictions, with juniper tar, with which Bazin says he has cured cases which had resisted every kind of treatment, (toutes les medications), copaiba, and sundry other remedies.

With regard to the statements respecting the curative power of these remedies I have little to say, as I have not tried them. I assume they are made in good faith, but I confess I am sceptical as to the curative power of the medicines themselves. It is to be remembered that the complaint will sometimes disappear under the influence of medicines which impure the health, and I am strongly disposed to believe that with attention to the general condition, arsenic will cure any case likely to yield to simple means, and cure it too more quickly and certainly; indeed, it is not improbable that some of the cures said to have been effected by the use of chalybeate waters were really due to the arsenic said to have been discovered in some of these solutions.[2]

Mr. Wilson gives arsenic for this disease in the form of Fowler's solution, and the ferro arsenical mixture.[3] He begins with two or three minims of the solution, and gradually increases the quantity to five minims, beyond which he does not often go. Mr. Wilson considers the white precipitate ointment very useful in lepra.

Mr. Startin treats lepra with a great variety of remedies, relying little upon arsenic alone, but there are so many ingredients in his prescriptions that an analysis of them is difficult. Chalybeates, both internally and in baths, arseniate of mercury dissolved in hydrochloric acid, iodide of mercury and opium, persulphate of iron and hydriodic acid, arseniate of potass with aperients, such as sulphate of magnesia, constitute the chief items of his treatment. When inflammation runs high, he gives sulphate and carbonate of magnesia with colchicum and Plummer's pill; for indigestion and clay-coloured stools, liquor potassæ and mercury.

Dr. Willshire in bad lepra gives decoction of elm bark, as a vehicle for some more active remedy such as bichloride of mercury. He also gives lemon-juice and tincture of cantharides. Dr. Willshire keeps his patients on a very strict diet, forbidding meat and limiting them to milk and bread, watercresses, &c. In Mr. Hunt's practice also, an exclusively vegetable diet has sometimes been found necessary. Bazin in arthritic psoriasis, gives a tablespoonful of alkaline syrup, and some alkaline mineral water at meals. He also applies the huile de cade, and orders weak alkaline lotions with a little glycerine every three or four days; also alkaline and vapour baths. For the herpetic form, M. Bazin prescribes frictions with oil of juniper-tar, and internally arseniate of iron and soap-wort in the form of a plasm. In the young adult, when the urine shows a continued low specific gravity, and a less than normal amount of urea, Mr. Nayler finds a combination of steel and arsenic very useful. Dr. Hillier gives liquor arsenicalis in large doses, beginning with five or six minims three times a-day, and increasing the quantity to ten or twelve minims. He expresses himself as so well satisfied with the result that he has not given cantharides a fair trial. He speaks favourably of the action of the empyreumatic oils, such as the tar of the betula alba, after the scales have been removed by water dressing, and considers that the diet should not be too rich or azotised.

Hebra breaks loose in one overwhelming anathema against the drugs recommended for lepra; root and leaf, bark and flower, acids and alkalies, sulphurets and muriates, old messes and new-fangled compounds, are all included under one common ban. The anthrocokali, which was to cure every disease of the skin, is just as powerless as the Chinese ethiop's mineral, or the stibium with which of old the Greek ladies painted their eyebrows. I wish some person in this part of the world would be as plain spoken. There are positively hundreds of remedies recommended for diseases of the skin, of which it is very doubtful whether one was ever subjected to such a test as it ought to have gone through before being admitted to the privilege of having a word said in its favour; yet once it gains a footing there is little chance of getting rid of it. Year by year the journals and societies help to swell the huge aggregate of mischief, and when an honest investigator like Hebra sets fairly to work to see what will do good and what will not, he has to waste years in useless or dangerous experiments before he can make *maison pette* of all this rubbish. Mr. Wilson has arranged alphabetically upwards of fifty remedies employed in this complaint, every one of them useless or nearly so.

Hebra uses arsenic internally in all the usual modes of giving it, but he also places great reliance upon external means, the principle of which seems to be a method very like that employed by Priessnitz. The patient is packed in a wet linen sheet, over which are laid a thick doubled blanket and a waterproof covering. He is allowed to drink water freely, and is kept in this state of maceration for three or four hours. The patient is then plunged into a cold bath, and, if possible, a cold douche follows the bath, after which he goes out for a walk. This process is repeated twice in the twenty-four hours. A light diet is ordered and no spirits are allowed. Hebra also uses the potass soap, which is rubbed on each patch of lepra till a slight bleeding comes on, the tar oils, and the solution of pentasulphide of calcium recommended by Vlemingkxt, which is rubbed on like the soap till excoriation is produced. The patient after using any of those takes a bath.

Of the external treatment there is little to be said. Hot baths once or twice a-week are often serviceable, and lotions of chloride of zinc sometimes give great relief. The empyreumatic oil of birch brought from Russia may also be safely recommended. I have given the liquor carbonis detergens a fair trial, but I cannot say that I have noticed any extraordinarily beneficial effects from it. Mr. Wilson considers the white precipitate ointment very useful in this complaint. Mr. Startin prescribes, when there is much inflammation, trisnitrate of bismuth, five grains to an ounce of water, used warm; later on he employs alkaline baths and ointment of the iodide of mercury. He also makes use of the sulphur fume bath and creosote ointment. For the solitary form of lepra he employs blistering.[1] Glycerine is prescribed by some practitioners, others consider oatmeal gruel very useful. I have not noticed any very appreciable effect from either.

Diet.—A patient suffering under this complaint is sure to ask about his diet, and particularly whether there is anything he must abstain from. So far as my experience goes I should say not, so long as anything like moderation was observed. It is quite as necessary in lepra as in any other disease to abstain from all very gross food, and from everything likely to produce a sense of heat, overloading, and constipation. I would, therefore, con-

demn too much pork, beef, sausages, curry, hard adulterated beer, and coarse spirits, like new rum or whiskey. I never saw high feeding do good, and I have certainly seen cases where it clearly appeared to have aggravated the symptoms. When a patient suffers from dyspepsia, irritability of the stomach, whether induced by arsenic or otherwise, from catarrh, influenza, &c., I would restrict him to a light but not a low diet. This is nearly all I have to say on the subject, but as others attach some more, some less, importance to diet, I proceed to give a digest of some of the principal points.

Mr. Wilson[1] says nothing of diet in his chapter on "Alphos," but, in his work on "Healthy Skin," he advises as a general rule that we should look suspiciously at potted meats, sausages, game, &c., that variety at a meal should not be indulged in, and that children should have plenty of good wholesome food, and plenty of variety in it. He thinks that people who give their children invariably one kind of food or too little of it, should be looked upon as dangerous lunatics, and made to understand that sickness and deficiency of food, with too little exercise and defective ventilation, are the cause of ringworm and scalled head being so common in schools. Mr. Wilson clearly thinks M. Soyer a better judge of diet than those mischievous obstinate people who starve children because they have been told by dear mama, or have read in Buchan, that children ought always to rise from table with an appetite, and such rubbish. He has no particular views as to the efficacy of any particular kind of food in skin diseases, for the simple but rather pertinent reason that very "little is known" on the subject.

Mr. Hunt seems to think that all restrictions whatever are unnecessary, and asks why the taste for so many different kinds of food was given to man, unless it was right for him to enjoy it. The answer is very simple, for the case is not fairly put. Most likely man living in a state of nature, leading the wild but anxious life of a hunter or fisher, sheltered at night in a cave or wigwam, and seeking his food by day amid ceaseless care and danger, could eat any kind of food he was likely to find. But he is not living in a state of nature, he has elected to lead a life of restraint, and he has to bear the consequences. The advantages derived from civilization tend inevitably to induce a state of the system which requires from every person more or less self-control in respect to diet; the evils of civilization create still more imperative demands, and therefore the great mass of mankind cannot be left to the unrestricted sway of their appetites, and if control be necessary in health it is still more so in disease.

Mr. Naylor recommends a very strict diet in lepra, excluding salads, sweets, salmon, pork, and shell-fish, alcoholic, and other fermented liquors. Dr. Hillier adds coffee to the Index Expurgatorius. Dr. Neligan says that a milk-diet should, if possible, be enforced, and that when it cannot be adopted, farinaceous articles should, as far as possible, enter into its composition, fresh meat or poultry only, plainly dressed, being allowed. The views of Mr. Startin, and others, on this subject have been already given.

Mr. Hunt speaks highly of the value of exercise in this complaint, and says that "many cases have occurred in which patients who, when pursuing a sedentary life, were martyrs to lepra, became comparatively free from the disease when engaged in active occupation in the open air."

As to the results of treatment or the prognosis of the complaint, I assume it is almost unnecessary to say that, however thoroughly all traces of an attack may be removed, the disease will tend to return. At the same time, under proper treatment, a long immunity can often be secured.

FISTULA IN ANO: OPERATION.

By P. C. LITTLE, F.R.C.S.I., Etc.

THE frequency of fistula in ano has been remarked by the earliest surgical writers. In our time it is probably more general, owing to the progress of a civilization favourable to the development of diseases which often originate this distressing malady. I need scarcely instance its rarity in the open country, compared with its almost daily occurrence in populous cities and towns.

The case which I now beg to lay before your readers seems to be a good example of this morbid condition, and to possess some noteworthy features.

February 17th.—I visited Mrs. K., æt. 37, wife of a sea captain, and mother of five hearty children. She complained of general impairment of health, caused, she believed, by two small openings near the anus, discharging pus, and indisposed to heal. She had never been ill until two years passed, when she caught cold by sitting on a stone near the sea, awaiting her husband's arrival. Soon after that she experienced a throbbing and uncomfortable feeling at the lower part of the bowel. During defecation, the latter protruded; occasionally became very painful; and at length remained in small nodules external to the anal outlet. About a year ago, she discovered a large swelling, with tenderness on pressure, towards the left side of the anus; and when at stool thought something scraped the bowel inside. Within the last two months, the tumour rapidly increased in size, pointed externally, and discharged a large quantity of fetid purulent matter. The abscess healed rapidly, but two pin-hole apertures remained open ever since. She now imagines there is constantly a splinter, or little bone, sticking in the rectum; complains of weakness, loss of flesh, appetite, rest, and spirits; inability to walk or sit with any comfort. She has not much thirst, no night sweats, and during her illness has only had one rigor, which preceded the evacuation of the matter. Her features are expressive of pain; her manner agitated; pulse weak and nervous, 78; bowels confined; heart, lungs, and other vital organs healthful. There is not any hereditary predisposition to disease in her family.

On examining the affected region, I observed, to the left of the anus, nearly midway between it and the tuber ischii, a dark, wrinkled, depressed patch of integument, about the size of a shilling, in the centre of which were two papillæ, nearly a half an inch apart. Slight pressure around them caused a drop or two of thin matter to exude. I passed a probe with some difficulty (the passage being narrow and tortuous) through one of the openings to the depth of about two and a-half inches, in the direction of the anterior wall of the rectum. At the same time, I introduced my left index-finger, well-oiled, into the intestine to meet the probe, which I found could move up and down in a cavity more than an inch in length on the front of the rectum.

By varying the position of the instrument and my finger, I tried to ascertain whether the fistula communicated with the gut, but I could find no opening, no papilla. I next examined the intestine with a bivalve speculum, and could discover no orifice, but noticed a good deal of congestion and hæmorrhoids above the anus, which were relieved by some bleeding caused by the introduction of the instrument.

As there did not appear to be any contra-indication, either in the condition of the patient, or from her family history, I proposed a surgical course for the permanent closure of the fistula, to which she at once assented. I therefore prescribed an oil-draught at bed-time, and a large warm-water enema early in the morning.

Next day, the 18th, I found her in a favourable condition for the operation, which I accomplished in this way: The patient lying in bed on her left side, her knees well flexed on her abdomen, and nates advanced towards me, I introduced my left index-finger, oiled, into the rectum, where I kept it. By the aid of her husband, I then completely suspended, with anæsthetic spray, the sensibility of the parts to be incised. I next laid the two sinuses into one, and quickly passed through the tortuous canal a bent director up towards the apex of the cavity, where I felt it with my finger. After that I cautiously slid along the instrument a curved blunt-pointed bistoury (Weiss'), and with one steady sweep cut through all the parts between the sinus and the anus. In this step I met with a diffi-

1 Diseases of the Skin. Sixth Edition.

culty. The gut was particularly tough and sensitive. I could not penetrate it with my nail on one side and the point of the director on the other. However, I attained my object by dropping my nail below the point of the bistoury to its cutting surface, where, by pressing gently, the instrument entered the rectum, met my finger, and so I divided all the structures without the least pain. Smart hæmorrhage ensued. I tried in vain to stop it with a plug of lint and compress, which seemed rather to keep the sphincter and bleeding-vessels open, and excited an inclination to defecate. At length I effectually arrested the flow of blood by the simple application of my finger to the vessels for about ten minutes, as recommended by Sir B. Brodie. I dressed the wound lightly from the bottom with a shred of oiled lint, applied a few folds of the same material soaked in cold water over the incised parts, and a T bandage to keep all in position. I finally administered an anodyne (tr. opii. gtt. xl.) to ensure confinement of bowels, if possible, for a day or two. I advised the wet lint to be re-soaked in cold water when necessary, and replaced; low diet, no stimulants.

I do not deem it necessary to give the daily record of the case. It may be sufficient to state that, the subsequent treatment consisted chiefly in linseed poultices for a few days; afterwards local stimulants; strict confinement to bed for about a fortnight; and regulation of the bowels.

I had daily to encounter two obstacles to recovery,—a strong indisposition of the sinus to cicatrize, and a tendency of the fresh cut surfaces to heal too quickly. Sluggishness of the fistulous track constitutes, according to Brodie, Pott, Crampton, and Roux, the principal difficulty in the after-management of such cases. Many approve of lunar caustic lightly applied along the sinus, as being the best means of promoting speedy and uniform healing. I am happy, also, to testify to its great benefit. In this case it hastened the desired union, and contributed to the restoration of the patient, which was completely accomplished in three weeks, without leaving incontinence of fæces or mucus, very generally sequences of this operation. The sphincter had regained its proper tonicity. The external piles had disappeared, and on digital examination I could discover no internal congestion of the rectum.

It has long been observed that fistula in ano usually coexists with, or is a consequence of some other disorder. Thus, it is frequently present with phthisis pulmonalis, tabes mesenterica, or scrofula; scirrhus of the rectum, or a general cancerous diathesis; cirrhosis, or obstructive disease of the liver; tumours pressing upon the portal, or hæmorrhoidal veins; constipation, uncomplicated piles, cold, or accident. In connection with any of the four last conditions, fistula in ano may be radically cured; whereas, associated with the previously-named constitutional or organic diseases, it scarcely admits of treatment, except palliative, applied locally or to the primary lesion. In many such instances the fistula is useful in the economy, as a diverticulum for abnormal blood-products, which otherwise might assail vital organs, just as an issue in the neck prevents cerebral congestion. Experience has proved that in those cases operation is unjustifiable, often hastens death; and, as regards the surgeon, would argue a want of knowledge of the pathology of this disease.

The co-existence of piles with fistula is very usual, and necessitates careful inquiry into the cause of the former antecedent to any surgical procedure to remedy the latter. If the piles be the reflection of disease affecting the portal or hepatic systems, the propriety of our operative interference with the fistula would be, indeed, questionable. If, however, the congestion of the hæmorrhoidal veins arise merely from excessive tonicity of the sphincter ani muscle, there could be no objection, *cæteris paribus*, to an operation for radical cure of the sinus, as adopted in the present case.

Here it appeared that the exciting cause of the piles and of the fistula was the same—cold, and that the active agent in the production of both diseases was the sphincter compressing the anal vessels which permeate it. The results of such constriction were—on the one side piles, and on the other ischio-rectal abscess, ending in fistula. The latter, like all fistulæ in the same region, had two great impediments to its closing up,—the ever-active sphincter, and the mucus character which the sinus assumes, as remarked in the *Quarterly Journal of Foreign Medicine*, &c., No. 8. The principles of treatment were therefore to effect—firstly, a temporary suspension of the sphincter's function; and secondly, the reduction to a healthy healing condition of the whole surface thus laid open. The first point was completely achieved by the knife, the second by the after-management already described.

Hospital Reports.

CITY OF LONDON DISPENSARY.

EPILEPSY CAUSED BY ATRESIA VAGINAE.

THERE is now a woman (36) under Dr. Oppert's care at the City Dispensary, who suffers from epileptic fits at the time of menstruation, these fits being the consequence of almost complete atresia vaginae. The fits are preceded by an aura, which consists in uneasiness first in the legs, rising afterwards to the chest, and giddiness. The latter lasts for some time, at last the patient completely loses consciousness, has foaming of the mouth, screams, and the limbs are violently shaken by convulsions. This often lasts only for ten minutes, and afterwards she suffers again from giddiness. The fits troubled the patient for the last eight months. She is thin, pale, has had no syphilis, and is otherwise healthy.

The vagina forms a *cul de sac*, and the finger can be only introduced as far as a good half inch, the mucous membrane easily bleeds. There is a very small opening left, through which a little blood oozes at the time of the monthly period.

The patient has been twice operated upon, the last time in Chelsea about nine months ago. How long the abnormal state of the vagina exists, cannot be clearly remembered, but it got gradually worse, especially after the operations. The patient is, therefore, not disposed to any further operations.

At present she takes only mistura menthæ.

Dr. Oppert thinks the case unique and very important, as a proof that epilepsy may be caused by cerebral conjestion, whereas many ascribe eplieptic fits exclusively to cerebral anæmia. As regards the treatment, an operation does not seem advisable even if it were permitted. But this case would be relieved by abstractions of blood at the critical times, combined with cooling medicines. In this way the time might be tided over till the climacterical period is reached. Dilatation by using a proper bougie, or Holt's dilator, will probably be tried.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL PRACTICE.

(Continued from page 206.)

Diseases of the Eye.—We find that of diseases of the eye fifty-five cases were admitted. We select a case entered as choroiditis. It occurred in a man who was suffering from secondary syphilis. There were several specific ulcerations on the legs. He complained of shooting pain on both sides of the head. Vision with the right eye was indistinct, and both pupils were irregular. A sclerotic zone surrounded both corneæ, that around the right being the most distinct. The globe was tense, and its mediæ were rather hazy. He was ordered syrup of the iodide of iron and cod-liver oil, and at night a pill composed of calomel and extract of hyoscyamus. Under this treatment the ulcers commenced healing, and he lost the pain in the head; but his vision was not improved, and "falling lights" occasionally appeared to descend to the ground from the outer angle of the right eye. When examined with the ophthalmoscope the right optic disc was found to be indistinct at its upper and

lower parts. The choroidal glow was less distinct than it should have been, and the choroid pigment was visible in various parts. The indistinctness seemed to depend upon œdema of, and slight deposit in, the connective tissue of the optic disc and neighbouring retina. A calomel and opium pill was now administered night and morning, and the zone disappeared from the left eye, and became less marked in the right, whilst the "falling lights" appeared less frequently. The eyeball became less tense, the mediæ clearer, and the ophthalmoscope showed considerable absorption of the deposit near the optic disc. He was discharged in an improved state of health, with the sight of the right eye returning. He could see objects on the opposite side of the ward, though he was unable to distinguish faces.

Diseases of the Organs of Digestion.—A case of abscess in the mouth, from caries of the teeth, proved fatal from frequent hæmorrhage. The patient had been suffering from alveolar abscess for some months, and the suppuration extended to the neck, where an abscess had been opened. When admitted, the whole of the right side of the neck was infiltrated with pus, and there were two discharging sinuses. The side of the face, as high as the zygomatic arch, was much swollen and indurated. He went on well for more than two months, when he suddenly had an attack of severe hæmorrhage from the mouth. Styptics were employed, but the bleeding frequently recurred, and he died in eleven days.

Eight cases are entered as ulceration of mucous membrane. One of these terminated fatally, and proved to be a case of diphtheria. The history was that of sore-throat for a month, but without evidence of syphilis. The left side of the soft palate was in a state of foul ulceration, surrounded by red sharply-defined edges. The right side of the palate was commencing to ulcerate, and the uvula was red and swollen. There was also ulceration at the back of the pharynx, as evidenced by the presence of suppuration. There was also pain during deglutition. Calomel-vapour was applied to the throat, and he went on well for about three weeks, when he became very low, and the throat very foul. He was ordered brandy, with a mixture of chlorate of potash, ammonia, opium, and bark; but he died soon after. When examined the body was in good condition. The whole of the right lung felt solid and heavy, and was in a state of congestive pneumonia. The bronchial tubes were full of exudation, even to their minutest ramifications. In the largest bronchi this exudation formed a complete cast to the tube. It was also found, though to a less extent, in the trachea and larynx. The left lung was natural, but congested. The soft palate, epiglottis, and fauces were covered with the same exudation as was found in the bronchi. On the soft palate there was the cicatrix of an old ulceration.

Thirty-nine cases of hernia were admitted, twenty strangulated, ten reducible, and nine irreducible. Three of the cases of strangulated intestine were reducible without operation; the gut being returned by the taxis, after the application of ice. Of the cases submitted to operation, six died. There were five cases of inguinal hernia, all of which were oblique and occurred in males. Four of these were acquired, and one was congenital. Three of these were enteroceles, and two enteroepiploceles; in one the omentum was ligatured and cut off, death resulting from peritonitis. Eleven were cases of femoral hernia; four in males, seven in females. In four cases the sac contained omentum as well as intestine, and in one omentum only; in three instances it was ligatured and cut off. There were five deaths; four due to peritonitis, and one to extravasation of fæces into the peritoneal cavity through an ulcer in the small intestine. One case of umbilical hernia in a female was operated on; recovery ensued. The sac was opened in every case. One patient with artificial anus was admitted in order that he might be fitted with an instrument.

A case is entered as constipation. The bowels had not been relieved for ten days, and vomiting had persisted for three days. When admitted there was great collapse and stercoraceous vomiting, the abdomen was tense, tympanitic and painful; pulse quick and weak, countenance sunken, but there was no hernia. After a purge and injection had been given, the bowels were freely relieved and the sickness stopped. In two days the patient was discharged at his own request.

For a case of cancer of the rectum colotomy was performed, but the patient rapidly sunk. It was the case of a woman, aged 38, who had suffered from difficulty in defæcation for seven years, and from the passage of blood and offensive matter. For eight months she had been almost unable to pass anything. On introducing the finger into the rectum, a hard ulcerated fungoid mass could be felt constricting the canal. The examination caused great pain. She was not much emaciated, and did not present the malignant cachexia. Amussat's operation was performed, but she gradually sank, and died in three days. There was no post-mortem examination.

(To be continued.)

Summary of Science.

(*Specially Edited and Compiled for the Medical Press and Circular.*)

By CHARLES R. C. TICHBORNE, F.C.S.L.,
FELLOW OF THE ROYAL GEOLOGICAL SOCIETY OF IRELAND, ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

MANUFACTURE OF GLASS VESSELS EMPLOYED IN CHEMICAL RESEARCH.

M. STAS says that ordinary glass vessels give up traces of the bases they contain to nitric and hydrochloric acid, even at ordinary temperatures. Hard Bohemian glass will resist this action, but is found very difficult to work, particularly in making flasks and such-like thin vessels, this difficulty being due to the great infusibility. He says that a glass having for bases potassium and calcium is easily worked, and is perfectly unacted upon by acids if it contains an excess of silica. Ordinary bottle-makers might take a useful hint from these remarks. No trace of arsenic (used by the makers in working this kind of glass) can be found in the vessels when made.

FLUORINE.

The *Chemical News* gives an abstract of M. Prat's paper upon this subject, which seems to have created some interest in the chemical world. M. Prat, besides other curious statements, says that he has succeeded in isolating the element fluorine, which, although often in the hands of the first experimenters, has so far baffled their attempts.

M. Prat regards the fluorides as in reality oxy-fluorides, and that the equivalent of fluorine is much higher than is usually supposed. He therefore considers that chemists have hitherto been mistaken as regards the composition of the fluorides and the theory of fluorine.

He says that the new equivalent of fluorine is 29·6. To obtain fluorine, according to M. Prat, fluoride of calcium (fluor spar) is heated with chlorate or perchlorate of potash. Oxygen is disengaged, and also a product which silver absorbs. The compound so found is floride of silver, insoluble in water, soluble in ammonia, and more rapidly altered in the light than chloride of silver.

According to M. Prat, this fluoride differs essentially from the soluble fluoride of silver of chemists, which is a compound of Ag. Fl., Ag. O.—not Ag. Fl.

Fluorine may be isolated, according to the author, by heating fluoride of lead either with nitre or with bromide of manganese. Oxygen and fluorine are evolved. A platinum alembic must be used, and the oxygen is removed from the mixture by passing over fragments of heated baryta. Fluorine is gaseous, almost colourless, of a chlorous odour, visibly fuming in the air. It blenches indigo and litmus, and immediately decomposes water at the ordinary temperature.

ARTIFICIAL FORMATION OF ONE OF THE BRAIN PRODUCTS.

M. Liebrich, in 1865, obtained from the brain a definite product, crystallizable, and containing phosphorous and nitrogen. This substance, on being treated with baryta water, yields

phosphoglyceric acid and a powerful base which he named nervine.

M. Bayer has recently demonstrated that it is a hydrate of oxethyl-ammonium in which three atoms of hydrogen are replaced by three groups of methyl.

M. Wurtz has produced the chloride of the base nervine by acting upon monochlorhydride of glycol by ammonia. The gold salt prepared from the artificial product was compared with the compound procured from the brain-substance, and they were identical in physical as well as in chemical appearance.

TEST FOR ALKALIES AND ALKALINE EARTHS.

M. Bœttger recommends an alcoholic extract of *coleus verschaffelti*, used in our gardens as an ornamental plant. The fresh leaves are agitated with absolute alcohol, mixed with a few drops of sulphuric acid. They are then left to digest twenty-four hours. Paper soaked in this tincture becomes red. The reagent is not influenced by carbonic acid, so that the earthy carbonates contained in water may be detected. A strip of the test paper held in a jet of coal gas becomes green from the presence of ammonia.

ON THE ACTION OF PANCREAS.

The above is the heading given by Dr. Dobell to an account sent by him to the Royal Society of his investigations in this direction.

The pig was the animal selected for the experiments, as being nearest in the character of its functions to that of the human subject.

On March 22, forty pigs were killed, and the pancreas was examined in each case immediately after death. The first ten had been fed two hours before they were killed; the second ten, five hours, and the third ten, nine hours, and the fourth ten had not been fed for two days. The pancreas in each group presented the same character in size, colour, and reaction. Each pancreas was cut open so as to show the principal duct, but in no case was there any fluid in the duct. Litmus, on being pressed sufficiently against the tissues, was in each case reddened.

The acid reaction is not found in the fat or the muscles of the animal. The reaction of the pancreas is always acid when it reaches the laboratory; but Dr. Collins, of London, found it alkaline in one lot of pigs killed in Hertfordshire. To discover the influence of the pancreas upon fat, the fresh pancreas of the pig, freed from all adhering blood and other extraneous matters, was cut into small pieces and mixed with lard, and to this mixture water was added. In the bruised condition the pancreas had an acid reaction. By stirring this mixture the fatty character of the lard disappeared, a thick white creamy fluid being found, which, on standing, solidified into a firm pasty mass. This emulsion rapidly putrefies, but remains as a permanent emulsion until putrefaction sets in.

The influence (the author remarks) exerted by the pancreas upon fats, appears to operate by breaking up the aggregate of the crystals of the fat (margarine, &c.) and altering its hydration. It alters the molecular condition of the fat, mingling it with water in such a way, that even ether cannot separate the fat from the water. The pancreas does not decompose it into fatty acid and glycerine, as shown by the absence of glycerine in the watery stratum, and the presence of glycerine in the "pancreatized" fat of an ethereal stratum.

If the watery extract of the pancreas is evaporated, pure, or mixed with malt dust, it may be kept good in the dry state.

RECENT RESEARCHES UPON OZONE.

Dr. Thomas Andrews has been endeavouring to clear up the mystery that hangs over this substance, particularly as regards the question—Is the substance that colours iodide of potassium and starch papers, ozone? as nitric acid and chlorine would have a similar reaction with that reagent. One of the most striking properties of ozone is its power of oxidizing mercury. On passing a stream of atmospheric air, which gave the usual iodide of potassium reaction for some hours over the surface of mercury contained in a U-tube, the metal was distinctly oxidized at the end, at which the air first came into contact with it. This experiment was not, however, considered conclusive, as mercury will tarnish and lose its mobility under the influence of many bodies besides ozone.

Ozone is destroyed by oxide of manganese, the air on passing over oxide of manganese no longer gives the reaction with iodide of potassium.

However, the most unequivocal proof of the identity of the body in the atmosphere with ozone was the action of heat.

Ozone obtained by electrolysis is quickly destroyed at a temperature of 237·6. Air passed through a vessel raised to this heat, no longer gave the reaction, although ozone was contained in it originally. On the other hand, when small quantities of chlorine or nitric acid vapours, largely diluted with air, were drawn through, the test papers were equally affected, whether the glass globe was heated or not.

M. Schonbein is also still working with his favourite subject. He says that the simultaneous formation of ozone and antozone may be illustrated in the following manner:—

Into a flask of 500 c.c. capacity, and three or four centimetres in diameter across the neck, a little ether is poured, and a red hot spiral of platinum is inserted. The platinum glows until all the ether is consumed. The presence of ozone is easily demonstrated by means of iodide of potassium and starch paper. To show the presence of antozone the flask is rinsed with a small quantity of ether, which will then be sufficiently charged with peroxide of hydrogen to give clearly the perchromic acid reaction (a beautiful blue colour). Some solution of bichromate of potash is placed in a test-tube, and the ether is poured from the flask on to the surface of this test solution. Antozone in the presence of water becomes converted into peroxide of hydrogen.

M. R. C. Lippincott proposes to use silver leaf for the detection of ozone. He exposes silver leaf to the atmosphere, kept moist by causing distilled water to pass over it, the water being conducted from an adjacent vessel by two or three threads of darning cotton. Whenever the ordinary test (potassie, iodide, and starch) indicated that ozone was present, some part of the silver leaf was oxidized.

STARCH OF MOLLUSKS.

M. Bizio says that the amyloidœ matter formed in mollusks is glycogen.

In contact with white of egg or casein lactic acid fermentation slowly sets in.

POISONOUS COMPOSITION OF "THE MOTHER OF PEARL ADDRESS CARDS."

M. A. Ebert, in a letter dated from Germany, draws the attention of the editor of the *American Journal of Pharmacy* to the poisonous nature of the pretty mother of pearl cards, which are so fashionable just at present. The crystalline effect is produced by a coating of acetate of lead (sugar of lead). The public should therefore be upon their guard, that they do not get into the hands of young children, who will almost certainly be induced to suck or chew them, from their sweet taste.

THE REFINING OF CRUDE CAMPHOR.

Crude camphor comes from China and Japan, the latter being much whiter and purer than that from China.

The impurities are chloride of sodium, sulphur, the remains of leaves and laurel-wood, a small quantity of tarry matter, and a quantity of water, which varies from two to ten per cent. The camphor is refined in mattresses, which are placed upon a properly-constructed brick furnace, carrying hearths supplied with sand-baths. Each furnace is provided with a movable grate, by which the operations can be controlled.

The crude camphor broken small is mixed with three to five per cent. of quick-lime recently slacked, when it contains sulphur, one or two per cent. of iron filings are added. These produce a whiter and firmer product.

It is then sublimed in the mattresses, but requires great care in regulating the heat.

Japan camphor loses in refining one to four per cent., and China five to six per cent.—*Bulletin de la Societié Chimique Paris.*

FERRATE OF POTASH.

M. Merz prepares this salt by passing chlorine rapidly through a solution of five parts of potash in eight parts water, and containing about one-fifth part of its volume of a solution of perchloride of iron. The temperature rises to about 50° C. The strongly-coloured liquor is then filtered. This solution will keep for some considerable time.

ON THE SOLUBILITY OF ÆTHER IN SYRUP AND THE FORMULÆ OF SYRUP OF ÆTHER.

MM. J. Regnauld and Adrian (*Journal de Pharmacie*) have been trying some experiments upon the solubility of æther in syrup, and recommend from their experiments the following formula for this preparation. We may mention that this syrup of æther enjoys some repute in the practice of French phar-

macy—it has been introduced into the French Codex. The authors state that the formula of the latter work is not constructed upon a knowledge of the solubility of æther. They propose the following proportions :—

Sugar . . .	440
Water . . .	490
Alcohol . . .	50
Æther . . .	20

The whole is introduced into a flask and shaken until the sugar is dissolved.

ON THE ACTION OF LEAD UPON DISTILLED WATER.

The question has been re-examined by M. Bœttinger. Metallic lead is, as we know, attached and dissolved by distilled water. The author attributes this action to the presence of ammonia, which exists in the ordinary distilled water. Lead filings were rapidly dissolved by ordinary distilled water, but if this water was kept at a boiling temperature for an hour, or if it was redistilled from a few drops of sulphuric acid, it no longer acted upon the lead. It is necessary to employ pure lead, as a small quantity of tin prevents this action by virtue of its electro-positive nature in regard to lead.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 25, 1868.

MR. ORTON'S REPORT ON CHOLERA AND THE WATER SUPPLY.

THE advocates of the hypothesis that last year's cholera "explosion" was due to the Old Ford water have had a long innings ; they have ridden their hobby-horse as far as they possibly could, and now that the jaded beast is utterly exhausted, it is but fair that those who have all along looked doubtfully on their proceedings should be quietly heard. We have already given, at considerable length, the conclusions arrived at by the Officer of Health for the City of London, and pointed out that they are diametrically opposed to the so-called "water-theory." That able and learned officer—by far the first chemical and physiological authority of the Health Officers—is fully competent to maintain, unaided, his opinions against the plausible arguments of his opponents. But it is clear that he does not stand alone, and that other gentlemen with opportunities of studying the outbreak find the hypothesis in question as unsatisfactory as he does. We have before us the report of the Medical Officer for the Limehouse District (Mr. Thomas Orton), and we notice that he, too, unequivocally rejects the assumption that the water was the main cause of the "explosion." Not only so, but he does not hesitate to push home the arguments that occur to him, and to point his remarks with personal observations that make them unusually piquant. We think he is quite justified in adopting this style, since the water theorists have forced their doctrines on public attention with a pertinacity that leaves no chance of being heard to any who do not follow in their wake, or depart widely from the stereotyped dulness of official records. In a word, they have been lead away by a taste for the sensational, and cannot fairly complain of those who clothe replies in an equally popular garb.

From the first it has been well-known that many of the London Medical Officers of Health were not prepared to subscribe to the doctrine so persistently urged upon public attention, although they were content to wait before giving expression to any positive conclusions until they should have had time to investigate the facts. It must further be confessed that the *facts* some of these gentlemen have recorded have not yet received the attention they deserve at the hands of those whose hypothesis they appear to invalidate. Thus it was long ago stated by Dr. LETHEBY that the Old Ford water contained "one-third less of organic matter in June, when cholera broke out, than in the following December, when it ceased." Again, it was stated, on the same authority, that not a single case occurred amongst the fifty residents of the London Hospital, nor amongst the 400 ordinary patients of that institution, though all the water they drank came from Old Ford. Then we have heard that at the East London Workhouse, with 300 inmates, there was only one case of cholera, and that one imported from a distance. Further, in the Eastern Division of the City of London, in 161 houses with 1732 inhabitants, supplied by the Old Ford water, there was but one death; the remaining 4495 houses, with 40,673 inhabitants, supplied by the New River Company, had sixty-two deaths. At Stamford-hill and Clapton, exclusively supplied from Old Ford, there was little or no cholera. These and other facts mentioned by Dr. LETHEBY, Dr. CORNER, Mr. ORTON, and others, certainly require explanation, and we regret that the advocates of the water theory have hitherto made no effort to grapple with them.

The facts themselves are most striking; they have been mentioned again and again by those under whose observation they came; they have never been questioned; yet those whose theories seem inconsistent with them make no sign. It is time they abandoned their speculations, or attempted to reconcile them with the facts of the case.

Mr. ORTON'S report affords them the opportunity, for it reiterates these statements, and adds to them others equally significant. We trust, therefore, it will receive the consideration that the importance of the subject demands. By way of showing the nature of the further evidence against the water hypothesis accumulated by Mr. ORTON, we add some of his statements, taken at random from the pages of his report. He tells us that in one family three moderate beer-drinkers died, while five children who, in the mother's words, were "*doing nothing but drinking water all day*," escaped from even diarrhœa. Again, he says, that of 600 inmates of the Stepney Union, only six died. Of 400 children in the Limehouse establishment, there was not a case of even diarrhœa. Of many other establishments similar results are recorded and commented upon with considerable skill. In this way Mr. ORTON brings together the drinking habits of 1800 persons—some of them infants at the breast—and draws from his laborious researches the following conclusions: 1. That the ordinary drinkers of Old Ford water were not affected by it differently than in former years. 2. That the drinkers of the alleged foul water were singularly exempt from the epidemic of 1866. 3. That the drinkers of fermented liquors

were the principal victims; and 4. That as numbers who perished drank neither stimulants nor the suspected water (infants), the cause of the explosion remains to be explored.

The report of Mr. ORTON, which extends to fifty-seven pages, contains much other matter in relation to this and other theories that have been propounded. We confine our observations at present to these few prominent facts, and the conclusions he draws from them, in order to place before our readers, as briefly as possible, the objections to a theory which has excited much alarm, and which certainly demands further consideration before it can be definitively accepted as sufficient.

Those interested in the subject will not fail to turn back to our epitome of Dr. LETHEBY'S report (MEDICAL PRESS AND CIRCULAR, January 15, 1868, p. 55), and carefully weigh the evidence there given, and so powerfully corroborated by Mr. ORTON.

It is to be regretted that so little consideration was given to these facts before the sensation paragraphs of last year were disseminated through the country, and that at present so many journalists should have committed themselves so thoroughly to the water theory that the other side has little chance of being heard. With the impartiality with which we endeavour to treat all such discussions, our columns will be open to communications, and we shall be glad to further comment upon them as occasion may require.

DR. JOSEPH ROGERS.

THIS name is familiar as a "household word" to every Poor-law Medical Officer in the Kingdom. No one has been more earnest in promoting Poor-law Reform. No one could more worthily have supported the dignity of the profession in the constant war that has been waged by the Strand Guardians of the Poor. Yet, Dr. ROGERS at length retires from his arduous duties under circumstances likely to kindle indignation in the breast of every Englishman who hears the tale. A majority of the Board of Guardians suspended him, and asked for his compulsory resignation on the ground of incompatibility, &c. A respectable minority memorialised the Poor-law Board in his favour. He demanded a public inquiry, and was supported in that demand by the unanimous vote of the vestry, where he has laboured for nearly a quarter of a century.

"Of course his demand was agreed to," is the natural exclamation of those who know nothing of the sublime indifference of the Central Board to the laws of justice or the wrongs of Medical Officers. It must be told—this tale of shame. The magistrates of Gwyder House held a *secret* inquiry into the statements of the Strand Guardians, and agreed that Dr. ROGERS should be asked to resign; since, although there was no charge against him as to his professional duty, his removal might contribute to the harmony of the Union.

It must be added that this precious Board of Guardians is about to be broken up and re-constituted.

The matter cannot rest here. The Metropolitan Poor-law Medical Officers' Association has passed a resolution of confidence in Dr. ROGERS, and pressed him to continue to act as their President. The Workhouse Association, at a meeting on Friday week, expressed condemnation of the authorities, and recommended that the question should be brought forward in Parliament.

Dr. ROGERS will have the sympathy and support of the whole profession, and of almost the whole press of Great Britain.

We say almost, because, to the great surprise of many, the *Journal of the British Medical Association*, which has lately affected so much interest in the Poor-law service, has at present refrained from any protest against the injustice that has been perpetrated.

Notes on Current Topics.

Inspiration.

THE second Pentecost which has fallen upon two of our Medical contemporaries, *soi disant* "the leading journals," has lately taken the form of an inspiration more suitable to the "Jeames" of the *Morning Post* than to the solemnity of Medical law-givers. The competition for a quotation in the daily journals with all the halo (and all the advertising connection) which that distinction imparts to the journalistic source, has given birth to a series of pseudo-medical chronicles of the pains and aches of crowned heads and Royal off-shoots, which will be read in future years with wonder as to what their oracular phrases may mean. With incredible *acumen* our contemporaries have calculated the public pulse, and supplied the desired medical stimulus in the most judicious doses, and we can no longer afford to neglect the department of Medical Flunkeyism which is so active in the columns of our contemporaries. As there is no European King or Prince sick enough to merit a paragraph (except the Pope, and he has been "done" this week already), we have been favoured with the following important and exclusive despatch as to the health of the Emperor of Borrioboolagha, which, it is to be hoped, may in some measure relieve the prevailing anxiety in European diplomatic circles :—

HEALTH OF THE EMPEROR OF BORRIOBOOLAGHA.

The poignant sorrow with which the subjects of his most supreme Majesty have learned of the appearance of certain obscure symptoms of dacryo-cysto-seringo-kata-kleisis may receive some alleviation from the statement that the symptomatology of that affection has not been developed to the full extent. We believe we will be found to be accurate in the announcement that his most supreme Majesty has experienced an amelioration of the symptoms which were formerly more urgent than they are at present, and that *if* the series of manifestations which have given universal concern to the medical attendants of his supreme Majesty should cease to be observed a cessation in these symptoms may be anticipated.

"A Victim to his Candour."

A QUACK named Campbell, described in his own hand-bills as a Member of the Royal College of Physicians, and a Licentiate of the Apothecaries' Company, has been figuring as a receiver of stolen goods in the London police courts. He had, it appeared, having extracted from an artizan who stood beside him in the dock all his available money, received in payment for medical services a quantity of stolen paper, and having been sent to jail for a week he protested against such an injustice to him, describing himself as "a victim to his candour." It is greatly to be regretted that the same desirable result cannot be arrived at in respect of some of "the victim's" coadjutors without the intervention of an unfortunate artizan.

St. Thomas's Hospital.

THE hope conveyed to her Majesty the Queen by the Governors of St. Thomas's Hospital, that her Majesty would be pleased to lay the foundation-stone of the new hospital, has been graciously responded to, and a day will be fixed for the ceremonial after the 12th of May.

The Farnham Workhouse.

THE details of maladministration, neglect, and inhumanity which raised such a ferment in the public mind a few months ago, turn out, on the investigations of Mr. Lambert and Dr. Edward Smith, whose report has just been issued, to have been altogether unreliable. The workhouse has been found to be, perhaps, just as dirty, ill-ventilated, and badly cared as many other similar institutions probably are, but not more so, and the inspectors report "that most of the serious charges have been disproved, while others have been shown to be exaggerated." To those who can regard such statements without bias and in calm consideration, it will not be wonderful that the heated statements and opinions of the press should appear to require modification. At the same time that the papers have done good service in calling attention to abuses which might have gone on for any period unchecked, still it is very well that on the verdict of men of such character as Mr. Lambert and Dr. Smith, it should be understood that workhouses are not such pandemonia as they have been represented.

Liability of Medical Men to Conspiracy.

THE liability of medical men to accusations involving a breach of their professional confidence, has been most painfully illustrated in a case tried in the Crown Court at Antrim last week, in which a Mr. William Crossden sued Dr. Hume, of Crumlin, for a criminal assault on his wife in the discharge of his medical duties. The issue was sustained by very explicit evidence on the part of the plaintiff and his wife, and defended by the most vehement and positive sworn denial of the defendant.

As the learned judge remarked—"If the plaintiffs' story be true, he had sustained a gross injury; if the defendant's story be true, the plaintiffs were conspirators of the basest kind." In view of such uncorroborated evidence the jury disagreed.

We cannot pretend that the commission of the offence charged would be incredible because the accused happens to be a medical man, although we can take credit for the marked infrequency of such charges against our profession in the face of personal temptation such as no other persons are ever subjected to. It is not, however, an extraordinary principle which we enunciate when we say that a greater weight of evidence should be demanded by juries against medical men than against other persons. By the very nature of their avocations, medical men are exposed to the plots of conspirators in this line, and are necessarily not in the position to produce exculpatory evidence, and we think that any less proof than the credible evidence of a third, and disinterested witness, ought not to be held sufficient to attach to a medical man the guilt of the greatest crime which, morally or professionally, he could commit.

Collegiate Economy.

THE financial purgation to which, as we announced some weeks since, the Royal College of Surgeons of England is to be subjected, has had its first effect in an unexpected direction. The Council of the College have determined on the motion, we believe, of Mr. Partridge, that the College funds shall be no longer expended on Council dinners. The merit of such self-denial is unfortunately rather marred by the consideration, that under the auspices of the Council such an extraordinary allocation of collegiate funds could have ever occurred. That it did occur, and that to the extent of about £400 a-year, is the strongest argument in favour of monetary reform, which ought to have an ample field where such an expenditure was permitted.

Formation of an Army Medico-Chirurgical Society.

THE military members of the profession at Portsmouth and its neighbourhood initated last week an effort to establish amongst the members of their branch of the profession an interchange of opinion and experience, such as our numerous medical societies accord to their civil brethren. The isolation of small numbers of army medical officers, essential to their duty, must always restrict the professional intercourse of the many to a few special localities. Portsmouth, with its extensive depôts and numerous administrative departments, and its vicinity to Southampton and Netley, is specially suited to such an effort, and we hope yet to record a success which will encourage similar organisations in Chatham and elsewhere.

On Wednesday afternoon, a number of gentlemen met in one of the wards of the Garrison Hospital, used for the performance of church services, to hear the opening address delivered by Deputy Inspector-General, Dr. Gordon. In the course of his observations, of which we have an abstract in type, but are compelled to postpone its publication till next week, Dr. Gordon reviewed the progress of military medicine and surgery, and the contributions of celebrated army medical officers to its literature. The address was well received, and the inaugural meeting separated with an *eclat* which promises well for the future of the society.

The Physics of the Nervous System.

RESEARCH into this interesting subject is about to receive an important extension at the hands of Dr. Richardson, of London. As President of the Medical Society, that gentleman has announced his intention of contributing in the early part of each sitting a series of experimental illustrations in this direction, for the completeness and value of which Dr. Richardson's name is a guarantee to the profession.

The Medical Supervision of the Mountjoy Convict Prison.

THE result of the discussion in the House of Commons, which we reported in full a couple of weeks since, in which it was roundly charged that the Irish Government had got rid of Dr. McDonnell because he remonstrated against the inhuman treatment of Fenian prisoners, was the immediate appointment of a commission to investigate the case of the prisoner who died lately under suspicion of neglect on the part of the medical officer appointed in Dr McDonnell's place. We understand that the commissioners—Mr. Lentaigne, Mr. Tufnell, and Mr. Robinson, have reported that there was no neglect in the case, and that accusation is thus set at rest. The facts, however, to our mind, reflect little credit on the Irish Government, and the decision of the commissioners cannot mitigate in the least degree the character of the entire affair.

In August last, the occasion of Dr. Banon's death was taken to get rid of the remaining visiting physician—and why? Because, according to Lord Mayo's statement, the change was advised by Mr. Murray, the director. Thus the Chief Secretary admits to have acted solely at the suggestion of an official who was himself the person principally inculpated in Dr. McDonnell's humane protest, without inquiry as to the merits of the question at all, and to have, at the bidding of the person for whose supervision the office of visiting physician existed, turned out the medical officer in the exercise of that supervision, and substituted an official who, from his position, could exercise no check at all, and whose qualification was that he is the son of the Chief Secretary's agent.

The Contagious Diseases' Act.

THE extension of the legislative provisions respecting the propagation of contagious diseases was the subject of a discussion in Parliament last week. On an inquiry from Major Dickson, Sir John Pakington observed, that it was expected that efficient hospital accommodation would be ready in Dover in next May, and that then the Act would probably be extended to that town. Viscount Lifford has given notice of his intention to inquire whether it would be extended to London.

Guinea-Worm.

EVER since the Abyssinian expedition was decided on, we have heard, from time to time, more or less veracious accounts of the dreaded Dracunculus. Some of the descriptions circulated have partaken altogether of a sensational character, and if half they portrayed were trustworthy, we have, indeed, reason to rejoice that our troops have escaped the tortures some lugubrious prophets declared were in store for them. Not very much is really known of the subject in this country. Travellers, however, have described the parasite and the symptoms it gives rise to, as well as some methods of extracting it.

Staff-Assistant Surgeon Africanus Horton, who has served several years with Her Majesty's forces on the Gold Coast, where the Guinea-worm is common, has just published his observations on the subject in the form of a pamphlet, in which he not only describes the progress of the disease caused by the worm, but announces a radical cure! And this cure is no difficult or painful operation, no violent or dangerous poison. An old-fashioned household drug, the only drawback of which is a disagreeable taste, has only to be swallowed and the worm will be destroyed, the excruciating agony it has caused subside, and the patient probably remain unmolested by such enemies for years! Dr. Horton says "there are two main results obtained by the use of his remedy. These are *rapidity of cure* and *total annihilation of the worm*," and they are obtained in all three stages of the disease. He writes—"I have seen cases where patients were suffering from the most excruciating pains, which entirely prevented them from moving about, being for the time perfectly crippled, who took the remedy; and no sooner was the physiological effect manifest than the pains were dispelled, and the individual was enabled to walk about with ease and freedom."

Who after this would hesitate to swallow a drug because it was nauseous? Dr. Horton makes no secret of his remedy. It is merely assafœtida, and if this drug really possess such marvellous powers the sooner the Government send a quantity to the Gold Coast the better. By all means let us supply our troops there with a remedy equal to the "total annihilation" of the Guinea-worm.

Dr. Horton relates six cases treated by him while stationed on the West Coast of Africa.

The Public Health.

THE mortality returns are still unusually favourable, the deaths continuing to be under the average in almost all localities. The annual rate of mortality for the whole kingdom last week was 24 per 1000. It was 22 per 1000 in London, 29 in Edinburgh, and 24 in Dublin; 27 in Bristol, 23 in Birmingham, 30 in Liverpool, 28 in Manchester, 22 in Salford, 23 in Sheffield, 27 in Leeds, 25 in Hull, 24 in Newcastle-upon-Tyne, and 31 in Glasgow.

Manchester exhibits a remarkable decline of mortality, especially in the number of deaths referred to zymotic diseases. Measles, however, prevails in one of the workhouses just outside the municipal boundaries.

Sheffield and Hull have an epidemic of small-pox. In London the total number of deaths registered during the week was 1309, being less by 312 than the estimated average for the eleventh week of the year. The deaths from zymotic diseases were 228, the average number being 325. There were 11 deaths from small-pox, 36 from measles, 12 from scarlatina, 8 from diphtheria, 54 from whooping-cough, 36 from fever, and 14 from diarrhœa. Of diseases of the chest, we note 191 deaths from phthisis, 140 from bronchitis, 73 from pneumonia, and 73 from diseases of the heart.

As we had not space in our last impression to summarise the prior week's returns we may hear state that in the metropolis the deaths registered during the week before last numbered 1610. This is 279 less than the average number for that week, corrected for increase of population.

The annual rate of mortality was 24 per 1000 in West London, 22 in North London, 22 in Central London, 22 in East London, and 22 in South London.

The deaths from zymotic diseases were 259, the corrected average number being 331. Twenty-four deaths from small-pox, 39 from measles, 16 from scarlatina, 7 from diphtheria, 61 from whooping-cough, 48 from fever, and 12 from diarrhœa were registered.

"Three deaths from small-pox were recorded in the west, 8 in the north (where the Small-pox Hospital is situated), 5 in the east, and 7 in the south districts. One fatal case was registered in the Holborn district. Four deaths from small-pox occurred in the sub-district of Woolwich Arsenal. Eleven deaths from measles were recorded in the west, 8 in the north, 3 in the central, 7 in the east, and 10 in the south districts. Fifteen deaths from whooping-cough were registered in the west, 7 in the north, 8 in the central, 9 in the east, and 22 in the south districts. Four children died from whooping-cough in the workhouse at Greenwich.

The deaths from fever were at the annual rate on 10,000 living of 6 in West London, 6 in North London, 10 in Central London, 9 in East London, and 9 in South London. In calculating these results, the deaths in the London Fever Hospital were referred to the districts from which the patients were brought.

"Last week 6 deaths from fever were registered in the central districts; of these one death occurred in the district of Clerkenwell, 3 deaths were in the district of St. Luke, and 2 in the district of East London (St. Botolph and Cripplegate).

"One hundred and fifty-four deaths occurred from phthisis, 138 from bronchitis, 76 from pneumonia, and 62 from disease of the heart."

SCOTLAND.

The returns of the northern kingdom for the month of February have been issued. During that month 2170 deaths were registered in the eight principal towns of Scotland—Glasgow, Edinburgh, Leith, Greenock, Dundee, Aberdeen, Paisley, and Perth. "Allowing for increase of population, this number was 265 under the average mortality of the month during the last 10 years. The epidemic and contagious class of diseases proved fatal to 469 persons, constituting 21·6 per cent. of the total mortality. This rate was exceeded in Dundee and Leith, from the fatal prevalence of measles in the former, and scarlatina in the latter town. Of 113 deaths by fevers, 54 were from typhus and 50 from enteric. Scarlatina and whooping-cough caused each 87 deaths, measles 69, croup 30, apoplexy 42, paralysis 37, diseases from inflammatory affections of the respiratory organs 381, besides 268 from consumption. Seventy-one deaths were registered from violent causes, two from *delirium tremens*, and five from intemperance. Of the 2170 deaths, 943, or 43 per cent., were those of children under five years of age; in the smallest of the eight towns—Perth—the proportion of these early deaths was only 28 per cent. of the whole mortality, but in the largest—Glasgow—it was 50 per cent. In Leith it was 48 per cent., and in Dundee 44 per cent. Eleven of the persons who died during the month had passed their 90th year; the eldest was the widow of a millwright, aged 101 years. The births registered in February in the eight towns were 3003. Of these, 300 were illegitimate, being in the proportion of one illegitimate in every 10 births. The marriages for the month numbered 493, which was 20 below the average of the corresponding period of the last 10 years. The month was characterized, in a meteorological point of view, by a disturbed barometric pressure, unexampled high mean temperature, large amount of rain, great force of wind, and continued westerly, strictly W.S.W. direction beyond parallel. The highest mean temperature was recorded at Leith, 44 deg., and the lowest at Aberdeen, 41·6 deg. The large number of 26 rainy days out of the 29 occurred at Glasgow, at Paisley and at Greenock; the depth of rainfall at Greenock was 11·74in., or nearly twice that of Glasgow and Paisley. Edinburgh was at the head of the mean pressure of wind column, with 7·40lb. on the square foot; while Paisley was at the foot, with only 1·03lb. on the square foot—a curious fact, if true, seeing that the wind was blowing from Paisley to Edinburgh."

Dr. Cockle proposes to cure fatty tumours by injecting them from time to time with liquor potassæ, diluted with two-thirds of water. We understand that the suggestion has already been put in practice.

Dr. W. H. Day has just re-printed a paper on Gastrodynia. He would restrict this term as much as possible to pain of a neuralgic character.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

Thursday, February 20, 1868.

Mr. William Adams read a paper entitled, "In what cases is Lateral Curvature of the Spine Curable? and what are the directly Curative Means."

He insisted that no confirmed or persistent curvature of the spine, however slight, can exist merely as a functional affection, but that in every instance a spinal curvature is necessarily associated with, and dependent upon, certain structural changes, proportionate to the degree of curvature and its duration. He drew a broad line of distinction between these cases and cases of *weak spine* with a disposition to curvature, which he described as a functional affection depending upon muscular debility.

He relies for diagnosis entirely upon the altered relations of the angles of the ribs in the dorsal region, and of the transverse processes in the lumbar region.

The author did not consider that the ligaments or muscles underwent any important changes in the early stage of the affection. He stated that the curable stage of lateral curvature was limited to the early period of the affection—probably one or two years—when the structural changes are slight and recent, and when we have youth and growth in our favour. If this opportunity of curing a spinal curvature be lost, it rapidly becomes incurable, and capable only of being arrested by mechanical support.

Dr. Dick observed that when the spine had a lateral curvature, the bodies of the vertebræ were compelled to rotate with every movement backwards or forwards of the spine; in fact, he had proved this to be a law of any elastic rod. Any pressure applied to the sides of the spine only increase the rotation; consequently, in order to be of any use, pressure must always be applied to the back.

Mr. Steevens did not believe that rotation of the vertebræ was an essential element in curvature of the spine, but that this was generally dependent on some condition of the muscles.

Mr. De Meric thought the division into functional and structural curvatures a very good one; the former class was very easily cured, and it was from these cases that so much credit was often derived.

Dr. Cleveland suggested the probability of structural changes in the spine beginning at a very early period, from the faulty positions in which children were carried by nurses.

Mr. Adams, in reply, said he thought that the benefit supposed to be derived from division of muscles was really due to the long continued confinement afterwards necessary; he did believe the muscles either caused or kept up curvature; but in other cases of deformity, where the muscles were really in fault, as in wry-neck, great advantage was to be gained from subcutaneous division of the tendon of the offending muscle. He considered mechanical pressure as a directly curative agent, but it must be kept up for years, and must be applied either posteriorly or diagonally; he agreed with Dr. Dick that lateral pressure was productive of mischief, increasing the rotation of the spine, which was invariably present. Lateral curvature was not uncommon at 3, 4, and 5 years of age, and at these ages it rapidly became incurable, and there was no hope from treatment unless continued up to 20 years of age. A good plan with children was to tie them to a sort of cradle, such as he had seen commonly used by the peasantry in the South of France.

MEDICAL SOCIETY OF LONDON.

Monday, March 2, 1868.

Mr. Henry Smith, President.

Mr. Francis Mason showed a calculus surrounding a piece of bougie which his colleague, Mr. Barnard Holt, had removed from a man at the Westminster Hospital. The patient was 41 years old, and had had stricture of the urethra for 25 years. Fourteen years ago a bougie was passed, a part of which remained in the bladder, this was extracted through the perineum, but the stricture continued as bad as ever, an abscess formed about a month ago which burst in his perineum. Through the sinus urine had constantly dribbled. Mr. Holt introduced a probe into this sinus, and at length came upon the calculus, which was of the lithic acid variety, and which surrounded a piece of bougie about an inch long. Mr. Holt thought the stone was situated in a false passage by the side of the urethra. Mr. Mason also showed a piece of bougie removed from the bladder of a patient with the ordinary lithotrite.

Mr. William Adams then read a paper "on the treatment of wounds on the antiseptic and subcutaneous principles." The object of the author was to show how far the antiseptic and subcutaneous principle may be relied on separately in the treatment of different classes of wounds, and to what extent they should be combined. The author then proceeded to describe the various methods which have been devised for dressing open wounds, including incised and lacerated wounds, compound fractures, &c., pointing out how far each one depended upon the subcutaneous principle. He then spoke of the treatment of dressing wounds with lint dipped in the patient's blood, and with lint soaked in compound tincture of benzoin, also with collodion, and with the more recent preparation introduced by Dr. Richardson, called "the styptic colloid." Mr Adams spoke of a case of amputation of the foot in which he

had used this styptic, and that union by the first intention had taken place through nearly the whole of the wound. In many cases that had been treated at the Great Northern Hospital the wounds had been washed with ether without using water, and with the very best results. The author then referred to cases in which suppuration had been established. He dwelt upon the advantages of lime water applied to suppurating wounds, and believed the chief virtue of the so-called canon oil in cases of burns were due to this ingredient. He concluded by arranging the various kinds of wounds into six classes, and gave a general summary of the treatment in each class as based on the antiseptic and subcutaneous principles.

In the discussion that followed, Dr. RICHARDSON made some most interesting observations. He first spoke of the germ theory of M. Pasteur. He believed that water was a bad application to wounds. The great desideratum was to prevent oxidation. Wounds presented a different appearance at different times. This, he thought, was due to the variable moisture in the atmosphere, or to barometrical pressure. Surgeons, he said, would, fifty years hence, select their days for their operations on that account.

Mr. Hunt, Dr. Sansom, the President, and others, took part in the discussion, and the author having replied, the meeting adjourned.

CONVERSAZIONE AT THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

ON the 12th inst., the President and Fellows of this Corporation gave a conversazione, in the Faculty Hall, where some 250 visitors were entertained. There was a great display of professional, scientific, and artistic objects, and several hours were spent in their examination, and in social intercourse. Refreshments were provided in the library of the hall. Prior to the adjournment thither the company assembled in the large Hall and were addressed to the following purport by the President, Dr. Fleming:—

On the part of the fellows of Faculty, I beg to assure you that it gives us great pleasure to find that the invitations issued for this conversazione have been so generally accepted. This numerous meeting of our professional friends, from all parts of Scotland, is ample proof that these reunions are appreciated, and are fulfilling the ends the Faculty had in view in instituting them. The duties of a public body like this are various and important. There can be no doubt that the object of our forefathers in instituting the medical corporations of Scotland, was entirely the protection and welfare of the community. The phraseology of the charters shows that any benefit to our profession entered little, if at all, into the consideration of the subject. The protection of the public from illiterate and empirical practitioners, who seem to have abounded in the days of our foundation quite as much as they do now, necessitated the calling in of the aid of the scientific part of the profession, and of conferring on them certain corporate duties. It has been the fashion of late years to call these duties rights and privileges. I confess I cannot see on what principle or just adaptation of language they have so been designated. Those public duties could only be performed through the agency of corporate bodies; and the question at once arises—how have these corporations performed the trust confided to them? I have only to look around on this numerous, intelligent, and educated assemblage of physicians and surgeons for an answer to the question. A large proportion of your number are alumni of the Glasgow School of Medicine and Licentiates of this Faculty; and, while we have good reason to be proud of you, I trust you have no cause to be ashamed of us. Of late years, I am glad to say, a great and very favourable change has taken place in the condition of our profession. The thirty years' conflict is now matter of history, and a new and brighter era dates from the Medical Act of 1858. Some sanguine spirits have been disappointed at the results which have followed the labours of the Medical Council brought into existence by that Act, and cynics have sneered at its pretensions and importance; but considering the chaos in which it found the government of our profession, the very imperfect Act of Parliament it had to administer, the conflicting difficulties with which it was surrounded, I affirm, without fear of contradiction, that it has done wonders; and I appeal to every man of twenty years' standing in the profession for confirmation of this assertion. While, then, gentlemen, we have reason to be satisfied with our professional and social advancement of recent years, such progress ought only to stimulate us to increased exertions for the future. Where is the great body of the profession to look for the initiative in such exertions? Certainly to the medical corporations. The wisdom and foresight of our forefathers founded, in 1599, one of these institutions—viz., this Faculty—in this city; and wonderful as has been the progress and prosperity of this district, I am proud to think that medical progress has not lagged behind, and that we have now one of the largest and most distinguished medical schools of the United Kingdom. With all deference to our friends of the University, I must be permitted to say, that for the origin and first progress of this school we are mainly indebted to the prescience and fostering care of this Faculty. I can assure you that we were never more desirous than now to devote our means and our influence to the encouragement of medical education and medical science, the only true foundations on which our prosperity, whether as individuals or as a united profession, can rest. I trust, therefore, our brethren will continue to rally around us, the natural centre of professional convergence in the West of Scotland.

The PRESIDENT then introduced to his audience Dr. Weir, who four years ago, on a similar occasion, read a paper on the history of the Faculty, and who was about to supplement it with a further communication on the same subject. The President felt that the subject was far from exhausted, and looked forward with pleasure to future papers by the same author.

Dr. WEIR then read his paper, which he called a "Second Chapter of the History of the Faculty," in continuation of the paper read in 1864. After alluding to the founders of the Corporation, Dr. Weir said that his remarks this evening would have reference chiefly to the life and professional labours of some of the members of the faculty in the eighteenth century, who had attained some rank and celebrity in the profession as physicians and surgeons, and who were worthy by their discoveries or improvements in medicine to be remembered by their successors as shedding some degree of lustre and honour on the Corporation. Unfortunately, the minute books of the Faculty from 1682 to 1733 were destroyed in the latter year by an accidental fire, and for a period of fifty years the records were awanting. From the minute of the first meeting held after the fire, it appeared that at that time there were eighteen resident members, besides a large number of licentiates, practising in all the towns throughout the four counties over which the Faculty at that time had jurisdiction. From that year to the end of the century 134 members entered the Faculty, making, with 18 above mentioned, 152 in all. Of these he might mention Dr. Johnston, Professor of Medicine in the University about the year 1745, whose name appeared as president from 1737 to 1739, and who was an active member for several years; and Dr. Hamilton, Professor of Anatomy and Botany in the University, and whose father and grandfather had both occupied the same chair, and who were descended from the family of Hamilton of Preston, an ancient branch of the ducal house of Hamilton. Dr. Hamilton was president from 1734 to 1737, and was the granduncle of the late Sir William Hamilton, the distinguished metaphysician. Of Dr. Cullen it was scarcely necessary to say anything to the present audience, except in regard to his connection with the Faculty. At an early period of his life he was apprenticed to Mr. John Paisley, a surgeon of extensive practice in Glasgow, and thus acquired the rudiments of his profession in this city. After leaving Glasgow he was appointed surgeon to a merchant ship sailing to the West Indies. On his return he studied with great ardour in London and Edinburgh. He then practised two years in the parish of Shotts, afterwards in Hamilton, and ultimately in Glasgow. While in Hamilton, the afterwards celebrated William Hunter was his pupil, and latterly partner, and to the end of his life esteemed his old master and friend very highly. It appeared from the Faculty minutes, that though Cullen applied in 1736 to be admitted a "freeman" of the body, and a thesis was appointed for him to write upon, from some unexplained cause he did not appear for examination. He graduated at Glasgow University in 1740, and settled in Glasgow in 1744, in which year he was admitted a member of the Faculty. He immediately began to lecture on the practice of medicine, materia medica, botany, and chemistry, the celebrated Dr. Black being his pupil and assistant in his chemical prelections. On the resignation of Dr. Johnston, in 1751, Cullen succeeded him in the Chair of Practice of Physic, having, however, been elected President of Faculty some years previous to this. In 1756 he was appointed to be Professor of Chemistry in the University of Edinburgh, and filled successively the Chairs of Institutes of Medicine and Practice of Medicine in that University. Cullen was the first, or among the first, to deliver lectures in English, Latin having

previously been the language used for that purpose. He was unquestionably a man of talent and great industry—a deep-thinker, accurate observer, and accomplished physician. His teaching and doctrines, particularly his great doctrine of excitement and collapse, had for a long time a most extensive influence on the practice of medicine, and his system of nosology has been a text-book of the medical schools almost down to our own day. His "First Lines of the Practice of Physic" was sufficient to place him in the highest rank in the profession, and to give him an imperishable name. Dr. Joseph Black, Professor of Chemistry, as has been already mentioned, was a pupil of Dr. Cullen, took his degree in 1754, and was elected President in 1759; and again in 1765 he became Lecturer on Chemistry, after Cullen had gone to Edinburgh. After many experiments, he propounded the celebrated doctrine of latent heat, which is still identified with his name. He was appointed Professor of Chemistry in Edinburgh University in 1766, and died in 1799. Drs. Johnston, Hamilton, Cullen, and Black, if they did not actually found the School of Medicine in Glasgow, added very greatly to its reputation, and had the two last distinguished men remained in Glasgow instead of removing to Edinburgh, it is difficult to say what might have been the relative position of the two medical schools at the present day. Dr. Weir, after alluding to the career of Dr. John Gordon, another distinguished member and President of the Faculty, sketched the life of Dr. John Moore, the well-known author of "Zeleuco," and the father of Sir John Moore. Educated in Glasgow, he became a zealous member of the Faculty, and practised in Glasgow for twenty years. Prior to settling down in the city he had travelled through many parts of Europe in company with Douglas, the eighth Duke of Hamilton, and published an entertaining account of his travels. He is a voluminous writer, though he published only one professional work, entitled "Medical Sketches." He became "Visitor" of the Faculty in 1757, and died in 1802. He was admittedly a man of great literary attainments and high reputation. He had much correspondence with the poet Burns, who greatly admired his literary productions. Tobias Smollett, the celebrated historian and novelist, was an apprentice to the same surgeon, Dr. Gordon, to whom Dr. Moore had also been articled. He was never a licentiate of the Faculty, though his name is entered in the Faculty records as an apprentice. The celebrated Dr. William Hunter received his preliminary education in Glasgow University, and was for a short time a partner of Dr. Cullen, but soon removed to London, and there acquired the great name in the profession, of which you are all aware. He was never an ordinary member of the Faculty, but he was the second individual upon whom the honorary fellowship was conferred. This title was awarded to him in 1751, when he was at the height of his fame. He bequeathed his very large collection of anatomical and obstetrical preparations to the University of Glasgow, thus forming the Hunterian Museum. After referring to Dr. Peter Wright, Dr. Weir next alluded to Mr. Samuel Hunter, a licentiate of the Faculty, long editor and co-proprietor of the *Glasgow Herald* newspaper. He served in Ireland as surgeon to the North Lowland Fencibles, afterwards became a captain in the same regiment, major in the Glasgow Sharpshooters, and afterwards commandant of the 4th Regiment of Highland Local Militia; and in 1820 commanded the Corps of Gentlemen Sharpshooters raised at the time of the "Cotton Rebellion." He was a Magistrate of the city, well-known and respected by all classes, Tory, Whig, and Radical. He died in 1839. In concluding, Dr. Weir said that he might have dwelt a great deal longer on names which he had mentioned, had time and other conditions permitted. Some of the names he had mentioned, had shed a lustre on medicine and the collateral sciences, which still continued to shine; and he sincerely trusted that the younger members of the profession might be stimulated by the exertions of their predecessors to follow their example, to emulate their great achievements, and, by discoveries and improvements in the healing art, reap the grateful thanks of their contemporaries, and the esteem and gratitude of succeeding generations.

At the conclusion of this interesting paper, a vote of thanks having been moved by Professor ANDREW BUCHANAN, and seconded by Dr. CAMPBELL, of Largs, was carried unanimously.

Dr. GAIRDNER, Edinburgh, also briefly addressed the meeting. He considered nothing could be more interesting to the profession than the history of their predecessors in the walks of professional industry, and as a small contribution to their information on that point, proceeded to state a few facts in relation to the connection which so long existed between surgeons and barbers. This connection, according to the learned doctor, originated in the association of offices in monasteries, where, in consequence of the prevalent use of the razor, and the love of good cheer, shaving and phlebotomy were two operations greatly in vogue, and thus from convenience became to be discharged by the one operator. In Scotland this connection was done away with at a very early period, but in France it continued, at least in a modified form, down to the period of the great revolution. Concerning this connection the speaker went on to state that his late brother used to relate a curious anecdote, which he had heard when a young man from Chaussiere, the eminent French professor, who was in the habit of narrating how, after the outbreak of the revolution, he called in a carpenter to cut down a partition which existed in his class-room, and which separated the students of pure medicine and surgery from those who were merely there as barbers, exclaiming *Plus de distinction entre ceux qui rasent et ceux qui ne rasent pas*—down with all distinction between those who shave and those who don't. Chaussiere, however, used very candidly to add, if the distinction between the two was broken down the class went down also, the students of medicine not being sufficiently indoctrinated with the then prevalent theories about liberty, fraternity, and equality to take kindly to their brethren of the razor and lather-pot. Dr. Gairdner concluded by congratulating the Faculty on possessing such a historian as Dr. Weir, and also on having a history so worthy of being recorded.

The following evening the medical students of Glasgow were invited by the Faculty to a similar entertainment.

SURGICAL SOCIETY OF IRELAND.

FEBRUARY 28TH, 1868.

Mr. PORTER, Vice-President of the College, in the Chair.

PRESENT:—Drs. Benson and Richardson, Hon. Secs.; Fleming, Jameson, White, H. Kennedy, Eustace, Ferguson, R. H. Moore, C. Moore, Minchin, Morrogh, F. Kirkpatrick, Guinness, Jacob, Wilson, W. Stokes, Mapother, Wharton, Roe, H. G. Croly, W. D. Moore, McDowell, Willis, Barker, Tyrrell, O'Grady, Brady, Swan, Lalor, Cronyn, Telford, Usher, F. T. Porter, J. Benson, Torney, Hewitt, Barry, Walter Smith, Croly, Macnamara, Hargrave, Morgan, Tufnell, M'Grath, and Burne.

Mr. H. G. CROLY offered the following remarks on

FRACTURE OF THE PATELLA.

He said—At the last meeting of the Society, I read a paper on fracture of the patella, and I commenced by saying, that I did not consider it necessary to make any apology for bringing it under notice, when I found the following passage in an English work on Surgery: "The author believes from what he has seen that fractured patella is one of the opprobria of English surgery." I wont say how far I agree with that notion or not, but the words are not mine, and finding such a view taken by others, I thought I was justified in bringing under your notice a case which I had treated by a method not generally practised in this country. With regard to the union of the fragments in that case, there was a misapprehension on the part of some of the members. It was believed I said that there was bony union in the case. I said nothing of the kind. I said if I had an opportunity, which I did not wish to have, of macerating the man's patella, I would be able to prove whether bony union had taken place; but I confined myself to stating that there was firm union of the parts. What I said about the closeness of the union was also misunderstood, and accordingly I addressed a letter to the surgeons of the "Royal George," who were called on by the Admiralty to examine this man and report upon his case. The following is the reply which I received:—

"February 16th, 1868.

"DEAR SIR,—In reply to your's of the 14th inst., respecting the present condition of Mr. Harris' leg, I may observe that it was the decided impression and remark, both of Dr. Ireland and myself, that we had never seen an instance of fractured patella in which the broken portions had been kept so well together, and united so closely as in his case—posteriorly they must be quite in apposition. In our report on Mr. Harris, we recommended that he should not be appointed for duty for a period of six months at least, but

at the end of that time we hoped that he would be fit for service.—I am, dear sir, your's faithfully,

"HENRY LONEY, Surgeon."

An assistant-surgeon in the Royal Navy, who visited this patient a few days ago, called upon me subsequently, and I asked him to write me a letter stating his impression of the case. He writes as follows:—

"20, Lr. Gardiner-street, February 20th, 1868.

"DEAR CROLY,—I called yesterday to see Mr. Harris of the Revenue cutter 'Racer,' who sometime since fractured his patella, for which I believe he has been under your care. I have seen a great number of these fractures, both during the time I was a student, and since I entered the Naval service, but never met a case before, where such close union had taken place, in fact without an accurate examination it would be rather difficult to say which patella had been fractured. This one case alone ought, I think, to demonstrate the superiority of the 'Hook' treatment over the old splint and bandage.

"Wishing you a like success with all your cases.—Believe me, your's sincerely,

"THOMAS H. ATKINSON, Assistant-Surgeon,
"H.M.S. 'Martin.'"

I beg also to remind the society that I said I did not wish, in bringing forward this subject, to decry the ordinary methods used by Sir Astley Cooper and other eminent surgeons in the treatment of fractured patella; that I had seen good results from the usual modes of treatment; but that in this special case the separation was so great after several days as to allow the two fingers to go between the fractures, and the patient would not submit to the bandages, saying he could not bear them, although he was warned that the consequences would be permanent lameness. I then told him about the hooks, and that I had had no experience in using them, but he agreed that they should be tried, and I brought forward the case only for the purpose of showing their usefulness, and without intending to disparage other methods. I also referred to a table published by Mr. Pyle, House-Surgeon of the Middlesex Hospital, in which he records ten cases treated by Malgaine's hooks, and ten treated by the ordinary methods. In not one of the former was there irritation, and there was close union; while in all the other cases there was an unsatisfactory result. In the *British Medical Journal*, a fortnight ago, I find a case recorded by Mr. Campbell de Morgan, in which he had used Malgaine's hooks successfully; and in the *Medical Times and Gazette* of February 15th, 1868, I find two cases of fractured patella treated with Malgaine's hooks—one recorded by Mr. Partridge, of King's College Hospital. He says—"One of the most curious of fractures is fracture of the patella. If a patella be broken transversely it unites by bone if properly treated. Now, this has been denied—nay, is still denied by the majority of surgeons in the United Kingdom. But all other fractured bones unite by osseous tissue: then why not fractured patella? In truth they are no abnormalities; they unite by good sound bone. But then, to effect this result the fragments must be kept in close apposition. By the ordinary plan this cannot be accomplished, consequently no good bony union can be obtained." Then Mr. Partridge says that "Malgaine's method for producing union between the fractured fragments of the patella is entirely forgotten (not given up) in the land of its birth, yet the following cases will fully testify that the hooks have been and are still a great success at King's College Hospital:—*Case* 1.—Jane H., 46 years of age, admitted to King's College Hospital April 2nd, 1866, with transverse fracture of the right patella. The accident happened in consequence of a false step made while descending a flight of stairs. The fragments separated three-fourths of an inch. The house-surgeon put in the hooks above, and brought the fragments into close apposition. Little pain, no swelling of knee, and no irritation about the wounds made by the hooks in the skin. She was removed on the 15th of May, and it was found that the fragments had perfectly united by bone, at least it then appeared so. The patient presented herself in two months. No trace of fracture could be detected, and she said she could walk as well as ever. Alfred B., 36 years of age, admitted January 4th, 1868, with transverse fracture of the right patella. He slipped backwards, suddenly straightening his leg, the break happened. The fragments separated two fingers' width. It was found that the left patella was broken transversely six years previously; the pieces were four inches asunder. This left patella had not been treated with hooks. The house-surgeon applied the hooks, and brought the fragments into close apposition; a straight splint was applied, and up to the present time, February 10th, no injury has been caused by the hooks." With regard to the way in which this fracture generally occurs, I quoted from Holmes' "System of Surgery" a statement that there was a difference of opinion between French and English surgeons. Sir William Fergusson says—page 391 of his admirable work on "Practical Surgery"—"The patella is frequently broken, the injury being in general the result of violent action of the muscles in front of the thigh, as when a person endeavours to prevent himself from falling forward." Liston believes transverse fracture to be the result of muscular action. Sir Astley Cooper says "fractures of the patella commonly happen in the transverse direction, and are caused by the powerful action of the extensor muscles of the leg. Mr. Adams, in his valuable paper on abnormal conditions of the knee-joint, in Todd's Cyclopædia, says—"Longitudinal fracture of the patella is rare, and this and the comminuted are generally the result of direct violence; and, although the transverse fracture may depend on a similar cause, still the violent contraction of the extensor muscles is the most frequent cause of the accident. A case is recorded of a soldier who broke his patella in endeavouring to kick his sergeant. In the operating theatre of the Hôtel Dieu, both the knee-pans of a patient were broken by violent spasms of the muscles which followed an operation for the stone. For the production of a transverse fracture of the knee-pan, the extensor muscles of the leg need not act with convulsive force, their ordinary action being strong enough to produce the effect in question when the body is inclined backwards and the patient is in danger of falling upon his occiput."

Sir Charles Bell says—"The fracture of the patella, or knee-pan, happens in consequence of a *sudden*, and very strong, *action of the four muscles* which are inserted into it, while the knee is in that degree of *flexion* that the patella is raised upon the convex surface of the lower end of the femur. Sometimes the patient observes that the crack of the fractured bone was *before* he fell to the ground; while, for the most part deceived in the circumstance, he *supposes* that in striking the ground the knee-pan has been fractured." Syme, in his "Principles of Surgery," says—"Transverse fractures occur from inordinate contraction of muscles. When from direct violence it is comminuted."

Miller, in his system of surgery, says—"The simple transverse fracture is the result more frequently of muscular action than direct injury." Gray, in his work on anatomy, says—"Fractured patella, from muscular action, is transverse. When from direct violence, it is fractured obliquely, or comminuted." Pirrie, in his principles of surgery, says—"It is a popular mistake that the fall is the cause, whereas it is the consequence of the accident." In the new surgical dictionary, by Lane, the author says—"Transverse fracture of the patella, though it may originate from a blow, is in all common cases the result of violent action of the muscles." Mr. Holthouse, in his article on fractured patella, says—"Of all the bones of the skeleton, the patella is most liable to be broken by muscular action." Again, "Fractures of the patella, by muscular action, are always transverse." Costello, in his Cyclopædia of Surgery, says—"Fractured patella, by violent action of the muscles, are always more or less transverse." Having seen many cases of fractured patella, I was always impressed with the idea that the patient's knee did not strike the ground before the fracture took place, and that the fall was occasioned by the fracture, and not the fracture by the fall. I have two patients now here who can be examined by the members of the Society at the close of the meeting. One of them was treated by the hooks, as I have already stated. In the other case the man slipped down an inclined plane, and, in trying to save himself, fractured the patella, and then, when he went down, fell on his head.

Mr. HEWITT said he attended at the hospital with Mr. Croly when he first treated this case, and saw the fractured patella put up in the usual manner with the figure of eight bandage and the splint. He had seen, through the kindness of other surgeons, several cases of fractured patella, and he saw one remarkable case, which Mr. Croly would remember, in which the bone was fractured three times, ligamentous union having occurred, and the bone being subsequently broken across. He saw this case put up with Malgaine's hooks, and there could be no doubt that the fragments of bone had been brought closely together. The patient merely complained of a tickling sensation, and said that the bandage which he had on before, and which was applied with the greatest skilfulness and accuracy, gave him pain, uneasiness, and distress, whereas the hooks gave him none whatever. Mr. Croly had not brought

forward this case with a view to disparage other modes of treatment, but to show that in some cases Malgaine's hooks would be found of great use. In this instance they produced no irritation whatever, and brought the fragments together in the most perfect manner.

Dr. KENNEDY observed that fracture of the patella had been known to have occurred from muscular action in cases of tetanus. With regard to bony union in such cases, he should say it was extremely rare. So far as he was aware there were none of these cases which presented any appearance of callus; and in a bone like the patella, where there was very little covering, it struck him as strange that there had been no case brought forward of anterior callus if there were true bony union. Under the circumstances he thought it was not yet uncontestably proved that bony union had taken place. Even in the case brought forward by Mr. Croly on the last night there was a distinct sulcus in the patella.

Dr. BENSON said there was a specimen in the museum of a transverse fracture of the patella in which bony union had taken place. He thought Dr. Kennedy was mistaken in saying that there was a distinct depression in the bone itself. He (Dr. Benson) examined the man and could not find the slightest separation between the bones. It was true one fragment was elevated a little above the level of the other, and in the cast of the joint it gave the appearance of separation; but as far as he could observe in the living person there was no separation between the fragments. On running the finger over the patella in one direction a little eminence, caused by one fragment standing a little higher than the other could be felt; but in running the finger in another direction it was not perceptible. After having seen many hundreds of fractures he had never met one in which there was more perfect union than the present; he did not mean bony union, but a firm union.

Mr. MORROGH had been a quarter of a century in the service, and had seen a great many fractures of the patella generally arising from muscular action. He did not remember ever seeing such perfect union as existed in this case, at least judging from the cast. He paid particular attention to the observations of Mr. Croly the other night, and he did not hear him use the words osseous union.

Dr. MAPOTHER observed that on physiological grounds he would be inclined to argue that bony union could not take place in cases of fractured patella; but these theoretical grounds were set aside by what he remembered to have read in Packard's able translation of Malgaine's work on fractures. Many dozens of instances of transverse fracture of the patella were stated there as having been united by true callus, proved by dissection. The translator agreed with the French author in thinking the fracture was generally caused by falls on the knees, and direct violence, rather than by muscular action. He thought Mr. Croly's paper, an abstract of which only he had heard, was extremely valuable, for the circumstances of fracture of the patella differed completely from those of fracture of a long bone such as the femur. In the latter the muscular tendency was to make the fragments over-ride; in the former there was no muscular action to produce that effect, and something was required to keep them together. Mr. Croly was not the first to use Malgaine's hooks in Dublin. He (Dr. Mapother) had seen the hooks in St. Vincent's Hospital which had been tried there, but he believed not successfully in Mr. O'Ferrall's practice in that hospital.

Dr. BARKER observed that the specimen in the museum was one of half a patella, in which there was a transverse fracture united by bone. As it was the only specimen introduced into that large museum within twenty-five years, it proved that bony union in cases of fractured patella was very rare indeed.

Mr. B. W. RICHARDSON said that he had seen Mr. Hamilton use Malgaine's hooks in the Richmond Hospital many years ago.

Mr. FLEMING said that during his connection with the Richmond Hospital he never saw Malgaine's hooks used, and he had seen a great many cases of fractured patella which turned out satisfactorily. After a time, however, when the limb was used, the ligamentous structure stretched, and he would strongly suspect, even in the case brought before the society, that a similar result would follow, if great care were not observed. In one case which came under his notice there was partial ankylosis of the joint, that is to say it was incapable of flexion, and with a view to remedy it, mischief was done by attempting to flex the joint; the result was that separation took place between the fragmentary portions, although some months had elapsed since the occurrence of the accident. Malgaine's hooks had been used in Steevens' Hospital on one or two occasions, but for a series of years he had not seen them used there. In treating a case of fractured patella by Malgaine's hooks, he would be apprehensive that a portion of the integument might dip itself within the interspaces of the fragmentary portions. They knew that in some of these cases, no matter how closely the fragments were brought together, a sulcus was left which might produce mischief.

Mr. CROLY, in reply, said he had never seen Malgaine's hooks until he got them from Weiss, of London. Some of the books in giving directions for using the hooks said that they should be stuck into the upper edge of the patella. That was, however, objectionable, for it was apt to slip down. If that mistake, which was committed by the books, were made by the surgeon the operation would fail, and he would be obliged to take out the hooks, for they would tear the skin over the patella. Having taken care to ascertain the exact place of the patella, he sunk the hooks in above it, so that the cavity of the hooks embraced the edge of the patella; the lower hooks he fastened into the ligamentum patellæ, and then put on the screw and brought the fragments together, taking good care to prevent the skin being dipped in. Malgaine asserted that the figure of eight bandage and the collar were objectionable, because one would depress the upper edge, and the other would depress the lower, the result being that the anterior ends were not brought in contact, while the posterior ends were. The figure of eight bandage would tilt the ends forward, whereas, by the hooks, and he could say this even from having used them only once, the contact was perfect. He should be sorry to say positively that bony union had taken place in a bone which was not considered to belong to the skeleton; but if surgeons say that a vertical fracture can unite, he did not see why the same should not be said of a transverse fracture. Dupuytren said he dissected a patella, and found pyramids of bone between the fragments. He thought, therefore, it was quite possible that bony union could take place. He did not say there was ligamentous union in this case; neither did he say there was bony union. He had his own ideas on the point however, and he promised the society if the fragments ever separated to his knowledge he would inform them of the fact. As to allowing the patient to bend the knee soon it was an error. He did not think there was any fear of ankylosis in these cases.

(To be continued.)

Correspondence.

PLURAL BIRTHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following case of plural births may be interesting to your readers, if so I shall feel obliged by your inserting it.—I am, sir, your very obedient servant,

GEORGE M. MAYBERRY, M.D.

Riversdale, Kenmare, Feb. 24, 1868.

"Margaret Gallivan, labourer's wife, aged 33 years, of delicate and emaciated appearance, married eleven years, had four children previous to her present confinement, the youngest over two years old, got ill in labour on the night of the 6th inst.; called on me to see her, Friday the 7th inst., when I found she had given birth to a child sometime before I arrived; she was much exhausted, and showed great general debility; quick and weak pulse; considerable thirst; had no labour pains then. I found the abdomen prominent, and on examination per vagina perceived with some trouble and difficulty the natural presentation of a second child; she was so weak, I had to keep her up with strong beef-tea and wine. She continued without any pains or progress in labour until Sunday the 9th inst., when pains came on, labour had so far advanced that I ruptured the membranes, being unusually thick and tough, and soon after she was delivered of a second child. Her weakness continued to an alarming extent; beef-tea, wine, brandy, &c., continued, given her frequently, and increased; all labour pains ceased, although the abdomen was still a little prominent, no presentation to be felt at this stage, and had much difficulty in keeping up her strength until Monday morning, the 10th inst., when she was delivered of two more children, having rather smart previous pains. In all four, one son and three daughters, all alive and baptised. Very soon after the fourth infant was born the placentas came away without any trouble or hæmorrhage. The placentas were in size apparently in

proportion to that of the four infants; the weight of the latter were, average, three pounds each. I must observe, the placentas of the 1st, 2nd, and 3rd child born appeared, although separate, so knitted together at their base that one could not be separately taken away, if extraction of the first was considered prudent. The placenta of the last child born was altogether separate. The poor woman's debility was so serious throughout her illness, that with difficulty crowds of her friends and acquaintances could be kept from entering her little cottage, considering, as they did, she was dying. The mother is now quite recovered from her alarming confinement.

"1st child born lived 8 hours.
"2nd do. 60 hours.
"3rd do. 44 hours.
"4th do. 16 hours."

Riversdale, Kenmare, February 24th, 1868.

SIR,—The enclosed communication I have the honour of receiving with £4, the charitable and kind donation of the Queen, to be given Margaret Gallivan, the poor labourer's wife near this town, on whom I had been lately in attendance, when she gave birth to four children. I am happy to say the woman, who I have seen this day, is now out of danger.—I am, sir, your very obedient servant,

GEORGE M. MAYBERRY, M.D.

"Buckingham Palace, London,
"February 21st, 1868.

"Major-General Sir Thomas M. Biddulple has received the Queen's commands to forward to Dr. Mayberry the enclosed post-office order for £4, payable to him, and to request that he will have the goodness to cause the amount to be safely delivered to the wife of Timothy Gallivan, as a donation from her Majesty to assist her after her confinement of four children at one birth, that circumstance having been brought under her Majesty's notice, through the application which Dr Mayberry addressed to Sir Thomas Biddulple on the 10th inst.

"To George M. Mayberry, Esq., M.D.
"Riversdale, Kenmare, Ireland."

NOTICES TO CORRESPONDENTS.

Messrs. BLACK, Edinburgh.—No review of the book you mention has yet appeared. We have it now under notice.

CONSANGUINITY.—A correspondent sends us the following question, which he hopes may be answered by some of our numerous readers, whose opinions may have been formed by careful observation:—"If first cousins are healthy, and intermarry, will their offspring suffer as a consequence of their relationship, or will such union in any way contribute to disease?"

Dr. SMITH, Monkwearmouth, is thanked for his kind expression for our success.

Dr. S., Buttevant.—It is not necessary.

Communications, &c., received from S. Atherton, Esq., Thalto Heath; T. Clarkson, Esq., Ripley (enclosure); E. F. Bean, Esq., Ashburton (enclosure); Rev. W. H. Cartwright, Dudley (enclosure); Messrs. Dear, Esq., London (enclosure); Mr. Redford, Masbro'; Mr. Lyson, Wath; Dr. Camps, London; Executors of Dr. Cust, Barnard Castle (enclosure); Dr. Agar, Ponders End (enclosure); Dr. McGrigor Croft, London (enclosure); J. Blake, Esq., Taunton (enclosure); Dr. Bridge, Wellington (enclosure); R. H. Barker, Esq., Hungerford (enclosure); Dr. Shaw, Flanderswell (enclosure); Dr. Corbet, Stanford-le-hope; L. Dashwood, Esq., Norwich; Dr. Couch, Swansea; Dr. Von Tuszelmann Rumson (enclosure); Dr. Chater, Tenby (enclosure); Mr. J. Baker, Exeter (enclosure); J. Smith, Esq., Monkwearmouth (enclosure); Dr. Barker, Brighton (enclosure). Dr. Rose, Diss; the Secretary of the Harveian Society; Dr. Dysart Portlegnone; Dr. O'Sullivan, Dunmore East; Dr. Crean, Clonmel; Dr. Warren, Ringaskiddy; Dr. Duigan, Mullingar; Dr. Ridley, Tullamore; Dr. Kenny, Killeshandra; Dr. Peirce, Newcastle; Dr. Kearney, Carndonagh; Dr. Rawson, Carlow; Dr. Salmon, Castlepollard; Dr. Pentland, Drogheda; Dr. Furnell, Limerick; Dr. Walsh, Clogheen; Dr. Keirnan, Carrick-on-Shannon; Dr. Lane, Newtownlimavady; Dr. Williams, Dingle; Dr. Ryan, Ballinacally; Dr. Frame, Coomber; Dr. Mulligan, Newry; Dr. Wanall, Adare; Dr. Gillespie, Clones; Dr. Reynett, Portlaw; Dr. Burke, Limerick; Dr. Barter, Cork; Dr. Haines, Midleton; Dr. Johnston, Riversdale; Mr. Sprott, Matlock (enclosure), &c.

APPOINTMENTS.

Dr. ALEX. SILVER has been appointed Assistant-Physician to Charing-cross Hospital. It is also stated that he will take the chair of Forensic Medicine at that institution.

Dr. MAUNSELL, of 53 Harcourt-street, has been appointed to the chair of Botany in the Ledwich School of Medicine and Surgery, vacant by the death of the late Dr. Askens.

DEATH.

PUREFOY.—On February 16th, at the Medical Officers' Quarters, Calcutta, on his way home, Assistant-Surgeon J. R. Purefoy, Royal Bengal Army, the loved and lamented son of T. Purefoy, Esq., M.D., &c., Lucan, Co. Dublin.

ESTABLISHED 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50, Lincoln's-inn-fields, W.C.

MR. J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c. (KING'S COLL.), has always upon his books a large number of desirable investments and available openings for Medical Men commencing their professional career. Gentlemen wishing to relinquish practice can be introduced without delay to competent successors with means at their disposal.

Mr. Langley devotes his prompt personal attention to the negotiations entrusted to him, and treats confidentially and with care all matters relating to professional business. The strictest reserve will be practised in all the preliminary arrangements and no expense incurred (except in special cases) unless a negotiation be completed.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

A prompt and just system secured a large measure of success to the General Partnership and Commercial Agency Business formerly conducted by him at his City offices; this has for some years been transferred to Lincoln's-inn-fields, and he has invariably adopted the same equitable policy in the more professional matters placed in his hands. Thus his experience in the management of large commercial undertakings, combined with his medical, scientific, and literary acquirements, enable Mr. Langley to guarantee that all matters of business placed in his hands will be carried out without delay, and with an equitable regard to the interests of all the parties concerned. As an arbitrator on matters of dispute between professional men, Mr. Langley has had great experience, and he can refer to numerous cases in which he has been the means of preventing expensive and tedious litigation, and in which his awards have been made rules of her Majesty's Courts at Westminster.

Mr. Langley can also refer to the Professors of his College, Members of Parliament, Clergy, Merchants, Bankers, and others, as a guarantee of his integrity and honour in all negotiations entrusted to him.

Full information as to terms, &c., sent free on application.

Office Hours from 11 till 4; Saturdays from 11 till 2.

LONDON, S.W.—An old-established Practice for Transfer. Receipts upwards of £600 a-year; capable of great increase. There is a good honorary appointment associated with the practice, and clubs bring in £75 per annum. The house, with detached surgery, is in a pleasant situation, contains 12 rooms; rent, £52, 10s. Satisfactory reasons for leaving, and references afforded to a leading hospital surgeon. Address, X. 197, Mr. Langley, as above.

WILTS.—Country practice in a pleasant district for Sale Population, 3000. Only one opponent. Receipts £400, including transferable appointments yielding £100. There is a Railway Station within easy access, and the patients are chiefly of a good class. Address, X. 90, Mr. Langley, as above.

PARTNERSHIP.—A third share of a good country Practice for Transfer. Present receipts £1500. The incomer must be accustomed to good society, and should have £1000 at his command. Address X. 248, Mr. Langley, as above.

PARTNERSHIP.—A third or a fourth share in an old-established and increasing Practice is open for negotiation. Receipts £1400 a-year. Address X. 116, Mr. Langley, as above.

DEATH VACANCY.—The succession to a Country Practice in a pleasant district in the Home Counties is open for negotiation. The receipts have averaged £380 per annum. Appointments £102. Address X. 242, Mr. Langley, as above.

£850 a-year.—For Transfer, an increasing Practice in a large and improving Town in the North of England. The Practice is easily and inexpensively conducted. Population 20,000. Four other resident Practitioners. Good house, with stabling, &c. Twelve months' introduction if desired. Address X. 238, Mr. Langley, as above.

WITHIN Ten Miles of London, a Partnership in a good Family Practice for Transfer. Receipts from £1200 to £1500 a-year, and capable of considerable increase. The locality is pleasant and easily accessible from London. A first-class residence, with every convenience, at a moderate rent. Terms based upon a two-years' purchase. The successor must be doubly qualified, and not under 35 years of age. Address X. 235, Mr. Langley, as above.

IN a Large Town, an old-established high-class Practice, with valuable honorary appointments, for Transfer. Receipts £800. The Practice is non-dispensing, and capable of great increase. The successor must be a good Obstetric Surgeon. Address X. 231, Mr. Langley, as above.

COUNTRY PRACTICES, with appointments.—Mr. Langley has several eligible openings of this kind, suitable for young Professional Men with limited capital at their disposal. Apply as above.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FIRST OR PRIMARY PROFESSIONAL EXAMINATION FOR THE LICENCE.

THE Next Examination will commence on TUESDAY, April 7. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND OR PASS EXAMINATION FOR THE LICENCE.

The Next Examination will commence on TUESDAY, April 14. Gentlemen who have completed four years of Professional Study, according to the College Regulations, are eligible for admission to this Examination.

Registered Medical Practitioners, qualified before January, 1861, are admitted to Examination under special by-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the By-laws are to be left at the same time.

Pall-mall East, 1868. H. A. PITMAN, M.D., Registrar.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE Council have the pleasure to announce that the Right Hon. the Earl GRANVILLE, K.G., President of the College, has kindly consented to take the Chair at the FIFTEENTH FESTIVAL of the College, which will be held at Willis's Rooms, King-street, St James's, on Wednesday, the 13th of May next. Dinner at half-past six o'clock.

Gentlemen who are willing to serve as Stewards on the occasion are requested to send their names to the Secretary, at the Office of the College in Soho-square. No pecuniary liability is incurred by the Stewards.

By Order of the Council,
ROBERT FREEMAN, Secretary.

37, Soho-square, London, March 18, 1868.

THE LONDON SURGICAL HOME,

FOR Diseases and Accidents of Women; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. BAKER BROWN.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the LADY SUPERINTENDENT, 18, Stanley-terrace, Notting-hill, London, W.; or to Mr. BAKER BROWN, 136, Harley-street, London, W.

30th November, 1867.

LONDON NURSES' INSTITUTE,

42, South Audley-street, Grosvenor-square, W.

TRAINED NURSES (Medical, Surgical, Mental, and Monthly), can at all times be obtained from this Institute.

Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended.

Apply to the Manager or Matron. T. HAMILTON, Manager.

OMAGH DISPENSARY DISTRICT.

OMAGH UNION.

THE COMMITTEE of the above DISPENSARY DISTRICT will, at their meeting to be held in their Committee Room, Omagh, at one o'clock, on SATURDAY, 28th March instant, proceed to elect a properly qualified person as MIDWIFE for the Western Division of the above District, at a salary of £20 per annum.

Applications, accompanied by certificates of competency, to be lodged with me one hour before time of meeting. Personal attendance of candidates indispensable.

By order,
A. RODGERS,
March 9, 1868. Hon. Sec. of Committee.

LURGAN UNION.

MEDICAL OFFICER WANTED FOR THE MOYNTAGH SUB-DISTRICT OF THE LURGAN POOR-LAW UNION.

THE Committee of Management of the LURGAN DISPENSARY DISTRICT will, at a Meeting to be held in the DISPENSARY, LURGAN, at Three o'clock, on THURSDAY, the 9th day of APRIL, elect a properly qualified Candidate to the above appointment.

Salary (exclusive of Vaccination and Registration Fees) £100 per annum.

Residence in the Sub-District indispensable.

Papers and Testimonials to be lodged with me before ten o'clock on the morning of the Election, and Candidates must be in attendance.

By order,
JOHN HANCOCK, Hon. Sec.

The Manor House, Lurgan,
County Armagh, 12th March, 1868.

THE

ORIGINAL CHLORODYNE,

INVENTED BY RICHARD FREEMAN, PHARMACEUTIST.

Is largely employed by the most eminent Physicians and Surgeons in Hospital and Private Practice in all parts of the world. It produces therapeutic effects which are peculiarly its own, and which are not approached by any of the various known or secret compounds made in imitation of it, and called Chlorodyne. Sold by all Wholesale Druggists, in bottles, 2 oz. 2s. 9d., 4 oz. 4s. 6d., 10 oz. 11s., 20 oz. 20s. Discount to Profession for cash, 20 per cent.

70, Kennington Park-road, London, S.

FINEST IMPORTATIONS, 1867.

LIGHT BROWN COD-LIVER OIL.

(including tin), 6s. 6d. per gallon.

PALE NEWFOUNDLAND FINEST

(including tin), 9s. 6d. per gallon.

Remittance to accompany order. P.O.O. made payable at the Chief Office.

T. Keating, 79, St. Paul's-churchyard, London, E.C.

BEWLEY, HAMILTON & Co.'s

COD-LIVER OIL OF 1868.

This Oil, as originally prepared by them in 1850, and since then yearly, with the increasing approbation of the profession, and of those numerous Invalids who have derived such inestimable benefits from its use, is extracted from the fresh Livers of the Channel Cods, on B. and H.'s own Premises, and under their immediate superintendence, and is possessed of the properties of this valuable Medicine in an eminent degree.

Sold in Pints, Half-Pints, and Quarter Pints, in Bottles, secured by their Stamps, by

BEWLEY, HAMILTON, AND CO.,
(Late Bewley and Evans),
STATE APOTHECARIES,
3 AND 4, LOWER SACKVILLE-STREET, DUBLIN.

NOTICE.—BEST QUALITY ONLY.—SAMPLES FREE.

ISLINGTON GLASS BOTTLE COMPANY WORKS, LONDON and YORKSHIRE. This Company supply only the very best MEDICAL GLASS BOTTLES and PHIALS, at the Lowest Prices. London Warehouses, 19, Bread-street-hill, Upper Thames-street, City, E.C., and 28, Copenhagen-street, Islington. E. & H. HARRIS and CO., Proprietors.

		per gross.

CLINICAL REPORTS.

By EDWARD HAMILTON,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

REMARKABLE TUMOUR AT THE BASE OF THE TONGUE.

A FEMALE, aged 20, presented a peculiar morbid growth on the dorsum of the tongue. It was lobulated, and had the translucid appearance so often exhibited by gelatinous polypus of the nose. It impeded deglutition and speech, but caused no pain, and was chiefly troublesome from a feeling of discomfort, and a constant desire to swallow. The mass was easily exposed to view by depressing the tongue, and appeared pedunculated, situated in front of the left glosso epiglottic fold, and suggested the idea of a circumvallate papilla, immensely hypertrophied. She stated that she perceived it about six months before, but that within the last month its growth was most rapid. Its removal was easily effected by the ordinary chain ecraseur.

UNUNITED FRACTURE OF THE FEMUR, TREATED BY BICKERSTETH'S METHOD.

M. C., a strong and well-developed man, about 40 years of age, eleven months previous to his admission sustained a fracture of the left femur at the junction of its middle and lower third. For this he had been treated with the long splint during six weeks, the starch apparatus being then applied for a fortnight. Subsequently the limb was a second time placed in splints, and then in gypsum. On admission there was very distinct mobility at the seat of fracture, the femur bending at an angle, and yet by a vigorous muscular effort he was able to raise the limb from the bed, but it was totally useless for the purposes of progression; on examination there was found to be great over-lapping of the ends of the bone, the lower extremity of the upper fragment projecting backwards considerably and approaching the skin. The limb was fully one inch and a-half shorter than the sound one.

An incision was made from behind, down to the surface of the upper portion, and the drill applied until this was perforated, and then pushed forward until its point was felt against the lower fragment, into which it was worked; as soon as it had fairly entered, and the rotation of the drill became impeded, the stock was removed, leaving the drill as a peg, pinning the ends of the bone together, transfixing the posterior, and impacted in the anterior fragment.

The limb was invested with layers of cork carpet, which I find a most convenient and manageable appliance in the treatment of many cases of fracture, holes being cut to admit of the escape of the free end of the drill, also permitting discharge to come freely through, and was laid on an inclined plane. No disturbance, local or constitutional, followed the operation, a trifling amount of suppuration flowed from the opening, but caused no trouble; in 25 days the drill dropped out, and in two months he left the hospital with the fracture firmly consolidated.

DISLOCATION OF THE HEAD OF THE FEMUR ON THE DORSUM OF THE ILIUM REDUCED BY MANIPULATION.

A labourer, æt. 45, presented all the symptoms and appearances of dislocation of the head of the left femur upwards and backwards. A week previous to his admission he was severely injured by the falling of a bank in a quarry, where he was working. Some attempts were made at reduction previous to his admission, but the deformity was still distinctly characteristic of the dislocation. As he lay in bed *without chloroform*, the ankle was grasped by the left hand, and the knee by the right, the thigh was flexed on the abdomen, as far as possible, to the right side, then abducted and everted. On the second trial the head of the bone was felt to enter the acetabulum, and the limb restored to its natural shape and movement. He left the hospital in a week, having perfect use of the leg. Some time ago Dr. Wharton and I brought under notice of the Surgical Society of Ireland cases which proved the value of this method proposed by Dr. Reed, and I am convinced that were it more generally known, and practised immediately on the occurrence of the accident, it would be attended with the most marked success.

CONTRACTION OF THE ORIFICE OF THE URETHRA, OPERATION BY COLLES' METHOD.

R. E., 39 years of age, contracted gonorrhœa about two years ago. There was at the time much pain at the end of the urethra, with occasional discharge of blood, and soreness. After the subsidence of the disease, a thickening was felt on the under surface of the urethra at the orifice, and gradual increasing constriction followed. The opening will now barely admit an

ordinary probe. Micturition is very slowly accomplished, and a part of the urine remaining in the urethra and dribbling away, causes him increasing annoyance and discomfort; having frequently observed how little this special form of stricture is amenable to the ordinary modes of treatment, the following operation was practised:—A fine director was introduced into the urethra, and its lower wall divided for about three quarters of an inch, the cut surface on each side was then scooped by dissecting away a portion of the corpus spongiosum with a curved scissors, the edges of each surface were thus easily approximated, and retained by sutures of horse-hair. Cold was constantly applied, and small doses of tartar emetic administered with a view to guard against erection.

The horse-hair suture is especially adapted for operations in this situation, as it will not corrode like wire, nor soak the urine like silk; it must be introduced a good distance from the edge, or it may cut out too soon.

REMOVAL OF THE BREAST—EMPLOYMENT OF TORSION.

B. K., married, aged 34, has had two children; presented a florid complexion, and very healthy aspect; she complained of a tumour in the right breast of three months' duration; the nipple was retracted, hard, and wart-like; the surface of the skin for some distance was thickened, and of a dusky hue; she complained of occasional lancinating pain; there was no enlargement of the axillary glands; the case thus seemed a most favourable one for operation, which was accordingly performed in the usual way, removing a large segment of skin; the vessels, which were numerous and large, were caught and twisted with Syme's torsion forceps, an instrument which I had an opportunity of seeing, through the kindness of Professor Tyrrell, of the Mater Misericordiæ Hospital. In all the operations recently performed at Steevens' Hospital, this mode of arresting bleeding has been exclusively adopted; even in a case of amputation of the thigh last week, by Mr. Colles, the femoral trunk was the only vessel secured by ligature, all the others were sealed in the most expeditious and efficient manner by torsion, and in no single instance has there been the least appearance of secondary hæmorrhage. No pocket-case should be without this instrument, as almost superseding the ligature in the treatment of bleeding from recent wounds. The wound was sponged with chloride of zinc, after the plan of M. De Morgan, using a weak solution, a practice which my experience leads me to regard most favourably: it arrests the weeping from small blood-vessels, cleanses the wound from clots, and produces an instantaneous glaze, very conducive to immediate union; the tumour, on examination, presented all the characters of schirrhus cancer.

ON VIVISECTION.

By HENRY MAC CORMAC, M.D.,
CONSULTING-PHYSICIAN TO THE BELFAST HOSPITAL.

ANY needless or avoidable severity, in respect of the lower races, is an inexcusable abuse of the power which has been lent to us. In some it seems to spring from want of thought, in others from the absence of both thought and feeling. The brute is treated as if stripes and blows made no impression upon him. At the butcher's, one hardly sees a carcase that is not disfigured by weals, and yet increased commiseration for animals would seem one of the characteristics of the times. Cruelty to the brute is a direct infringement of the law of God, and cannot be indulged in without injury to our better nature. Humanity to animals should be a public charge; paid inspectors ought to be appointed by the State. The butchering business should be alone confided to competent well conducted persons, and every reasonable precaution taken to check the tendency to abuse. The doings reported at the veterinary school at Alfort, are simply infamous. Every desirable result might be accomplished, and with comparative immunity from suffering. Animals recently slaughtered, I submit, should alone be operated upon, and anæsthetics resorted to, so as to ensure a painless death, or, at any rate, the insensibility which for the time excludes all appreciable suffering.[1]

Making every reasonable concession, vivisection has not, I opine, been productive of the many and great advantages which have been claimed for it. In certain instances it is just possible that operations performed on the brute might serve to lessen the risk and suffering incurred by the man. Some, indeed, would justify vivisection on the plea of veterinary education. Anatomical and physiological knowledge is needful in equine as in human pathology, but neither one nor the other need involve the cutting up of brutes alive. Hippopathology does not demand this cruel alternative any more than does human pathology. What, for example, has vivisection to do with the successful treatment of cattle plague? and yet it has been absurdly urged as subservient. "If veterinary surgeons," exclaims M. Diday, "cannot be made in two years without vivisection, in mercy's name let them have four, and so spare the hapless brute. To torture animals is but an apology for ignorance, and to the properly instructed pupil, surely vivisection is superfluous."

Vivisection did not determine the uses of opium, quinine, antimony, ether, or chloroform, or those of the freezing mixture or ether spray. It did not enable Fabricius to notice the valves of the veins, and thence conduct his pupil Harvey to the brilliant induction of the major circulation, which, as Harvey himself remarked, could not as thus be otherwise. Hence, as Gerdy in his Account observes, this greatest of physiological discoveries was due in the first instance to reasoning and observation alone. It was not, indeed, vivisection that proclaimed the prophylactic efficacy of matter from the cow. Nor was it vivisection that led me to the immense deduction, as I hold it, that tubercle is no other than the unoxidised residue of the interstitial carbonaceous waste, thus enabling us, as I assume to have proved, to stamp out consumption and scrofula when we will.[2]

Precious as are the discoveries in physiology, we are bound to compass them with as little animal suffering as possible. Some forty and odd years since, aided, indeed, by vivisections, Bell announced, and Magendie, himself a great offender, confirmed, that of nerves issuing from the spinal marrow, the anterior controlled motion mainly, the posterior mainly sensation. Magendie showed that the motor nerves, owing to the presence of minute fibres of the nerves of sensation, were also sensitive. This Longet, after 330 experimental trials, denied; while Magendie, singularly enough, became himself no longer able to detect it. Here, however, Claude Bernard stepped in, and showed that when the dogs and cats whose spinal marrows had been laid open were allowed, unhappy creatures, to recruit and rest a little, the sensibility in question became plainly apparent.

A complete revolution, Brown-Séquard affirms, has accrued in medicine from the study of physiology as based on vivisection. Among others, he adduces a case of paralysis of motion from the neck down on the right side, coupled with extreme sensitiveness, a rise in temperature, and a more rapid circulation. Sensibility was abolished on the left side, but the power of motion subject to the will remained intact. Here there had ensued transversal division of the right lateral half of the spinal cord, inclusive of the posterior and lateral columns in the neck. As the nerves of voluntary motion on the right side pass along the right side, and those of the left side on the left, the division of the spinal cord as described produced loss of motion on the right side only. But as the nerves of sensation pass to the opposite side, loss of sensation on that side, the cord being divided as stated, was the result. When the medulla oblongata is subjected to pressure from

1 The Painless Extinction of Life in Animals designed for Human Food. London: Longmans & Co. 1864.

2 Consumption, as engendered by re-breathed air, and consequent arrest of the unconsumed carbonaceous waste. 2nd ed. London: Longmans, Green, and Co. 1865.

some morbid growth or tumour on a level with the decussation of the anterior pyramids—say on the right side—it would affect the fibres of voluntary motion before they decussate, as well as those from the left side, which have already decussated, inducing paralysis on both sides, but leaving the blood-supply and lesions of sensibility as before. Injury of the pons varolii implicating the trigeminal, facial, and sixth pair before decussation, also induces paralysis on the injured side. Caries of the petrous bone at the base of the brain, with other forms of local disease, leads to paralysis. There is also reflex paraplegia, owing to reflex irritation, implicating the fifth pair and otherwise. Here, however, Brown-Séquard admits obscurity and contradiction, so that, taking everything into consideration, vivisection, motives of humanity aside, does not seem superior, in respect of imparting information, to ordinary observation. Indeed, Brown-Séquard speaks of having divided the par vagum, and of crushing the ganglions of the sympathetic in the abdomen, with no other result than occasional derangement of the heart's action. Was this, then, sufficient to justify such operations, or would the heart's action of any living creature remain as thus underanged ?

But other procedures entailing hardly less suffering have also been had recourse to. Thus strychnine which induces violent spasms, and curara, paralysis of the muscles, have been exhibited. The latter substance may be swallowed with impunity, but oxen when wounded with arrows dipped in it die, unless artificial respiration be maintained, in about 20 minutes. The Indians who know nothing about this, resign themselves, Humboldt tells us, as to inevitable death when the curara or woorara gets into their blood. The heart continues to beat even after the muscles of voluntary and semivoluntary motion have been paralysed by this death dealing substance. But the heart's action, it has been ascertained, itself ceases through the yet more fatal influence of the cyanide of potassium.

On the whole, then, vivisection, whether with the knife or, if I may be allowed the expression, with other destructive agencies, has not shed that perfect light on the functions, whether in health or disease, which was at one time so sanguinely anticipated. If indeed the practice must be continued let it at least be restricted to men of science and education, and not delegated to bunglers and beginners as at Alfort, where unhappy brutes have been mangled for hours. Vivisection in fact has too often been undertaken with the vague idea of compassing a quite inaccessible knowledge. A wise ignorance is surely preferable to an unwise pretention. For things there are of which, by the very constitution of our faculties, we must perforce remain ignorant for ever; and it is not by mutilating the wondrous apparatus subservient to animal existence that we shall evade the secret barriers that encompass life and organisation. Structure and function, in animated nature, must be studied as one. How is the disruption of living organs, with the severment of their exquisite and, in truth, indispensable nexus, to yield the knowledge which, so far as it is accessible at all, must be sought for in the observation not of broken but of harmonious function, not of a portion but of the integral whole. We shall never, I am persuaded, light up the arcana of being by mutilation. The conditions of existence will be better appreciated by surveying them in the concrete, than by resorting to procedures which harass our sympathies and hardly satisfy our reason.

There are operations, however, vivisections in all but the name, to which horned cattle, sheep, swine, horses, and even fowl, are subjected with the view, real or illusory, of rendering them better fitted for human requirements, operations conducted without the aid of any anæsthetic, in a fashion so rude and on a scale so extended as to entail greater suffering, were it in a single day, than have done all the vivisections bearing on science since science has had a name. To these operations, as thus conducted, the world with its usual inconsistency hardly if at all adverts. And yet no plea short of necessity justifies the infliction, were it of a single avoidable pang, on creatures which, in respect of their many and in truth exquisite endowments approach and perhaps in some respects excel ourselves. Alas, we are cruel to the lower races as we are cruel to our own kind. In what respect indeed is the deep and deadly laceration of the scourge, with branding, gagging, hanging, and the guillotine, less flagrantly reprehensible than vivisection. In truth we are all too merciless to the beings which surround us, violating thus the divine and never with propriety to be evaded obligation of inflicting no needless pain, no cureless ill.

Some would have us to believe that the inferior races do not feel as we do. Alas, they experience suffering, a little more, a little less, even as we experience it. For pleasure and pain are as janitors at the portals of existence, janitors without whose ceaseless vigilance neither reason nor instinct could keep watch were it for a day. All warm-blooded animals at least, the infliction being applied, experience pain, for pain is among the safeguards of the organism. The little Jew or Musselman boy suffers as much during the barbarous operation of circumcision, as did and do the victims of the other equally brutal mutilation, perpetrated with the view of creating singers in Italy and eunuchs in the east. Who shall sum up the torture inflicted on Chinese women, from the insensate crushing of the tender structures of the foot in infancy, on the women of Europe, by reason of screwing in the chest until the ribs flatten, and the spine lose its tapering symmetry. Animals have been seen to eat, just after torturing operations and cruel accidents, and therefore, says Brown-Séquard and others, do not undergo much if any suffering. But not to dwell on the endurance of American Indian, who have been known to sing and declaim under tortures and of Hindoo widows who lie down to be burnt alive, I have known men to converse calmly and even smoke during the removal of a limb. I was close by when Dupuytren operated on a little boy for the stone. The child had been promised some present if he abstained, and, I remember, evinced such fortitude, as never once to utter a cry or a moan. Will any one, therefore, in such instances, allege that there is no suffering. Ah ! there are things about vivisection that cannot be committed to paper, the agonising, if inarticulate intreating, the groans, the pantings, and the cries, the paws even of poor brutes being cast round the neck of the hardened operator. The dog, which ordinarily or even extraordinarily, never sweats, does so, it has been stated, profusely, under the vivisector's knife.

Animals during the process of their conversion into food, are deprived of life with almost every painful and barbarous accompaniment, not in Britain only, but wherever the employment of their flesh for nourishment extends. And yet, so long as consciousness subsists, the slaughtering process is a vivisection in everything but the name. Throats are cut, the poor brutes are stabbed, their skulls, ah, me, are driven in, with what anguish, who can say, as life ebbs slowly, all too slowly away. The manner in which cast and worn-out horses are treated in knackers-yards in London, and in Paris at Montfaucon, is difficult or impossible to realise. A thousand forms of nameless and unspeakable cruelty, indeed, flash upon my recollection and call, if only I could supply time and space, for mention. A few years since infamous wretches used to prowl about London streets, entrapping and skinning cats alive, which they then left to stagger about till they expired. Birds, rabbits, hares, are mangled by thousands, to pamper a cruel and unwholesome vanity. Even wild animals are followed and needlessly slaughtered in the waste. For years calves taken from green pastures and pent in some filthy cellar, are stuck from time to time by the butcher or his boy, and bled till they fall upon the gory floor, in order to gratify, by a factitious and superfluous whiteness the palate of persons who, perhaps, during the very repast, take occasion to descant on the cruelty of vivisectors.

And yet animals, as I have shown, may be deprived of life by a procedure at once so painless and effective as, I submit, to do away with every plea for the infliction of

needless suffering. This procedure is no other than the substitution of an anæsthetic, say carbonic acid gas, for the ordinary atmosphere. As this gas is wholly irrespirable, animals immersed in it become at once insensible, so as to permit the butcher's functions to be discharged without the infliction of a pang. I purposely visited the slaughtering-houses at Islington, and tried to talk over the functionaries there. You will have a deal of trouble, said one honest fellow, before you are able to work any change. The easiest way, observed Mr. Grimaldi, the head butcher, to kill an ox is to knock him on the head. He does not feel it. I can hardly admit that, Mr. Grimaldi, I rejoined. And farther, the pole-axe, were it even painless, is not resorted to in the instance of lambs, sheep, swine, calves, and fowl. In fact, the rich and well-to-do are in complicity in respect of the cruelties incident to the butcher's calling. They are the great meat-consumers, and, if they would, could at once put down killing practices, whose barbarous severity leaves all that has been alleged of vivisection quite in the shade. Surely no torture, no avoidable infliction, whether brief or protracted, ought to be tolerated towards creatures which, by their warm affections, their grace and beauty, make appeals to the heart and understanding, only less impressive than do similar qualities in ourselves. Butchers should be constrained to the adoption of painless modes of slaughter. Animals ought not to be put to death in towns but in the country, and that by persons who had nothing to do with the sale of their flesh, with all possible cleanliness, decency, and despatch. It is repulsive to see kennels reeking with gore, the soil strewn with convulsed frames and vitals yet warm and quivering. It racks the heart to listen to the plaints of God's sentient creatures undergoing inflictions cruel as they are superfluous. Though bereft of articulate utterance, still by signs and tokens which no one can affect to misinterpret, they give expression to their suffering. The moral sense is outraged, purity is violated, and the public health is endangered. And yet, man by nature is not necessarily savage or vindictive. Would we approve our affinity with a most divine Creator, let us do so by a greater compassionateness to the beings, placed for a time at our disposal, beings which, in their God given endowments, approach us more nearly than as yet, alas, we do Him.

CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE OCCURRING IN THE EIGHTH MONTH OF PREGNANCY.

By GEORGE EDWARD CARRE, M.B.T.C.D.

Mrs. H., the wife of a comfortable farmer, pregnant of her fifth child, was disturbed about half-past twelve o'clock on the morning of the 19th of January by one of her children who was threatened with croup. She got up, gave him some medicine, and returned to bed, feeling quite well.

Very shortly after this she felt pain in her bowels, and got up to the night-chair, while there she became faint, and had to call to her husband to get her some water; in a few minutes she got better, and returned to bed.

The pain and faintness came on again in half an hour—the pain being now constant; she was very restless, and could not lie quiet for any length of time; faintness followed by sickness of stomach coming on every time she moved; she continued in this state until one P.M., when I was sent for.

I found her in bed with her head and shoulders raised; her face pale; lips blanched; feet and legs cold; pulse 86, but very feeble; complaining very much of weakness, sickness of stomach, and a constant gnawing pain like that of labour all over the abdomen, and shooting down her thighs; the weakness and sickness of stomach she attributed to some weight pressing on her stomach, and pushing it up towards her heart, and was most urgent that something should be given to relieve the pain and weight.

There was some tenderness over the stomach; none whatever over the uterine tumour, nor did it feel larger or more tense than is usual in the eighth month.

I found the os uteri very high up, quite small and closed; the fœtal head could with difficulty (owing to the womb being so high up) be felt through the cervix; there was no clot lying between the cervix and membranes, nor was there the slightest symptom of labour having set in, though she was most positive that the pain (though constant) was that of labour. She now became very faint, and complained so much of pain in her abdomen that I gave her thirty drops of tinct. opii in some whiskey; had hot jars applied to her feet; a mustard poultice to her stomach; after some little time she rallied. I ordered her a tablespoonful of brandy every half hour, and small pieces of ice to be placed in her mouth; nothing seemed to relieve her until about half-past two o'clock P.M. (more than twelve hours from the time that the pain and faintness commenced), when, while turning in bed, there was a great gush from the vagina; she at once called out, the weight is off my stomach, I am a great deal better. On examining, we found the bed saturated with blood. I at once made an examination, and found the os very slightly dilated, so that I could get the point of my index finger in; the membranes were not at all tense, and the head could easily be felt; while I was examining there was another gush of blood. I now ruptured the membranes, and let off a very large quantity of liquor amnii, not in the slightest degree tinged with blood; the hæmorrhage ceased at once; I gave her some brandy, which now remained on her stomach. Her pulse was very weak, though she said she felt stronger, and could turn without faintness coming on; regular labour pains set in, and at half-past three o'clock she was delivered of a still-born child.

On placing my hand over the uterus I was at once struck by its large size, and thought there was another child in utero, but on making steady pressure for a minute or two, the placenta came away, followed by three or four clots of blood, two of them as large as the placenta; she became very weak, but after I had given her some brandy, and applied the bandage, she rallied; her pulse was now so weak I could not feel it at all in the right arm, very indistinctly in the left.

There was some slight draining, which was stopped by infusion of ergot.

Having given strict orders that she should be kept perfectly quiet, and get a dessert spoonful of brandy every half-hour, I left.

Ten o'clock P.M.—She feels much better; has had no return of the faintness; pulse stronger; passed catheter, and turned her on right side; to get a dessert spoonful of brandy every second hour.

January 20.—Had two or three hours refreshing sleep during the night, and feels much better; complains much of pain in her head, and noise in her ears; pulse 100, very weak; she passed water shortly before I saw her, and did not get weak when the nurse turned her; to get a dessert spoonful of brandy every three hours; fifteen drops of spt. ammon. aromatic three times a-day; room to be kept dark and perfectly quiet.

21st.—Going on very well; continue brandy; vinegar and water to breasts; enema to be given early to-morrow morning.

22nd.—Bowels moved; pulse 86; colour returning to lips and cheeks; to get brandy and chicken-broth.

26th.—Still improving; appetite good. She made a steady recovery from this, and was able to sit up on the twelfth day for a short time.

I think the above case is interesting for several reasons—*firstly*, the separation of the placenta without any strain or over-exertion; *secondly*, the length of time that elapsed between the commencement of pain and faintness and the appearance of blood externally; and, *lastly*, the relief which the poor woman felt as soon as the blood flowed externally, thus relieving her from the feeling of weight and pressure which were so distressing to her, and which were no doubt caused by the blood's accumulating between the uterus and decidua, becoming as it were encysted.

A CASE OF CHOLERAIC DIARRHŒA, WHICH HAD RESISTED OTHER TREATMENT, CHECKED BY THE APPLICATION OF CHAPMAN'S ICE-BAG.

By H. FITZGIBBON, M.B., M.Ch.

THE following case of diarrhœa occurred with some others in the early part of January last, on board the West Indian steamship "St. Thomas," at New Orleans. It seems to me interesting, as supporting Dr. Chapman's statement, that cases of diarrhœa which resist the usual treatment, and even threaten to terminate fatally, as cholera, may be subdued by the application of an ice-bag along the spine.

There had been no diarrhœa or cholera up to the time of the ship's arrival at New Orleans; but there, owing to the use of Mississippi water by the crew for cooking and drinking purposes, eight of the men were attacked with severe diarrhœa. They all recovered under ordinary treatment, by astringents, opium, &c., except the chief cook, George Alphonso St. Cire. This man came to me on the morning of the 7th of January, stating that he had been purged during the previous night thirteen or fourteen times, he complained of great weakness and a sensation of dizziness. His tongue was clean, his pulse 75 in the minute, but very weak. I gave him three grains of acetate of lead, and half a grain of opium every fourth hour during the day, also a little brandy. The diarrhœa was checked under this treatment from about two P.M. until after he turned in at eight P.M.; he, however, had a return of it shortly after he went to bed, which continued until the following evening, when I gave him a dose of castor-oil, and the following mixture:—℞ decocti hematoxyli ad. ℥viii.; pulv. cretæ comp. gr.120; tr. catechu ℥iii.; tr. opii ℥i.; ℿ sumat ℥i. 3tiis. horis.

The diarrhœa was mitigated while he was on this treatment, but he continued more or less to complain of weakness, faintness, and disinclination for food, in fact he would eat nothing but rice, and but very little of that.

On the 20th of January he gave up attempting to do his duty, which, up to this, he had persisted in. I now found him purging every half-hour, the discharges watery, dark-coloured, and extremely fœtid; his pulse 90, and very weak. He complained much of dizziness, sickness, and weakness; he also complained of cramps in his legs, and abdominal gripings. There was no tympanitis nor pain upon pressure, but some borborgyrm over the ascending colon. I now gave him a large enema of warm water, which was immediately discharged; I then got him again into bed, had his feet rolled up in warm blankets, and applied Chapman's large ice-bag, filled with pounded ice, along the whole length of the spine, and retained it in position for twenty minutes, this was at 8 P.M. There was no return of the purging between this and 12 P.M., when I again applied the ice in the same manner. Next morning when I went to see him I found him sitting up, much pleased at having had an uninterrupted night's rest, he, however, complained yet of weakness and lightness in the head, but had no return of the purging whatever. There was no recurrence of it after this, and his appetite and strength improved, so that in three days he said he was quite well, but a little weak; his bowels, however, had not been moved at all, so that I gave him some castor-oil, after which they acted naturally.

That astringents or opium would not stop the diarrhœa in this case I am convinced, and that it was checked either by the ice-bag or the warm water enema, or both combined, I am certain, but I am inclined to give all the credit to the ice, as I do not think it could have been dependent upon any irritating matter actually in the intestines, as anything of that kind would probably have been removed by the castor-oil administered on the 9th inst., after which he never used any water except that condensed from the ship's boilers, which must have been perfectly pure.

Hospital Reports.

THE LONDON HOSPITAL.

CASE OF DOUBLE HYDROCELE, CURED BY INJECTION.

Under the care of T. B. CURLING, F.R.S.

(Reported by Mr. VIALLS).

WM. P., æt. 64, was admitted into the London Hospital, December 3rd, 1867, suffering from a double vaginal hydrocele, the right one being considerably larger than the left. The right one was transparent, showing the testicle at its posterior and upper part. The left was perfectly opaque, and had existed for eight years. The larger one had existed only two months.

December 11th.—Mr. Curling, after drawing off the fluid by means of a trochar, injected both sacs with a strong solution of iodine, leaving about ℥ii. in each sac. The fluid drawn off from the larger and recent hydrocele was transparent, of a straw colour, and measured about twelve ounces; that from the smaller one measured about six ounces, was thick and opaque, and had floating in it a large quantity of cholesterine.

After the operation the patient walked to his ward, having suffered very little from the injections.

12th.—The scrotum is supported by a crutch-pad; parts very tender but not much swollen; does not feel ill; pulse 96; temperature normal.

13th.—Both testicles tender, the left a little swollen.

14th.—Complains of pain on both sides of scrotum, and slightly feverish.

16th.—Less pain about the parts, but a little effusion in each sac.

20th.—Gradually improving; has very little pain.

24th.—Feels quite well, but has still a little effusion in each sac; is allowed to get up.

31st.—The effusion has not quite disappeared; tinct. iodinii to be painted upon the scrotum every other day.

January 3rd.—To continue treatment.

8th.—The right sac is empty, but the left still contains some fluid.

10th.—Discharged; to wear a suspender. The right side is quite cured, but the left still swollen and thick.

In the course of some clinical remarks upon this case Mr. Curling said that he had brought it under the special notice of his pupils, not only in order to illustrate the treatment of double hydrocele, but because it afforded them the opportunity of seeing the effects of treatment by iodine injections in two stages of the disease—in recent and in old hydrocele. The hydrocele on the right side was recent (of only two months' standing) and easily recognised by its transparency; while the hydrocele on the left side, though smaller than the other, was old (of eight years' standing), and perfectly opaque, owing to the sac being thickened and the fluid turbid. This hydrocele contained, as it often does in old hydrocele of persons advanced in life, a large quantity of cholesterine.

The opinion formerly was pretty general that in double hydrocele injection should not be performed on both sides at the same time, as the effects of the double operation might prove very severe, and that injection on one side has been known to cure both, by the extension of the inflammation from one sac to the other. These objections might hold good formerly when very irritating fluids were injected, and active inflammation induced, but Mr. Curling had never known the injection of one sac with iodine cure double hydrocele, and the effects of iodine injections are so mild, that no objection can exist to both hydroceles being operated on at the same time. In late years he had frequently injected both sacs at the same time, and had cured double hydrocele without more irritation and trouble than in the single operation.

In the case under consideration, injections caused less pain than usual. The recent hydrocele on the right side was readily cured, the fluid consequent on the injection having quite disappeared in three weeks. In the old hydrocele on

the left side the progress of the cure, as was to be expected, was not so rapid. The thickened sac still contained fluid when the patient was discharged, though the swelling was steadily diminishing, and there was every prospect of a satisfactory cure.

ST. MARY'S HOSPITAL.

CASES OF MELANCHOLIA.

Under the care of Dr. BROADBENT,

SENIOR ASSISTANT-PHYSICIAN TO THE HOSPITAL.

LOUISA H——, æt. 52, first came under observation on Feb. 1st, 1866. She had enjoyed good health, except that in the previous winter she had for a short time suffered from symptoms similar to those now complained of. She had had several children, and the catamenia had ceased eight years before.

For some time nervousness had been gradually coming on, and now she was constantly oppressed by great fear. She often trembled with terror, and was apprehensive of sudden death. She could not sleep, and would wander about the house at night, being at times, as stated by her daughter, not only restless, but excited, and even violent. She complained of constant pain all down the spine, in the hips, and at the back of the head. No appetite; bowels confined; tongue furred.

Her manner was absent, her expression rather sullen. She answered questions clearly, but spoke little, leaving her daughter, who accompanied her, to describe her condition. Her face was flushed; there was considerable redness about alæ nasi, and thick acné on chin.

The bowels were relieved by blue-pill and colocynth, and she had in succession mist. quinæ, ammonia, and valerian, and strychnine with iron. Opium was also given at night, but without inducing sleep.

On Feb. 22nd, as she was no better, morphia was prescribed, and continued in gradually increasing doses for three weeks, the daily amount taken during the last week being three grains. The pil. hydrarg. c. colocynth was taken when the bowels became confined; and

On March 8th bromide of potassium was given in doses of twenty grains three times a-day, with spirit of ammonia in infusion of calumba.

After the 15th the morphia was dropped, as it failed to induce sleep; and

On the 22nd the dose of bromide was increased to forty grains three times a-day.

29th.—Had been better for two or three days, attributed to her having been out with friends.

April 5.—Decidedly better; more herself, but still very nervous, and has pain in head and back; face flushed.

The improvement continued till the 26th, when, after being without medicine for a week, the symptoms returned.

It was resumed, and for a few days she was better again; but

On May 3rd was almost as bad as ever. She was, further, getting pale and thin, refused to eat, saying everything was tasteless; her hand also shook. The bromide discontinued. Tinct. valerian and tinct. hyoscy. ordered three times a-day in infusion of calumba. A pill of morphia and conium, to be taken at night, was vomited, and not again tried.

7th.—Had rested better, but was very low-spirited, and had been violent.

14th.—Better; and she was now lost sight of for a time at the hospital, but was met in the street quite herself.

July 26.—Again applied at the hospital as ill as ever; sleepless, nervous, often in a state of absolute terror. Pain across the top of the head; much pain between the shoulders; bowels confined; tongue large, moist, slightly furred. Less acné than when previously seen.

She was ordered to take small doses of blue pill, with taraxacum and colocynth morning and evening. Citrate of potash 30 grs., with spirit of ammonia and infusion of columba, three times a day. A hot-water bag to be applied to the cervical spine in the evening.

Aug. 2.—Worse than ever; very violent at times; head very hot; no sleep. To continue the pills and take bromide of potassium in doses of 30 grains, three times a day.

Aug. 20.—Better at times; still much in the same state; bowels confined; no appetite. Thinks the medicine does her good.

30th.—Better for a week after the last visit—then without medicine for a few days and worse again. The acné very bad. Dose of bromide increased to 40 grs.

Sept. 20.—Quite herself again, but all her limbs weak. In the interval she had had a slight transient attack of diarrhœa, and a profuse vaginal discharge of bright yellow colour, tinged with blood, had come on, and persisted in spite of astringent injections. The bromide of potassium to be taken at night only; ol. morrhua, ʒii. *ter die.* She continued to attend at the hospital till Dec. 10, her spirits good, and her strength returning. At first she could not do without the bromide, but later she took a dose only occasionally when restless after going to bed. She lost altogether the peculiar expression of countenance which had been noted, and was quite cheerful.

Feb. 14, 1867.—Became an out-patient a third time. All the old symptoms back again. At once ordered bromide of potassium, 30 grs. three times a day, and cod liver oil with port wine.

28th.—Sleeping better.

March 11.—No agitation; very weak.

21st.—Bromide discontinued. Mist. quinæ given. Ceased to attend.

April 25.—Cheerful and comfortable.

Aug. 22.—Return of all the symptoms. Treated in the absence of Dr. Broadbent, from town, by aperients and tonics. No better.

Sept. 2.—The patient thinner than when last seen, and less flushed. Pot. bromid. gr. xxx. in infus. columba; ol morrhua, vini. ferri. aa. ʒii.

Sept. 5.—Said to be about the same; expression better.

12th.—Not better. Acné on face worse; spots on chest. Pot. bromid. gr. L., at night only. Oil continued. Calomel and colocynth pill to relieve constipation.

19th.—Sleeps after the mixture; cannot take the oil; the vinum ferri given alone; complains that she has lost the sense of taste.

October 10.—Better and worse since last date; has at times seemed quite well; sleeps well at night; agitated in the day; no taste; bowels much constipated; 1 pil aloes; c sapone gr. x. quotidie.

17th.—Similar report; the mixture to be taken morning as well as evening.

31st.—Better.

November 7th.—Decidedly better; tongue furred in the morning; taste improved; feels when the fauces are touched and retching is induced.

She attended the hospital for the last time on November 21, having in the meantime taken the bromide twice a-day, the vinum ferri and the pills, with an occasional dose of castor-oil, found necessary on account of the great tendency to constipation. The note on this date is "less agitation; more rest; tongue and mucous membrane of mouth sore."

On the 16th December she committed suicide by throwing herself headlong out of a window, fracturing her skull. She was taken to another hospital. The brain was injured; no record of the condition of the abdominal viscera was made.

Case 2.—Louisa C——, æt. 50, married, four children, previously in good health and remarkable for cheerfulness, good flow of spirits and energy, had a slight attack of hemiplegia on the right-side 19 months before she came under the care of Dr. Broadbent. Two days before this attack she had "face-ache" which got well. Then, while ironing the hand suddenly dropped; she did not fall or lose consciousness, and the leg was not at all affected. She was confused for the remainder of the evening, but next morning

was quite clear; she lost her spirits and energy at once; became quite apathetic, and though the arm gradually recovered power she remained in this condition.

The hospital paper giving the date of her first attendance and the treatment first adopted is missing. Her condition on the 22nd July, 1867, is noted as follows:—Spirits very low, agitated, cannot rest in the house, scarcely any rest at night, wakes up in alarm and agitation; countenance expressive of extreme anxiety and distress; bowels only open by means of medicine.

July 29.—Ordered strychnine gr. 1-30th; acid phosph. dil. ℥x. aq. ʒj. *t. d.*; aperient pills as required. This continued till August 29th, when valerian and ammonia were given. On September 9, bromide of potassium was prescribed in doses of 20 grs. three times a-day. Cod liver oil, ʒii.; Pil aloës, c. sapone after dinner.

30th.—Worse. The dose of bromide increased to 40 grs.

Oct. 10.—Worse; no sleep; wakes excited; no peace during the day; cannot sit even to meals; paces about the house; has fits of convulsive crying, one witnessed in the out-patient room; sight dim, memory bad. Quinæ, disulph. gr. v., three times a day. Bromide discontinued. Pills as before.

17th.—Worse than before. She had taken laudanum, first a teaspoonful without effect, then a tablespoonful, after which she was stupid all day, and had some rest at night. She was recommended to enter the hospital as in-patient, and did so, but remained for a few days only, and while there seemed worse rather than better.

In the course of clinical remarks on these cases, Dr. Broadbent pointed out that while the condition of the two patients was at first sight very similar, there were many important points of difference. While they were attending together, he had called attention to the facial expression, in the one sullen, in the other anxious and distressed. The first, when at her worst, seemed indifferent to the questions asked about her, answered only when they were addressed pointedly to her, and then, in a few words, complaining merely of the pains in her head and back, or sometimes of sleeplessness or alarm. Her irritability, agitation, and despondency were known through the account given by her daughter. The attention of the other was concentrated on her condition, and her low spirits and distress were painfully evident.

Dr. Broadbent was inclined to attribute the nervous depression in the first case to gastro-hepatic derangement, indicated by the foul tongue, constipated bowels, and local pains, and he observed that every degree of mental disturbance was met with accompanying disordered function of the different parts of the alimentary canal from temporary lowness of spirits, or irritability of temper, through habitual moroseness or despondency, or hypochondriasis to actual insanity, on which state this patient bordered. The headache, in its heat and character, was such as is often met with from dyspepsia and torpidity of the liver. He attempted, in the first instance, to treat her on this view of the case, but the urgency of the symptoms compelled him to endeavour to relieve or control them by direct action on the nervous system. In the second case the symptoms were clearly traceable to organic injury to the cerebral nervous centres, which gave rise also to the hemiplegia, and it did not seem probable that treatment would be of any great service. Hypodermic injections of morphia, with cod liver oil and tonics, would have given her the best chance, but in out-patient practice this treatment cannot be properly carried out, especially when, as in this instance, the patient lives at a distance (Hackney).

In the first case, bromide of potassium had the effect of inducing sleep, and calming, in some degree, the agitation when opium had failed, a result which Dr. Broadbent had seen in other cases. The repetition of the result, and the aggravation of the symptoms observed two or three times when the medicine was suspended, show that the amelioration was not a mere coincidence. It was to be observed, however, that the good effects were accompanied by great prostration of strength, and Dr. Broadbent had seen this sometimes in cases of epilepsy treated by large doses of this salt. The impairment and perversion of the sense of taste was an interesting fact, and was probably due to the bromide, but the soft palate and fauces, which it has been said are rendered insensible by it, retained their sensibility.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL PRACTICE.

(Continued from page 266.)

Diseases of the Urinary Organs.—Seven cases of irritable bladder were admitted; all were adults. Pus and mucus were found in the urine, and in one a hollow sound detected a rough elevation on the right side of the bladder, but there was no bleeding. Alkalies and anodynes were at first administered; and subsequently, when the water became clearer, and there was less pain during micturition, iron and the mineral acids were substituted, with excellent results.

Five cases of retention of urine were admitted; they were relieved by a warm bath and opium. In one instance the retention was due to the impaction of a stone in the urethra. The urine was drawn off with a catheter; and subsequently lithotrity was performed.

Stone in the bladder presented nine examples; in four of these the lateral operation of lithotomy was performed, and in five lithotrity. One case of lithotomy terminated fatally from suppuration in the kidneys, and one of lithotrity from cystitis.

An interesting case of urethral fistula may be mentioned here, but the details of it have previously been related in our columns by Mr. Ring.

Forty-two cases of organic stricture of the urethra were admitted, fourteen of which were complicated with urinary abscess and fistula. Three died, one of pyæmia, one of suppuration in the kidneys and uræmic poisoning, and one of abscess in the prostate, which produced symptoms closely resembling those of cholera. (This was a most important case, for a detailed account of it see THE MEDICAL PRESS AND CIRCULAR, March 20, 1867, p. 272, as related by Dr. Ogle.) In three cases perinæal section was successfully performed. The remaining thirty-six cases were all treated by gradual dilation of the stricture by means of instruments. Nine cases of enlarged prostate were admitted, in which the disease had altered the normal condition of the urine; one died. By drawing off the water regularly, and in many instances by washing out the bladder with tepid water, these patients were much benefitted.

There were two cases of extravasation of urine in the year. One recovered, and one died. The fatal case was that of a man, aged 48, who had been an in-patient some years ago with some urinary affection, the nature of which the patient could not explain. He had since been in China, and, owing to a recurrence of the symptoms, returned home for medical advice. When admitted, there was considerable redness, swelling, and œdema of the scrotum, perinæum, and lower part of the abdomen. Incisions were made into the scrotum; but on the following day the swelling had increased, and the parts were very foul. The patient was, therefore, placed on the operating table, and the finger was introduced into the rectum, and the prostate found to be enormously enlarged. A bistoury was, therefore, plunged into it, but without effect. An incision was now made in the median line of the perinæum, and a fetid abscess opened. Some more incisions were made into the swollen tissues, and the man was sent to bed. He was in a very low condition, and never rallied, but died on the following morning. The kidneys were large, their secreting structure was diminished in quantity and infiltrated with pus; the calices and ureters were much dilated. The bladder was contracted, its muscular coat enormously hypertrophied, and its inner surface somewhat sacculated. The prostate gland was much enlarged

and indurated; on section, a large abscess was found in its substance with thick walls. There was also another abscess in front of the prostate which communicated with the rectum, and also with one of the incisions in the perinæum, but it did not open into the urethra. In the urethra was a false passage running for about three-quarters of an inch in the submucous tissue, but there was no appearance of any stricture.

Diseases of the Male Organs of Generation.—There were seven cases of primary syphilis occurred, sixteen of secondary; five of gonorrhœa, one complicated with purulent ophthalmia, and four with synovitis; three of phimosis and five of paraphimosis.

Twelve of hydrocele; in eleven of which the ordinary operation for the radical cure was successful. One case resisted repeated and strongly irritating injections, and it was found necessary to lay the tunica vaginalis freely open, and allow it to granulate from the bottom.

One case of hæmatocele was admitted. It was produced two days previously by a kick from a horse. Rest and the application of a cold lotion caused absorption of the effused blood in a week.

Fourteen cases of orchitis were admitted; of these eight were acute and six chronic. The former were frequently due to gonorrhœa, and were treated by rest, a tepid lotion, and the administration of antimony, with calomel and opium; the latter were in three instances due to syphilis, and in two of them there was a fungous protrusion of the testicle; in these instances the red precipitate powder was applied, and the same general treatment pursued as in the other cases, viz.—the administration of cod-liver oil, and syrup of the iodide of iron, or mercury, and the local application of the blue ointment.

Two cases of cancer of the penis were admitted in order that the disease might be removed.

Diseases of the Female Organs of Generation.—Seven cases of abscess of the breast occurred; four of these took place during lactation, and the remaining three originated without assignable cause.

Nine cases of tumour of the breast were admitted. Two of these were cases of sero-cystic disease, in which the disease was removed.

Seven were cases of scirrhus, and in five of these amputation of the breast was performed; in one the disease had been previously removed, and had returned in the cicatrix. Potassa fusa was applied to the wound after the removal of the growth. One case terminated fatally from granular kidneys and fatty heart.

Of the remaining three cases, one was discharged for readmission, and two were incurable; in one of these acetic acid was injected, and found ineffectual. Acetic acid was also injected into an enlarged axillary gland, with the effect of destroying it by suppuration; the mamma was affected with scirrhus, and was removed; the disease returned in the cicatrix, but not in the axilla.

Among diseases of the external organs of generation, we find four cases of abscess of the labium, one of fatty and one of fibro-cellular tumour, with one of epithelioma, all of which were removed; and one case of condylomata.

Six cases of primary syphilis, comprising Hunterian and soft chancres; six cases of gonorrhœa; and sixteen of secondary syphilis, were admitted during the year. One case of vesico-vaginal fistula was admitted, and cured by operation. One case of cancer of the uterus and one of fibrous tumour occurred, but they were discharged, being unfit for operation.

Three cases are classed as polypus of the uterus; in two instances the growth was removed by ligature, in the other the patient was discharged at her own request.

Three cases of ovarian cyst were admitted; two merely for paracentesis, and one with a view to operation. The patient, aged 28, gave the following history. After her confinement some seven years previously, the abdomen commenced swelling, it increased rapidly in size, and paracentesis was performed. This operation had been repeated twenty-six times; the intervals between each had gradually become shorter, latterly being only of a month's duration. The last tapping took place three weeks ago. The abdomen was uniformly enlarged, elastic, and fluctuating in every part, except on the left side, where there was a large firm mass. The os uteri was healthy, and pressed down almost to the outlet of the pelvis; the cervix was short; and the parts around were elastic. The patient had no pain, but felt a sensation of tension of the abdomen; she was considerably emaciated. Over the apex of the left lung there was tubular breathing, with dulness on percussion, and increased vocal resonance. There was no cough. The cyst was tapped, and twenty-seven pints of viscid fluid containing much albumen were drawn off. The mass on the left side of the abdomen could now be distinctly felt; it had firm well-marked edges, and was movable; it appeared to be adherent to another mass occupying the left lumbar and inguinal regions; a third mass was also found in the right iliac region. In three weeks the cyst had refilled; it was tapped, and thirty-two pints of fluid were drawn off. After the relations and connections of these cysts had been attentively considered, the case was deemed unfavourable for operation.

This concludes our abstract of the year's surgical practice at St. George's, condensed from the last volume of reports, and omitting cases which had been related in our columns during the year. On another occasion, we hope to furnish some statistics of the other hospitals.

CITY OF DUBLIN HOSPITAL.

REMOVAL OF AN ENORMOUS TUMOUR FROM THE NECK.

By Mr. CROLY.

We are indebted to Mr. Croly for having had an opportunity of being present at a most interesting operation which he performed on Wednesday, the 11th of March, in the spacious theatre of the hospital, which was filled with medical men and students.

The patient, a woman aged 46 years, presented a most extraordinary appearance, having a huge tumour hanging from the right Parotidean space and side of the neck. It was growing for a period of fourteen years; never caused her actual pain, but was most distressing in consequence of its great weight. It was eight inches in length, and twelve in circumference, oval in shape, and of firm consistence. The patient had been under Mr. Croly's observation for the last three years, however she could not make up her mind to submit to an operation for its removal, but was most anxious it should be done now, having lost a considerable amount of venous blood from the pendent part of the growth a short time before her admission into hospital, which alarmed and weakened her. Being very nervous, she was chloroformed in her bed, and then carried with the "poles and sheet" to the theatre.

The vessels of the neck at the right side having been compressed by an assistant, Mr. Croly commenced by making elliptical incisions through the integument on the tumour near its pedicle, and dissected up the skin flaps. He used the handle of the knife and his fingers alternately, and detached the large mass with rapidity. Several arterial branches of large size were tied with the fine hemp ligature, and the masseteric branch (unusually large) was secured by a large acupressure pin with loop of inelastic wire, according to the fourth method; very little blood was lost. The surface of the wound was sponged with cold water, and then with carbolic acid and oil; the edges of the integument were approximated and kept *in situ*, with American pins and twisted sutures. Carbolic acid ointment spread on lint was next applied, small compresses placed under the jaw, and retained by strips of adhesive plaster. The patient was then removed to her bed.

Mr. Croly made some practical remarks on this highly interesting case. He hoped the tumour, when examined microscopically, would be found to belong to the *benign* class.

He laid great stress on the value of *raising* pendulous tumours (by O'Ferrall's plan) for days previously to operation (which he did in this case with great advantage and comfort to the patient), so as to favour the return of the blood, and also to diminish the calibre of the vessels, thereby lessening the risk of severe and dangerous hæmorrhage during operation.

Mr. Croly also drew the attention of the Pupils to the great necessity of *saving a sufficient amount of integument* to cover the space left by the removal of large tumours.

We are happy to say that on inquiry before going to press, we heard that the patient has progressed most favourably since the operation.

Literature.

RESEARCHES IN OBSTETRICS.

The year before last Messrs A. & C. Black published an important volume,[1] from the pen of Dr. Matthews Duncan, devoted to sterility and the allied topics, which have, as is well-known, occupied for a long time the attention of that distinguished practitioner and teacher of midwifery. That volume comprised twelve papers by the author, that had previously appeared in the "Transactions of the Royal Society of Edinburgh," and in the *Edinburgh Medical Journal*. It included, moreover, an important contribution on "Fecundity and Fertility," by Professor Tait, and a large amount of statistical matter in the form of tables. Altogether, it immediately took its place as a most learned work on the subjects with which it dealt. Were we about to enter into any lengthened criticism of the work, we should feel it necessary to furnish further indications of its contents. As this, however, is not our immediate object, we shall specify only one or two of its more practical and interesting contributions, by way of encouraging practitioners to look into the volume for themselves.

Passing by, then, the chapters on Fertility and Fecundity, we come upon the subject of sterility, which is treated by the author in seven chapters, extending from p. 181 to p. 207. We venture to assert that these chapters comprise the most reliable facts in relation to this obscure subject, brought together in a manner to reflect credit on the compiler, and inspire confidence in his conclusions.

Another very practical section of this work is that devoted to childbed mortality. This is treated in relation to the number of the labour, the age of the women, and other circumstances by which it seems to be affected. The section on the duration of labour will be read with keen interest by those engaged in obstetric practice, and who are constantly asked to predict the day of parturition. Dr. Duncan says, the statistics contained in his volume "will always justify the physician in never giving a decided prognosis of the day of confinement," and a little further he confesses that they show, "that with the most certain knowledge of the termination of the last menstruation, or even of the date of a single coitus, no safe prediction can be made unless within limits so extended as to deprive it of much of its value." Yet even after this qualification, which we think most reasonable, Dr. Duncan adds that "there is no doubt it will always be desirable to know the most probable day of confinement, and this can generally be settled with some exactness." Some of Dr. Duncan's conclusions we will also add. He thinks the interval between conception and parturition, which he calls the real duration of pregnancy, has not yet been ascertained in any case. The average interval between insemination and parturition, which is very commonly called the duration of pregnancy, he puts at 275 days. That between the end of menstruation and parturition he calculates at 278 days. Finally, although he thinks the proofs of prolongation of real pregnancy deficient, he admits that there is evidence to establish the probability that it may be protracted three or four weeks, or even more, beyond its usual limits. Without pretending to have done justice to a book so full of laborious research, we now turn from it to a more recent work by the same author, and which may be looked upon almost as a companion volume to the one we have been considering.

1 Fecundity, Fertility, Sterility, and allied topics. By J. Matthews Duncan, A.M., M.D. Edinburgh: Adam & Charles Black. 1866.

Dr. Matthews Duncan's last work[1] has only been out a few weeks. It is devoted to the subjects which have so long been his favourite studies, and framed on the same plan as his former volume, comprising essays that have already been separably issued in periodical publications.

We shall proceed at once to name some of its principal contents—

Part I. is on the statics of pregnancy, and contains five chapters—viz., 1. The position of the uterus. 2. The natural position of the fœtus in utero in advanced pregnancy. 3. Intenibility of the theories of the position requiring muscular movements. 4. Position of the pregnant female. 5. On the mode of presentation of dead children in labour.

In Part II., the pelvis is studied with a view to obstetrics. We have here chapters on the sacrum, and its use in the development of the lateral expansion of the cavity; on the formation of ricketty pelves, including the author's well-known paper after Meyer of Zurich; on oblique-ovate pelvis, and on the pelvic articulations in parturition.

Part III. consists of nine chapters on various points in the physiology and pathology of pregnancy, and the puerperal state to which we shall presently return.

Part IV. includes various topics in natural and morbid parturition, and may be called contributions to the dynamics of labour.

In one of these eight chapters, we have an essay on the power of the uterus to resist a bursting pressure; in another, an account of the caput succedaneum, and in another, a paper on the production of inverted uterus.

Part V. is composed of three chapters:—1. On the retentive power of the abdomen. 2. On uterine metrology. 3. On vagina duplex and uterus simplex. We have thus given an outline of the contents of this handsomely got up volume which does credit to all concerned in bringing it out; for the publishers have done justice by the author, and had it printed and bound in the best style. The edges only wanted cutting to protect it from the ragged appearance we have imparted to our copy, and which always forms so favourable a nidus for dust.

We now return, as we promised, to the third part on physiology and pathology, and which to our notion is the heart of the book. The first chapter of this part treats of menstruation in early pregnancy. This is followed by a chapter on "Superfœtation," which starts with the theory that as menstruation is an indication that conception is possible, there is no valid reason why this should not hold good when the menses appear during early pregnancy. Dr. Duncan says the "only insurmountable anatomical obstacle is the insertion of the ovum over the os uteri internum, or simultaneously over the internal orifices of both Fallopian tubes;" he appeals to dissections to prove that the uterus "is not closed till some time about the third or fourth month," and he holds that "there is no reason to think superfœtation impossible till this takes place." Further, he calls in evidence instances of so-called twin births, in which one child has been black and the other white, as well as other cases, in which the size of twins has considerably differed. We are scarcely prepared to endorse the author's conclusions, which do not satisfactorily explain how it is that twins developed from a single ovum may differ as considerably in size as those in which two ova have been engaged from the commencement. Nor can we adopt size alone as a proof of age when we see the size of children, by the same parents, born at the full time vary so much.

Still our object here is not to open a controversy, but to point out that while so able an authority as Dr. Matthews Duncan holds the theory it cannot be properly said to be exploded.

Passing over the chapter on the site of the insertion of the ovum, we come upon a very important one on the internal surface of the uterus after delivery, which embraces the author's contribution to the *Medico-Chirurgical Review* of October 1853. He denounces as paradoxical the doctrine which is still very often taught by obstetricians, and appeals to dissection in support of his belief that after delivery the muscular fibres of the uterus are not laid bare, but are covered by a mucous membrane. That such is the case might very well be believed from analogy, but it is better to collect the results of actual anatomical examination. M. Robin has, to some extent, adopted our author's doctrine, as have several English writers, and we think it is likely to gain new adherents; but these writers do not go

1 Researches in Obstetrics. By J. Matthews Duncan, A.M., M.D. Edinburgh: A. and C. Black. 1868.

so far as Dr. Duncan. They seem still possessed of the notion that the entire uterine mucous membrane is deciduous, and that a new membrane is formed beneath it prior to delivery. The notion that the entire internal uterine surface is but a large wound at any time, is utterly repudiated by Dr. Duncan, as is also the idea deduced from it, that the lochial discharge is of a purulent nature. This brings us to the next chapter, in which the author cites the investigations of Wertheimer, founded upon eighteen carefully observed cases.

The sixth chapter of this part relates the history of the mucous membrane of the body of the uterus. The author's headlines to these pages will strike some of the most devout admirers of John Hunter with astonishment, and provoke in many of them a feeling of resentment. He actually uses the phrases "William Hunter's accuracy" and "John Hunter's errors," page after page, with a reiteration that is positively provoking to those who have long looked upon the great anatomist and surgeon with superstitious reverence, and relegated William to an obscure niche in the temple of fame. Modern physiology goes far toward re-establishing the views of William on this point, at the expense of the teachings of his more renowned brother, whose works have exercised an almost unbounded influence on his successors. Whether Dr. Matthews Duncan has proved the doubtful passages of William's work to be the interpolations of the editor, Matthew Baillie, is a question we can afford to leave to literary criticism. Certain it is that Baillie was the posthumous editor, and that some passages, in a style more or less different from the body of the work, do embody John's views, and in so doing are apparently at variance with other portions of the work. Whatever the relative merit of the two brothers, the fame of one has undoubtedly overshadowed that of the other, and is supported by so many other pillars, that the removal of this one could have no influence upon its stability; while that of his brother may be more firmly established by the rectification. Whether this were so or not could, however, have no influence on the justice of the case which demands honour where due, and we are quite willing that William should be, in the language of the day, rehabilitated even though the process be signalized by the paradoxical announcement "William Hunter's accuracy—John Hunter's errors."

Chapter 7, on the length of the cervix in advanced pregnancy, adopts the views commonly attributed to Stoltz, but enunciated before by Weitbrecht and supported in passages of De Graaf, Verheyen and Cazeau. This view is opposed to the notion of the cervix gradually diminishing in length with the progress of pregnancy, as commonly taught in the present day, and as was believed by Montgomery, Gooch, Desormeaux and others. Dr. Matthews Duncan has always taught that these views are erroneous, and the chapter is a fair review of the controversy. It strikes us, however, as one of the least interesting, and aptly illustrates the weak point of the book, that it appears too much of a *rechauffé* of articles published long ago. In some of the chapters the interest is such that this is forgotten. In this instance it has not been by the reviewer, but that after all may be his own fault.

In the next chapter are related some very interesting cases in which portions of the membranes or of placenta were retained for a considerable time, and which show that such imperfect delivery may or may not set up fetid discharges. When it does so it will attract attention, but inasmuch as such a symptom may occur from other circumstances the cases possess a twofold interest.

We may cite as a warning to the ignorant, reckless, and overweening specialists, who place all their hopes of success on the skill with which they can introduce the speculum, one incident in one of the cases.

Before Dr. Duncan saw it some one had come to that diagnosis which seems to be a sort of refuge in all cases of discharge—ulceration, and accordingly the patient had been subjected to the usual course of speculum and caustic.

We have no more wish than the author to decry a mode of treatment often found useful, but we may take the opportunity of protesting against what is a rapidly increasing abuse.

The 9th chapter concluding part III. is a brief one on imperfect development and hypertrophy of the decidua of which the author has met with one or two examples, but concerning which he has not much to tell us.

The woodcuts he gives, however, are very clear, as are the whole 40 with which the work is adorned.

We have far exceeded the limits allotted us by the editor for a notice of these two volumes on obstetrics, but we trust their importance and the difficulty of conveying in a few sentences an outline of such extensive researches, will be appreciated by the reader.

Dr. Matthews Duncan has done well to collect his contributions. They are in their present form the finished productions of a ripe scholar. Such laborious researches redeem the obstetric branch of our profession from the common taunt that its practitioners are too frequently engaged in personal squabbles to advance the science of medicine as much as they ought.

DECORATIONS OF HOSPITAL WALLS.

IT is not often that as medical journalists we are called upon to devote a paragraph to the Fine Arts, but there is just now in London an exhibition which claims peculiar attention from medical men. In the gallery of the Institute of Painters in Water-Colours, 53, Pall-Mall, there is a collection of sketches by Mr. ABSOLON which are intended, a week or two hence, to be transferred to the walls of Guy's Hospital. These ten large pictures are reproductions of that well-known artist's works, and their own merit as well as their destination will not fail to attract notice. It seems that like many other noble and generous minds, Mr. ABSOLON'S has been moved by the miserable appearance of the bare walls of most hospitals, and that he has been thereby stimulated to inaugurate a reformation by presenting these copies of his more celebrated works to Guy's. He calls the collection the "pleasures of memory," and long may he live to enjoy these pleasures, and feel that he has imparted to many a sick and sorrowing heart, the cheerfulness which seems to have its abode in his own, and to find so full an expression in his works.

There is something very depressing in the constant view of white-washed or painted walls—something which speaks too distinctly of the emptiness of life, and the painful struggle after the sublime and the beautiful. When the body is prostrate with sickness and pain, the ray of fancy that may serve to light the soul should not be quenched in the darkness of nothingness, but stimulated to its fullest exercise, that it may merge weariness into dreams of rest and peace. Such pictures as those which have called for these remarks may well contribute to the healing power of the other comforts of Guy's.

There is another thought which the subject has called up and may as well be expressed. There are many good people who, having spied out the nakedness of the land in many charitable institutions, have, with excellent intentions, but little judgment, filled up the blank spaces on the walls with placards containing texts of Scripture or other religious quotations. Now, there is nothing beautiful in an ordinary printed placard—however striking it may be. It is more appropriate to the advertising Sandwich than to

the sick-room, and in itself almost challenges the eye as a vulgar intrusion. But this is not all our complaint. Our estimable religious friends have been guilty of a much grosser want of taste and refinement, if not even of Christian charity. They have hung up in the wards of the charities they patronized texts which they had no right thus to force upon the constant attention of their sick brothers and sisters. It will not be denied, we think, by any one who reflects for a moment, that no frail mortal is justified in assuming that every other is only "a vessel of wrath." By what authority, then, do our good friends address the sick and suffering as all wicked—as all "given over to evil"—as "led captive by the devil at his will"—as the "children of the evil one"? Let them show their authority for this, and they may be excused for constantly parading the warning to "flee from the wrath to come"—the call to "resist the devil"—the almost unnecessary reminder that "the way of transgressors is hard": but even then, we think, it will be admitted that there is no occasion for the comminatory passages which form so large a part of these repertories. It is no extenuation to say these are all to be found in Scripture. So are others with which patients might well retort upon their patrons—such as "judge not that ye be not judged," and that significant text about the beam and the moat in the eye.

No doubt there has never been any unkindness intended. We are ready to give the managers who suffer these placards as well as those who present them, credit for the best intentions; but we cannot be blind to the inappropriateness of many that we see. We will give an example from recent personal experience.

At a hospital where we lately did the duty of one of the physicians, there were suspended in the view of all our patients these texts in large characters—"The wicked shall be turned into hell," "All ye like sheep have gone astray,' "He that believeth not shall be damned." On remonstrating against this we were informed that they were the gift of a clergyman who was on the Committee of the hospital, and that their removal would certainly be disapproved.

Finding they had been there for a long time, and observing that they were very dirty, we substituted for them similar placards, with the texts, "God is love," "Like as a father pitieth his children, so the Lord pitieth them that fear Him," "Believe on the Lord Jesus Christ and thou shalt be saved."

It may be a mere sentiment, but we cannot get over the feeling that the latter are far more appropriate to the sick-room than the former, and if we are to have Scripture thus paraded before the eyes of our patients, let us have courage to express our opinion that the weary and worn frame of sickness does not imply hardness of heart, or call for the stimulus of denunciation. Rather we should say would it dispose to a deeper appreciation of the Infinite Love—a calm reliance on the promise of the All Merciful. At any rate, we may be sure that well-grounded hope will do much to second our own ministrations; while the excitement produced in many timid natures by threats of awful terrors, may go far to nullify our treatment, as well as to frustrate the intentions of those whose judgment has been blinded by their zeal.

ABYSSINIA.

The third and fourth sections of Mr. Markham's communications, which were read before a meeting of the Royal Geographical Society, and the former part of which we noticed in a previous number, relate to the passes between Howakel Bay and Senafé. The first is the Teconda Pass, up which the advanced brigade was led in the beginning of December. Koomayloo at its entrance is 433 feet above the level of the sea. The road winds a distance of eight miles through gneiss mountains, which rise perpendicularly on either side up the bed of the Nebhaguddy to Lower Sooroo. There are here evident traces of volcanic action. One which cannot be overlooked is a vertical crack in one of the cliffs about five feet wide, filled with a black volcanic rock, which at a distance might be mistaken for a broad black mark, drawn for some purpose or other on the face of the rock. At Middle Sooroo the road turns suddenly to the right, and enters a pass not more than from 50 feet to 100 feet across, while the mountains on each side rise to a height of 1000 feet. Here for a distance of 250 yards were immense boulders of gneiss heaped together in great confusion, which have been removed. Twelve miles from Koomayloo is Upper Sooroo, which is 2520 feet above the level of the sea, where the pass opens again. From this place to Rara Guddy there is an excellent natural road, which, with very little labour, was made passable for wheeled traffic; and eight miles further on is Senafé, situate on the table-land, at an elevation of 7464 feet above the level of the sea. Though the country is wild, and but few signs of civilization are found, yet the difficulty of progress is by no means so great as might have been expected. Mr. Markham observes:—

"I have been in the Alps and Pyrenees, have walked or ridden up nearly every pass in the Western Ghauts of India, from Bombay to Cape Comorin, and I confidently affirm that in none of these ranges is there any natural opening which is so easily accessible as that from Komayli to the highland of Abyssinia. One peculiar feature in these Abyssinian mountains is that the passes leading through them have easier gradients and are altogether more readily surmounted than those of almost any other mountainous range in the world."

It was found that at Upper Sooroo there is plenty of excellent water supplied by a stream which is four miles in length from its source to its disappearance at Lower Sooroo. Further on, a plain was passed where there were guinea-fowl, candelabra trees and aloes. Here the scenery becomes very striking and beautiful, while the cliffs, as the party passed on, seemed to rise higher and higher, with the peaks of the mountains towering up into the sky behind them. The vegetation too was richer and more varied. Near the schistose and quartz rocks there were figs, peepul, banyan, sycamore, tamaux, tamarind, jubub, and solanum, trees and plants; and at Rara Guddy, where again there is a good supply of running water, in addition to these there were the mimosæ, and evergreen bush with sweetly-scented flowers (*myrsine Africana*), lobelia, wild thyme and the graceful clematis climbing over the trees. Though as a set off "in some places there was a perfect plague of locusts, which rose from the ground in myraids as the party approached, their innumerable wings making a loud crackling noise." Monkeys, also, were numerous in some parts, and flocks of vultures were attracted by the carcases of the mules.

Some considerable apprehension has very naturally been felt that the heavy rains of the highlands would swell into torrents destructive of the roads which pass through the gorges of the mountains, and thus interrupt the communication between the sea and Senafé, the base of operations

on the table land. Mr. MARKHAM'S observations, however, lead to the hope that these fears are to a great extent groundless. He noticed that the area of drainage is comparatively small, and mainly carried off by a gorge which leads to the Ragolay river, so that if a flood occurs it must be from an unusually heavy rain, which he considers is the exception and not the rule. Besides which he saw in the channel trees growing, which by any large swell and fierce rush of water must have been uprooted and carried away, while he found no marks left on the rocks or elsewhere of a subsiding flood—from all which it seems presumptive that the necessary intercourse between the sea and Senafé may not be materially obstructed.

The camp is situated on a plain, and is nearly surrounded by sand-stone hills and rocks. At no great distance, at the foot of a large mass of sand-stone rocks, stands the village of Senafé, formed of about a dozen houses, very roughly built, containing a population of 240, all Mahomedans, a black race with woolly hair. Further on in the valley are 15 other villages, making the population altogether about 5000. These latter villages are all Christian. Parts of the valley have excellent pasture, while others are ploughed and yield crops of barley. The flora is various, among which are found dog-roses, violets, and cowslips; and on the slopes of the hills, trees and shrubs of a warmer climate. Many of the views from the different localities are exceedingly striking and magnificent. In some parts of the cliffs there are large boulders and deep caverns, which form the lurking places of panthers and hyænas, but as yet no lion, or other wild beast, or snake has made its appearance. All that is known of the climate at present, after so short a time for observation, is that in the dry season the nights are cold, and the days cloudless and warm, while in May the rains set in, and continue more or less heavy till September, submerging the pastures, and rushing in torrents down the water-courses.

From later accounts we learn that the British advanced guard has reached Antola, which is about half-way between the sea-coast and Magdala, and the other half must be traversed before any direct effort can be made for the release of the captives. In a civilized community where facilities of transport already exist, 200 miles would present but a slight obstacle, which ten days, or at most a fortnight, would suffice to overcome. But in a country of which comparatively little is known—wild and mountainous as well—through which, as experience has already taught us, the roads have to be made before the forces can advance, where almost all supplies of food for man and beast must be brought the whole distance from the sea, and where other impediments will undoubtedly be met with—it is impossible to tell how long time may elapse before reaching the spot where the object of the expedition is to be achieved. Sir ROBERT NAPIER is undoubtedly a man of energy, and as a Commander no better could have been chosen; but even he cannot do impossibilities—even he must yield to necessity. If he succeeds in reaching the fortress of King THEODORE before the rainy season commences, the end may in all probability be readily attained. But then there is the march back, and when the rains once begin, no one can foretell the perils and obstructions which the retreating army may encounter before gaining the sea-board again. Who may have been the cause of the affront to the Abyssinian monarch, which has led to all that has happened, and may still happen before the affair is ended, we presume not to ask; but his Majesty will have ample revenge upon us in simply withholding the prisoners, and compelling us to spend untold millions for the sole purpose of wresting them from his grasp.

Notes on Current Topics.

The Public Health.

THE Registrar-General records the following particulars. There were 4743 births and 2934 deaths in London, and 13 other large towns of the United Kingdom, the annual rate of mortality being 24 per 1000 persons living in the week ending March 21st.

In London, 2299 births were registered in the week; the average number is 2218 corrected for increase of population; and the deaths in London were 1298, which is 301 less than the estimated number for that week. The annual death-rate was 23 per 1000 in West London, 22 per 1000 in Central and East London, and 21 per 1000 in North and South London.

"The annual rate of mortality last week was 22 per 1000 in the whole of London, 28 in Edinburgh, and 24 in Dublin; 19 in Bristol, 23 in Birmingham, 25 in Liverpool, 30 in Manchester, 31 in Salford, 21 in Sheffield, 25 in Leeds, 27 in Hull, 27 in Newcastle-upon-Tyne, and 31 in Glasgow.

"The deaths from zymotic diseases were 234, the corrected average number being 324. Twenty deaths from small-pox, 31 from measles, 20 from scarlatina, 9 from diphtheria, 46 from whooping-cough, 37 from fever, and 19 from diarrhœa were registered.

"One hundred and eighty-seven deaths occurred from phthisis, 111 from bronchitis, 79 from pneumonia, and 64 from diseases of the heart."

The Royal College of Surgeons of England.

ALREADY some little flutter has been made by our contemporaries over the probable candidates at the next election of Councillors. It is too early to say much. Some of the so-called candidates will probably decline to be nominated, and others may appear. Mr. Cooper has publicly announced his candidature on the ground of seniority and of liberal views. Mr. Erasmus Wilson has also declared himself ready to contest the election, and he will doubtless be one of the favourites. His high scientific standing, and long devotion to one branch of professional work, will not fail to enlist many in his favour. It should be known, too, that he is, *in one sense*, the senior Fellow *by examination*. In explanation of this term, we remind the reader that before the grade of Fellow was made, certain members were admitted to a voluntary examination as to their fitness for teaching. Mr. Wilson at once presented himself, and passed this examination. When the new charter was obtained he naturally appeared amongst the first list of fellows. Mr. Wilson comes forward, pledged to support the rights of fellows and members. He is in favour of voting by proxy, would separate the offices of councillor and examiner, would make the results of the discussions of the Council public, and give the fellows the opportunity of discussing matters relating to the general welfare of the College.

We expect that Mr. Luther Holden will again come forward, and the friends of Mr. Simon are anxious to see him on the Council.

There will, therefore, be no lack of liberal candidates, and fellows would do well not to make too hasty promises, but to see who will bid highest.

Lambeth Workhouse—the New Master.

THE recent appointment of a master to the Lambeth Workhouse was brought before the House of Commons on Friday week. Sir M. Beach, in his first speech since his appointment as Secretary of the Poor-law Board, explained the circumstances under which Mr. Catch had been requested to resign his former position, and maintained that he had been guilty of nothing to hinder his employment in a similar capacity. The Board had explained the facts of Mr. Catch's career to the Guardians, who had unanimously confirmed his election. The papers being now produced, further discussion may be expected.

The Wigan Workhouse Case.

OUR readers will not have forgotten the shocking event in the Wigan Workhouse last January, when a poor little infant was scalded to death by an imbecile nurse. This nurse was last week tried at the Liverpool Assizes on a charge for manslaughter, and of course acquitted. Why punish an idiot for doing badly what she ought not to have been set to do at all? We were delighted to read in the daily papers that the judge severely censured the authorities of the Workhouse for putting such responsibilities upon poor creatures like the prisoner. His Lordship said, that if these authorities had been placed in the prisoner's position, they would have had great difficulty in defending their conduct. This remark conveys a very useful hint. Why should they not have changed places with the unfortunate idiot? Is there no way of bringing home, in this practical way, to all officials a proper sense of their responsibilities?

Workhouse Infirmaries Association.

A DEPUTATION appointed by this association was received on Saturday, the 21st ult., by the Earl of Devon, President of the Poor-law Board. Several noble Lords, various Members of Parliament, and other gentlemen, were present on the occasion. The Archbishop of York, who was at the head of the deputation, first addressed the President. After referring to the evils of the present system of workhouse management, which he detailed at some length, and corroborated by quotations from the report of Mr. R. B. Cane, Poor-law Inspector, his Grace expressed a hope that it would not be thought the deputation had come to his Lordship in "any spirit of dictation." Their sole object was to express a wish that the Poor-law Board might be entrusted with larger powers, that the requirements of infirmary establishments might be more clearly indicated, and authority given to the Board to inforce them; that an auxiliary corps of medical inspectors might be appointed to examine and report on the nursing, medical attendance, sanitary arrangements, diets, medicines, &c., in the workhouse infirmaries; and that dispensaries might be established for the out-door sick.

Several others addressed his lordship in support of the objects which the deputation sought to attain, and the Earl of Devon replied, assuring them of the satisfaction with which he had listened to the views they had expressed on the subject before them. He considered the Board was much indebted to them for their influence in promoting the important changes made last session in the administration of the Poor-law in the metropolitan district, though he questioned whether the House of Commons would give the Board the powers which the deputation seem disposed to ask for, and whether the metropolitan and country districts were so much alike that the same regulations would apply equally. He stated that the Board proposed certain alterations in the reports to be sent in by the Inspectors, and that the medical officers would be required to keep a separate book for detailed information to be laid before the Guardians, on points connected with the infirmaries and the sick. He acknowledged that great deficiencies existed, but believed that these and similar regulations would give the Board more regular and effectual supervision. As to dispensaries, he said, though the metropoliton ones worked well, he was not prepared to say whether it would be proper to establish them in country districts. There was, however, nothing to prevent the Guardians from establishing them in connection with the workhouses, and the Board would have every disposition to aid them in that object. After presenting their thanks to the noble Earl, the deputation withdrew.

The Rating of Charities.

SOMETIMES the Legislature, unwittingly, destroys a just and long-recognised policy, by decisions relating to other interests which apparently have no connection with it. Three hundred years ago, when the Poor-law was first enacted, it was an admitted principle, which has ever since been acted on, that all charitable institutions should be exempt from Poor-rates; but a decision of the House of Lords, two or three years since, respecting the Mersey Docks, rendered them all liable to assessment by the parish authorities. General attention has been excited, and on Tuesday week, a large deputation of gentlemen from the principal cities and towns of the Kingdom, headed by his Royal Highness the Duke of Cambridge, and the Earl of Harrowby, waited on the Premier and the Chancellor of the Exchequer, to bring the subject before them. The Earl of Harrowby introduced the deputation, and spoke to the question generally. The Duke of Cambridge attended as President of Christ's Hospital, and other gentlemen on behalf of the various insitutions in their respective localities. From the testimony of all, it appeared that the effect on the charities generally would be depressing, and in many cases disastrous, as the benefits conferred by these institutions must be very much restricted, and many schools necessarily given up, if the rates are imposed. Mr. Disraeli in reply to the various addresses said, that he had listened with great interest to the statements of those around him, and thanked them for drawing the attention of Government to a question of such great social importance. He promised them that it should be considered in a spirit adequate to the occasion, and to the importance of that assemblage.

Troops in Mauritius.

ON Friday evening, in the House of Commons, Sir J. Pakington stated that orders had been sent out for a strict inquiry into the circumstances underwhich a regiment had been suffered to land in Mauritius, when the island was in an unhealthy condition. He further added, that last year he sent out orders, giving full power and discretion to the officer in command to remove the troops whenever the health of the island rendered that step advisable, and to prevent mistakes he had repeated these orders.

In the face of this the country will want to know more about the case, and the report of the "strict inquiry" ordered will be impatiently expected.

The Contest for the West Middlesex Coronership.

Since the election of Dr. Diplock to the office of Coroner, as recorded in a recent issue of The Medical Press and Circular, Dr. Hardwicke has taken active steps to follow up the proceedings necessary to test the validity of that election, and appears to be sanguine of success in the attempt to unseat Dr. Diplock. It was stated on his part, at a recent meeting of the ratepayers at Acton, that Dr. Diplock had not polled more than 500 *bona fide* freehold votes, the rest being made up of questionable and illegal elements. Of this nature were the votes of 300 odd graveholders (Dr. Hardwicke 100) and 277 watermen (Dr. Hardwicke 76), which, if struck off, would give Dr. Hardwicke a sweeping majority. Men, he added, had been brought up from Poplar, Limehouse, Woolwich, and Westminster (places not in the western division at all) and had recorded their votes for Dr. Diplock. Dr. Hardwicke had placed himself in the hands of a committee connected with the medical profession, who had made up their minds to see this issue to the last, no matter what it should cost.

The Punishment of the Lash.

The repudiation of corporal punishment by the House of Commons, after a thorough discussion of the subject, in which its advocacy was backed by an appeal from Government, was an assertion of principle which cannot be misunderstood or disregarded. In a House of 280 members, and by a majority of 25, Mr. Otway carried his condemnation of the practice, and by this vote the "cat" no longer "harmless" or "necessary," has been taken from the hand of those who apportion the soldiers' punishment. We can record an unqualified approval of this step, without identifying ourselves with mandein humanitarianism or sympathy with ruffianism. We do not commend the abolition of the lash because there is anything essentially wrong in its use, but because the cases in which its use is applicable may be dealt with, in our opinion, more effectually by other means. Every one is aware that there are school boys whose feelings can be reached by no gentler persuasion, and who are all the better for an occasional flogging, but they are whipped because there is no other way of getting over the difficulty. If they were salaried servants as soldiers are, we would consider that our service was better without them, and would turn them out of it incontinently, and this is at the same time the most desirable and most economical means of dealing with the refractory soldier.

Hospitals for Contagious Diseases.

The sum of £20,000, included in the vote of £968,400 for buildings which elicited so much debate in the House of Commons last Wednesday, is an appropriation of the public money which is hardly open to cavil, even from the most rigid economist. That it should appear in the estimates at all under the circumstances of a vote so largely increased as to make necessary an apology from the Secretary for War, is an evidence that the authorities are thoroughly alive, not only to the urgency of the requirements of the service in this respect, but to the magnitude of the results which have accrued from the working of the Contagious Diseases' Act.

We earnestly hope to see the system, when it has been confirmed by the test of time, applied to the civil population, and we can conceive no sensible reason why a real and tangible gain in the public health should be confined entirely to the public services. We hope it will not sound disrespectful if we say that the movement for counteracting the extension of venereal disease in the Army and Navy is a financial movement altogether. The War Office has not entered on a crusade for the moral reformation of soldiers and sailors, but have simply arrived at the practical conclusion that prevention is cheaper than cure, and that it costs less money to check the propagation of the disease in its original source, than to maintain in idleness the numerous victims, whose time represents so much current coin, and to pension off a certain percentage of educated and valuable men. The principle, if not very admirable, is at least likely to prove more lasting than any moral consideration, because, in the form of pounds, shillings, and pence, it will annually come home to the comprehension of the War Office and the House of Commons. The same incentive for the application of the same principle to the civil population, must be less forcible, though we have no doubt that even in an economic point of view, a check on the unlimited spread of venereal disease will commend itself to thinking men, and the moral and physical gain to the public cannot fail to force itself upon general attention when we are more fully informed of the working of the system. Extraordinary as the paradox may seem, the theory has been started, and that in no ambiguous language, that it is the inalienable right of the free-born Briton to acquire and retain syphilis in any form he may desire, from the chancre to the node, and to propagate the same as he may have the occasion, and that any proposal to restrict that right is an invasion of the provisions of Magna Charta. In substance, and almost in words, this refusal has been given to the request for his co-operation by a gentleman connected with the University of Dublin, to whose opinion usually much authority is attached, and whose cloth might be supposed to confer a prejudice in favour of the moral view of the question. If we must notice such a theory at all, we would say, as we have said before, that no interpretation of the liberty of the subject ever could entitle a person to extend pernicious results of his acts beyond his own person. No one is allowed to propagate small-pox, or to annoy others by abuses of appetite, and in a much greater degree the propagation of syphilis ought to be reprehended. We can hardly conceive that such a theory is seriously put forward, and we can rest on the belief that it is too monstrous to be received, even from the source from which it comes.

The Scottish Universities.

We hope the signs of jealousy evinced by a section of Edinburgh graduates towards their brethren of St. Andrews will soon pass away. The senate refused to join in a factious and unworthy opposition to the just claims of St. Andrews got up by the University Court, a body consisting of only eight members.

Dr. Alexander Wood and Dr. Christison were both present at the meeting when this illiberal vote was agreed to—the latter in the chair. It is well to know who are ready to advocate the erection of petty boroughs under the pretence of University constituencies. Should Parliament take notice of this jealousy, it might adopt the suggestion that has been made of giving only one member to the four Scotch Universities. In that case, the profes-

sion would not forget to lay some of the blame on those who were so illiberal.

Steps have already been taken by candidates for the seat to be conferred on St. Andrews and Edinburgh Universities. Mr. Campbell Swinton's friends have issued a circular in the legal interest. Dr. Lyon Playfair's have adopted a similar course in hope of securing the medical votes. We have heard on excellent authority that Mr. Moncrieff will be solicited to stand, and that if he consents, he will obtain much legal support. Besides this, we know that two or three physicians are thinking of seeking the support of the medical graduates.

Gagged to Death.

It is not in the least necessary to a feeling of unmitigated disgust to assume that the sailor who died on board of the "Favourite" under the use of the gag, lost his life by suffocation, for the infliction of so cruel an ordeal is sufficiently abhorrent to humanity to insure its earnest condemnation. The evidence of the medical officers that the gag did not prevent respiration was perfectly true, but it may have given rise to præcordial excitement or depression, which would have been as fatal as asphyxia.

Therapeutical Committee of the Harveian Society.

We are requested by the Secretary to say that at the first meeting of this Committee, held on the 13th inst., at the house of Dr. Fuller, it was determined to commence proceedings by taking up the following subjects for investigation, viz :—The *natural history* of rheumatic fever and its treatment by, first, alkalies ; second, blisters. The natural course of acute idiopathic pleurisy, and its treatment by calomel and opium with fomentations, iodide of potassium and fomentations ; and the natural course and treatment of acute eczema. Several sub-committees were appointed to carry out the different inquiries.

It was also resolved to circulate the subjoined questions amongst the medical men of the United Kingdom, and to ask the co-operation and assistance of the profession generally in carrying out the objects of the committee:—

Queries.—Have you found any of the following drugs, viz :—Digitalis, Cantharides, Chlorate of Potash, Belladonna, Arsenic, Quinine, and the Tincture of the Muriate of Iron (as distinguished from the other forms of Iron), particularly useful in any special form of disease? In what form of preparation and in what doses are you in the habit of administering these drugs ; and what results have you observed to follow their administration in the diseases to which you refer?

Can you, from your personal knowledge, give any information respecting the use and doses of any drug not commonly employed, or respecting any method of treating any disease, which you have found particularly useful in your practice ; or can you give information as to any fact in therapeutics not commonly known to the profession?

Answers to any of these queries will be gladly received by the Honorary Secretaries, J. B. Curgenven, Esq., 11, Craven Hill Gardens, W., and W. Hickman, M.B., 1, Dorset-square, N.W., of whom copies may be had, and any further information obtained.

Dr. Gale, whose recent suspension will be remembered, has been restored to office by the Poor-law Board.

Dr. Gee has obtained the office of Assistant-Physician to St. Bartholomew's Hospital, and Dr. Tatham a similar post at the Brompton Hospital.

The Guardians of St. Pancras, according to a report we have just received, deserve great credit for the improvements they have effected during the past year.

Dr. Crane has issued a report on the health of Leicester, which shows the town to be in a good sanitary condition. He is to be congratulated on the manner in which he has performed his duties as health officer.

The Regius Professor of Physic at Cambridge will commence his course on Pathology on the 22nd of April.

MEETING OF THE PROFESSION AT MASBRO'.

As announced in a former number the meeting of the medical profession was duly held at the Prince of Wales Hotel, Masbro', to endeavour by united and unanimous action to raise the present payment made by the various sick clubs and societies for professional attendance during sickness or disablement. Dr. Blythman, of Swinton, presided, and there were present Messrs. Hardwicke, Robinson, and Wilkinson, Rotherham ; Crossley, Maltby ; Carmichael and Walker, Masbro' ; Muir, Wombwell ; Clarke, Wentworth ; J. Burman, W. Burman, and W. Syson, Wath ; J. H. Casson, Riddings ; W. T. P. Smith, Barnsley ; H. Walker, Sheffield ; and Drew, Chapeltown.—In opening the meeting, the Chairman remarked that whatever was resolved upon should receive his cordial support. —Dr. Syson, the hon. secretary, said the gentlemen would see by the circular they had received what was the object wished to be attained. He contended that three shillings per head per annum, the average payment in that district, was wholly inadequate considering the increased price of the articles required. He had had five years' experience of this fact, but it could not be remedied except by unanimous action.— Dr. Hardwicke said that in the Rotherham district they had nothing under four shillings.—Dr. Robinson suggested that the scope of the meeting should be enlarged, and that a Medico-Ethical Society be formed the same as at Manchester and other places.—Mr. Clarke was of the same opinion. Speaking of the working men, he said they were utterly improvident while earning wages, and when they were struck down by sickness, they were exceedingly careless as to the payment of their medical account. Nineteen out of every twenty in his district would not pay for attendance for their wives and children unless they were summoned in the County Court ; hence it was necessary the profession should unite and work for their mutual benefit. For a number of years he was surgeon to a large ironworks in Scotland, and an arrangement was there made whereby the men received medical assistance for themselves and families, and he thought if a similar course was adopted here it would be of advantage. —After a long and desultory conversation, it was resolved, on the motion of Dr. Hardwicke, seconded by Dr. Syson —"That it is the opinion of this meeting that united and unanimous action should be taken to fix the minimum for medical attendance on clubs and sick societies at 5s. (within a radius of three miles) ; clubs to be at liberty to contract for surgical attendance as well by payment of 1s. per head extra per annum."—It was further resolved, on the proposition of Mr. Crossley, seconded by Dr. Drew—"That surgery be defined to include all cases the payment of which is not provided for by the Poor-law Board."—Dr. Smith moved, and Mr. Carmichael seconded—"That every certificate granted beyond the club, which a medical man attends be charged 1s. as a minimum."—The proposition was adopted. After deciding to form some such society as that suggested, the meeting separated.

Scottish Registrar-General's Report.—From this report we select the following particulars which will chiefly interest our readers. They show that the year 1867 was characterized by a low rate of mortality in Scotland. The deaths in that year reaching 69,024, amounted to 21·45 per thousand, the average of the ten previous years being 21·8 per thousand. In England the death-rate was 21·9 per thousand, which also was below the previous ten years' average of 22·5 per thousand. The improvement in the mortality of Scotland, in 1867, was entirely in the rural districts. In these the ratio was only 16·2, the average being 17·0 per thousand; in the town districts the ratio was 25·8, the average being 25·5. The mean of 55 meteorological returns in Scotland shows a mean temperature of 45·7 deg., in 1867, the highest 85 deg. and the lowest 6 deg ; the mean daily range 11·5 deg. Amount of rainfall 38·52in. Hours of sunshine only 1·518.

Proceedings of Societies.

SURGICAL SOCIETY OF IRELAND.

FEBRUARY 28, 1868.

Mr. PORTER, Vice-President of the College, in the Chair.

(Continued from page 276.)

ON THE USE OF CARBOLIC ACID IN THE TREATMENT OF SOME CASES OCCURRING IN THE SURGICAL WARDS OF THE MATER MISERICORDIÆ HOSPITAL.

MR. TYRRELL said—Mr. President, I have published in the *British Medical Journal* of the 18th of last January, a report of three cases of acute bursitis treated by early incision and carbolic acid, and in the same communication expressed myself warmly in its favour. As my opinion, after further and more extensive experience, is somewhat altered, I think it only proper that I should lay before the Surgical Society, the details of some of the cases which have caused the change.

I need not remind the Society, how much surgery is indebted to Mr. Lyster, for the introduction of the antiseptic principles of treatment in surgery, and so much interested was I with the report read in Dublin before the British Medical Association last summer, and so anxious was I to see its efficacy tested, that I went to Glasgow last September for that purpose. There, Mr. Lyster's house-surgeon most kindly explained to me (in the wards of the Royal Infirmary) the manner in which it was used, and also dressed some cases while I was in the hospital. He spoke in the most eulogistic terms of its great use.

I also paid a visit to Edinburgh, and Mr. Syme most kindly brought me through his wards, where I saw several cases dressed with the carbolic acid precisely as in Glasgow. My stay, in either city, was not sufficiently prolonged, to allow me to watch, for myself, the progress of the cases under the carbolic acid treatment.

On Wednesday, 8th of January, I amputated immediately above the wrist the hand of a man named Baxter, who had been admitted into the Mater Misericordiæ on the 5th of last December, for extensive epithelioma of the back of the hand.

Two arteries merely were ligatured, and one twisted with Syme's torsion forceps, an instrument which I can confidently recommend as a sure means of arresting hæmorrhage from comparatively large arterial trunks when properly used. The wound was sponged with the carbolic lotion, as recommended by Mr. Syme in his article entitled—"Illustrations of the antiseptic principle of treatment in surgery," which was published in the *British Medical Journal* for January the 4th, and the stump dressed with the carbolic oil.

The dressing was removed on the 4th day, and it was remarked that the edges of the wound were adherent, but not firmly united; the stump was neither painful, red, nor hot. I was quite delighted, and remarked that the patient would be quite well, and the wound completely healed, in a few days. The same dressing was reapplied. On the sixth day, however, suppuration was fairly established, the edges which had been united were separated, and as the patient complained very much of the smell of the carbolic acid sickening him, I had no hesitation in substituting simple tepid water dressing for it, as it had failed to procure the early union for which I sought, and had most confidently expected.

The man was dismissed from hospital, quite recovered, a few days since.

Case 2.—Mrs. Brennan, aged 50, a strong healthy woman, was admitted on the 14th of January under my care, for the removal of a large fatty tumour (it weighed after removal two pounds), situated between the scapulæ. It was ten years growing. I performed the operation on the 22nd. The skin was with difficulty separated from the tumour; one or two vessels bled rather smartly and were twisted; sponged the wound with the carbolic lotion, stitched the wound with wire sutures, and applied a plaster of carbolic acid.

The wound was not disturbed till the 4th day, when, upon taking off the carbolic acid plaster, the lips of the wound were found not to have united. I removed the sutures and dressed the wound again with carbolic acid paste. On the 6th day again removed the dressing, and found a copious suppuration established. The cabolic acid was now given up, and warm tepid dressing substituted in its place.

The wound healed very slowly; it was only last Monday she left the hospital.

Now, although in the two cases just detailed I took every precaution, and followed accurately the directions of Mr. Syme, still primary union was not obtained in either, although the patients were in apparently excellent health. I think it but proper to lay them before the profession, even at the risk of being told by so distinguished an authority as Mr. Syme, that such testimony tends to reflect more on the practitioner than on the practice.

I shall now read a report of two other cases, in which the carbolic acid treatment was most satisfactory.

Case 3.—A little girl, æt. 10, of decidedly strumous diathesis, was admitted last month under my care. She had several scrofulous ulcers on the left leg, and a small chronic abscess in the lower part and external side of the right thigh.

I laid open the abscess under a curtain of the carbolic oil. The dressing was removed on the fourth day. There was a slight serous discharge from the wound on pressure. I reapplied the dressing, and in two days more the wound was quite healed.

Case 4.—Patrick Farrell, æt. 19, was admitted on the 9th of last November. He was in a most pitiable state, worn down by want of rest, literally covered from head to foot with large eczematous patches, from which exuded—here a serous, there a purulent discharge; in some places deep cracks or fissures were present, and daily large dry crusts were detached. An abominable stench was exhaled from the entire surface. He stated he was labouring under his present illness for the last six years.

As both sides of his body were equally affected, I thought it a good case to try the relative value of different modes of local treatment, while I gave Fowler's solution in five ♏ doses three times daily, in conjunction with the occasional use of a saline and chalybeate aperient.

Accordingly, I desired two of my pupils to take charge of the case, and directed one of them to apply (as soon as the crusts had been removed by light poultices) various ointments, as a mixture of the spermaceti, pitch and sulphur, the ung. zinci. oxydi., &c.; the other to paint the opposite side with carbolic oil, in the proportions of 1 to 10.

It was remarkable how soon a difference was apparent between the two sides of the body; while the one to which the carbolic oil was applied was rapidly healing, the itching removed, and the fœtid odour counteracted, the other side showed very little tendency to get well. So marked was the difference that the patient himself begged to have his whole body given up to the student using the carbolic acid, which was accordingly done; and in three weeks the patient was convalescent. The excoriations and fissures were healed up, the intolerable itching was entirely relieved, and his skin no longer exhaled a fœtid odour. I gave up the use of the arsenic after having used it for a month, and directed him to take three draughts daily, each containing two grs. of carbolic acid. The carbolic oil was also applied daily over any spot which showed a tendency to return. I dismissed him last week, his skin clean and smooth.

Dr. M'Call Anderson, in his valuable treatise on eczema, speaks highly of the value of carbolic acid, and says there can be no doubt that it possesses many valuable qualities, and that it is destined ere long to play a very important part in therapeutics.

I think, sir, it would be most advisable that we should learn from other members of this society what has been their experience of the value of carbolic acid, and if the reading of this short paper has that effect I shall rejoice.

MR. CROLY would mention some cases in which he had used the carbolic acid dressing with great success—viz., a case of amputation of the breast, a case of severe injury of the hand from a circular saw, severing the thumb and four fingers, a case of gun-shot wound of the thumb which was amputated, a case of onychia in which he removed the nail, a case of fistula in ano, and a case of very unusual fracture of the lower end of the thigh where the femur protruded. He thought this dressing was one of the greatest successes in surgery, especially applicable in cases such as he had mentioned. The breast to which he had alluded healed with facility, and there was a complete absence of fetor.

MR. MCGRATH, 8th Hussars, had used carbolic acid dressing in the treatment of primary syphilis with great success, at least so far as the local symptoms were concerned. He had seen very lately a distinguished surgeon in Manchester use carbolic acid in the treatment of gonorrhœa. The acid was very much diluted with oil, smeared on a bougie, and used in the subacute stages of gonorrhœa. The opinion of that eminent surgeon was that it counteracted the generation of pus. In his (Mr. McGrath's) own hands it had not been so successful.

Mr. FLEMING said he had taken an early opportunity of testing the value of this very useful therapeutic agent. He had the advantage of seeing Mr. Lyster apply it in the Richmond Hospital on the occasion of his recent visit to Dublin. The first case in which it was used was that of chronic abscess of the lower part of the thigh. There were two modes of applying the carbolic acid, one as a liniment, the other as a lotion—in the latter the fluid being mixed with certain portions of cold drawn linseed-oil; and in the former the acid being used in certain proportions with water. The liniment was had recourse to in the case to which he referred, and unquestionably the result of the treatment was most successful. The opening of the chronic abscess was not followed by any of those evil constitutional symptoms which often supervened in such cases. The process of reparation was slow, but ultimately cure was effected, and no fever ensued. In three or four cases of chronic abscess he (Mr. Fleming) had used this dressing with satisfactory results, and he had found the lotion most useful in cases of amputation. In one case of a compound fracture of both bones of the leg he resorted to carbolic acid dressing. The constitution of the young woman, the subject of the accident, was most unfavourable, and the result had not been satisfactory as regards osseous union, but otherwise, the carbolic acid had the desired effect, no suppuration supervened, and the evil consequence of ordinary compound fracture did not arise. As to its use in gonorrhœa, if the lotion were weak it might be used with impunity. He had known it to have been used in a case of internal hæmorrhoids, which protruded after defecation, and were accompanied by a fetid viscous secretion. The gentleman who was thus afflicted had resorted to other applications without effect, but the relief he derived from the carbolic acid was extreme. He (Mr. Fleming) had used it as an injection in chronic catarrh of the bladder, particularly in those cases where the discharge was fetid, and Sir Henry Thompson had used it in cases of lithotomy. He thought carbolic acid deserved every attention from the profession as a useful addition to their therapeutic remedies.

Mr. HEWITT remarked that linseed-oil was liable to become rancid, and if used in such a condition with the acid, he could easily conceive that it might become an irritant. The cases in which it failed, however, should not interfere much with their opinion of it as a remedy; for each remedy depended for its effects on the vital conditions of the parts, and as the vital conditions of parts differed very much the effects of the remedy would also vary. That was the universal opinion of all who had turned their attention to therapeutics. He was not surprised, therefore, if in some cases carbolic acid did not prevent suppuration or cause cohesion.

Mr. BURNE said, that as surgeon to the South Union, he had seen a great many cases of gangrenous stomatis, and had treated them successfully with carbolic acid lotion, keeping the patients up by stimulants.

Dr. P. WHITE had seen the carbolic acid dressing used by his colleagues in Jervis-street Hospital, and it was to a very considerable extent a failure, and in no case was it so successful as had been described. There was one class of cases in which it was of great value, and in which he had been using it for four years—namely cases of eczema. A child who had gone the round of the Workhouses, recently came under his care, suffering from chronic-eczema of the scalp. Every other remedy had been tried but without success. He put the child under treatment by carbolic acid and glycerine, and in one fortnight the scalp was improved, and when removed to a Fever Hospital, having unfortunately been attacked by fever, she was perfectly cured of eczema of the scalp. He had used carbolic acid, also, in the form of eczema attacking the legs, arms, and various parts of the body with the same result. There was but one case in which it failed. He treated a lady a year and a-half ago with carbolic acid for eczema of the legs, and cured her. About a fortnight ago she again came under his care, suffering from the same affection. He thought he would improve the treatment by combining arsenic with the carbolic acid; but she came back with her legs literally covered with eczema, from the knees to the ankles. He then put her on iodide of potash, and Dr. Neligan's application, and she recovered; and he had a letter from her the other day saying, she was now perfectly well. With regard to the value of this agent in preventing fetor, he thought they were too much inclined to overlook the preparation of creosote. The odour of this was less unpleasant to him than that of carbolic acid, and its action was more efficient. He had used it both for correcting fetor in cases of gangrenous ulcers and wounds, and in cases of fetor or discharges from the intestines. He might mention a case, which was under his care, of a lady dying of diseased brain. She got an attack of fetid bronchitis. The fetor was removed by the use of chloride of lime. Following that, she was attacked with a most horrible fetor every two hours before the action of the bowels, fetor so great that no one could bear to come into the room. The chloride of lime failed, and he then prescribed creosote internally, and with the most prefect and marked success. She took the creosote pills regularly, and if it happened that one of them was omitted, which occasionally occurred, the fetor returned.

Dr. MCDOWELL said he had in his private practice a case of rupial syphilis, with extensive ulceration of the surface of the body. In this case, after he removed the scabs by poulticing, he employed carbolic acid in the form of a lotion, giving the patient at the same time sulphite of magnesia, and supporting his strength by stimulants and beef-tea. Under the use of carbolic acid the fetor was entirely removed, the pain was relieved, so much so that the patient could sleep without the use of anodynes, which before were necessary, and in a short time the ulcerated surface was completely healed. So satisfied was he of the efficacy of the carbolic acid that he was now determined to employ it in similar cases under his care in the Lock Hospital, the result of which he would bring under the notice of the society.

Mr. STOKES had had some experience of the treatment of wounds by carbolic acid, and could endorse all that had been said in its favour by Dr. Tyrrell and others who had spoken. There could be no doubt that this treatment of Lyster's was a very great improvement in surgical therapeutics. He should be sorry to say anything against Dr. Lyster, for whom he had the highest respect, but he thought it right to mention that three years ago he saw this treatment adopted in the Hotel Dieu, and his friend Dr. O'Grady told him that it was five years since Dr. Maisonneuve had first published his work on treatment by phenic acid, which was carbolic acid and water, in the proportions of 1 to 30. He (Mr. Stokes) had used it largely in the treatment of wounds and injuries in the Meath Hospital, and with uniform success.

Dr. RICHARDSON observed that he would mention two cases which were recently in the Adelaide Hospital. One was a case in which he amputated the thigh and used the carbolic acid, and in that case hardly a drop of matter formed from the beginning to the perfect healing of the wound. On the other hand, Dr. Barton amputated a thigh on the 15th of the present month, by Teale's method, and the greater part of the wound united by the first intention, although, he believed, carbolic acid was not used, showing how difficult it is, in many cases, to arrive at sound conclusions regarding the action of remedies.

Dr. HARGRAVE said that tar water and creosote were amongst the most valuable remedies which they possessed. Chloride of zinc, properly prepared, was one of the best means of correcting fetor, and it also acted as a powerful anodyne. In the City of Dublin Hospital he had a case of perineal cancer; the fetor was very great and the pain extreme. It occurred to him to apply chloride of zinc, and it not only removed the fetor, but gave the patient relief from pain, so that it was not necessary to give him opiates, which before he had taken freely. Within the last two years we had received from M. De Morgan, of the Middlesex Hospital, testimony as to the value of chloride of zinc. In removing the breast he washes the surface of it with the solution, and it heals in a most satisfactory manner. He thought it was a mistake to be running after new ideas and new medicines, which they often found to fail, while they neglected their old friends who had stood to them so well. He lately had a case of very extensive abscess over the sacrum. He treated it at first with iodine, and then tried carbolic acid, which gave some relief, but he thought if he had kept the patient on iodine she would be better.

Mr. TYRRELL, in reply, said he was gratified at having elicited the opinions of men who had had large experience in the use of this new therapeutic agent. He agreed with Professor Hargrave that they should not desert their old friends, but he thought at the same time they should try new ones, and if they succeeded, make the fact known. He had shown both the faults and the virtues of their new friend. He was not a great advocate for the use of carbolic acid in all cases; nor did he believe, so far as his practice had gone, that it produced union sooner than cold water. He had brought forward the result of cases in which it had failed, particularly as he had lately published some cases in which the treatment had been

successful. From what he had heard that night, he was sure carbolic acid was of great use, but he did not think the opinions of Syme and Lyster, as to its value, were fully borne out.

(After the chair was vacated, the men whose patellæ had been fractured, were examined by the members.)

DUBLIN OBSTETRICAL SOCIETY.

THIRTIETH ANNUAL SESSION, 1867-68.

SIXTH MEETING.

THE Society met in the Hall of the College of Physicians on Saturday, March 14,

Dr. HARDY, President, in the Chair.

The PRESIDENT announced that the Council of the Obstetrical Society waited upon the President and Fellows of the College of Physicians to request permission to have the use of the College Hall for the meetings of the Society, and that the request had been freely and cordially acceded to, and that, consequently, the meetings of the Society would for the future be held in that hall.

The following resolutions were then passed :—

Proposed by Dr. M'CLINTOCK, seconded by Dr. DARBY :—"That the marked thanks of the Society be given to the President and Fellows of the King and Queen's College of Physicians for their courtesy in granting the use of the College Hall for holding the meetings of the Society."

Proposed by Dr. SAWYER, seconded by Dr. FITZPATRICK :—"That our marked thanks are due, and are hereby given, to the Governors and Guardians of the Lying-in Hospital, for having granted to this Society the free and gratuitous use of the Rotundo Rooms, a privilege which it has enjoyed and exercised ever since its formation in 1838, and which it now relinquishes solely in consequence of the College of Physicians having kindly placed their hall at the service of the Society."

Proposed by Dr. CRONYN, seconded by Dr. KIRKPATRICK :—"That the Fellows of the King and Queen's College of Physicians be, and are hereby invited to be, present at the meetings of this Society."

Dr. C. F. MOORE exhibited an ovum of about six weeks or two months old, in which a large effusion of blood had occurred between the chorion and amnion, and stated—

D. D——, a tolerably healthy-looking woman, aged 30 years sent for me for threatened abortion on the 7th of March.

I enjoined rest in a cool room, and ordered a mixture containing sulphuric acid. On the evening of the 8th the tumour was expelled per vaginam, and I now beg to submit it to the society.

I am indebted to Dr. John Barker for being able to exhibit the ovum with the embryo admirably shown.

When I obtained the specimen it was distended with dark-coloured blood, effused outside the amnion.

D. D—— has been married about five years. She lately lost two children, a boy and a girl, of "measles and whooping-cough." The younger would have been thirteen months old if alive now. Very early on the morning of the 6th, she sustained a shock from fright, and it was on the evening of the 8th that the fœtus was expelled; altogether she lost a good deal of blood.

She last menstruated on the 2nd of January; she experienced "sourness of stomach" about a month or six weeks before the abortion occurred. I would, therefore, suppose the fœtus to be between four and six weeks old.

D. D—— was doing well when last seen.

Dr. BYRNE read a paper on retention of the menses from imperforate hymen, in which he detailed three cases.

Dr. HALAHAN read a paper on anomalies in the mechanism of parturition, wherein he stated that the head sometimes, though rarely, passes from the third German position to the first, and from the fourth to the second, external rotation taking the course usual where the third only changes to the second, and the fourth to the first.

Dr. J. GUINNESS BEATTY read a case of rigid perineum, in which the operation proposed by Dr. T. E. Beatty in a paper read before the Society in January, 1867, had been performed.

It was the woman's first labour. The head had been pressing on the perineum for two and a-half hours. The perineum was greatly distended, but the head made no progress. With a pair of scissors Dr. J. G. Beatty divided one inch of the perineum in the median line, and as the head was still retarded, he divided a quarter of an inch more, when the head was at once expelled, and without further laceration, and the patient made a good recovery.

Parliamentary Intelligence.

ON Thursday last, Sir J. SIMEON asked the Secretary to the Poor-law Board, what were the grounds on which the board accepted the resignation of Dr. Rogers, the late medical officer of the Strand Union; and whether that resignation implied anything unfavourable to the character or to the professional ability of Dr. Rogers.

Sir M. HICKS-BEACH replied that, owing to disputes that had occurred, the board of guardians had suspended Dr. Rogers on the ground that his conduct had been characterised by discourtesy, and had tended to bring the board into disrepute, and that his conduct had been such as to render it impossible that they could work harmoniously together. The Poor-law Board had inquired into the subject, and he was enabled to state that no complaint had been made of any want of professional ability on the part of Dr. Rogers, or of anything otherwise unfavourable to his character.

RATES FOR SANITARY IMPROVEMENTS.

Lord ENFIELD asked the Under Secretary of State for the Home Department, whether any defect existed as regarded the levying of rates for sanitary improvements in the provisions of the 49th clause of the Sanitary Act, 1866, and of the 2nd clause of the Sewage Utilisation Act, 1867; and if so, whether he proposed, during the present session, to bring in any measure to remedy the same, and whether any steps had been taken, under the provisions of the above-mentioned acts, to remedy the imperfect state of the drainage of Acton, Chiswick, and a detached part of Ealing, as reported to the Home Department in October, 1866, by Mr. Fulton, the Engineer.

Sir J. FERGUSSON replied that there was the defect in the law to which his noble friend referred. There was a question as to the power which the Home Secretary might exercise with respect to the overseers as regarded the levying of rates. The opinion of the law officers of the Crown was taken last year, and they seemed to be of opinion that the act did not give to the Secretary of State power to issue his precept for the levying of additional rates; but as his right hon. friend believed that the power was given, he was prepared to try the question in several cases, and, if necessary, he was prepared to apply to Parliament for additional powers.

The house then went into a committee of supply, and a vote of £280,800, in addition to £100,000 already voted, for the hospital establishments, was agreed to.

Correspondence.

"CONSANGUINITY."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your Correspondent "Consanguinity" asks a question which has been, and probably ever will be, the subject of dispute.

Prima facie there appears no reason why two persons *perfectly* healthy should generate disease in their offspring; but we must find two members of one family perfectly free, not only from physical and constitutional, but mental defect also; or the offspring may be expected to develop more strongly the idiosyncracies of their parents. Arguing by analogy, the laws of nature appear opposed to such unions—the lower orders of animals visibly deteriorate if limited to one stock, while crossing with other breeds improves them in every respect.

In cattle breeding especially, where this matter has been carefully studied, the improvement has been remarkable.

In the vegetable kingdom we observe similar results—land will not produce the same crops year after year in perfection.

In many parts of Great Britain, especially in some of the Western Isles, the effect upon man may be traced; perhaps some of your readers will favour you with a report.

I give you the opinion of a clergyman in charge of a valley in a northern country, 12 miles in length, containing a popula-

tion of 1800, entirely pastoral, sprung from about half-a-dozen persons.

"They are all cousins, extremely ignorant and pig-headed; the Australian aborigines are gentlemen in comparison, many of them have never seen an ear of corn growing; we have to send upwards of twenty miles for a cabbage; only one sheep is killed in a week; they all live upon porridge."

"Two clergymen and a schoolmaster have become insane during the past six years. The valley is beautiful in the summer, a charming place to go on a visit, but quite out of the civilized world."

Such is the mental condition to which they are reduced, that they make no effort to improve their position, but are sunk to a dead level of intellectual inferiority.—Yours, &c. C. G.

DR. LETHEBY'S LECTURES ON FOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would, doubtless, be a great boon to the profession, if physiologists would agree together on something as true, and stick to it; but whilst statements diametrically opposed to each other are constantly issuing from these oracles, medical men must toss up to ascertain which oracle they are to follow, a state of things quite sufficient to account for the present unsatisfactory results of medical practice. If a physician, relying on the statements of one physiologist, that a substance, considered by all other physiologists to be a poison, is a food, prescribes it to his patient, it is no wonder that his patient gets worse instead of better under such treatment; and yet this is the position that Dr. Letheby has assumed with respect to alchohol in your issue of March 4th, page 199, where he speaks of the drunkard's food as consisting mainly of "fat forming food," an observation which, if it has any meaning, must refer to the convertibility of alcohol into fat by the animal economy, a fact denied by nearly every other physiologist, including the repentant Liebig himself, who first gave currency to the statement.[1]

Again, we find Dr. Letheby stating, at page 198, that two pounds of bread without an admixture of *animal food* cannot support life in man, a statement totally untrue, if Dr. Letheby means by bread whole-meal bread, and not the unwholesome fabrication of the baker—viz., white bread,[2] which every physician and physiologist should at once banish from society. White bread and water alone will not, I admit, support animal life, though whole-meal bread and water will, but from the loose and vague manner in which Dr. Letheby has stated the matter, it is impossible to decide which kind of bread he refers to. Now, as a matter of fact, opposed to his statement (supposing him to mean brown bread), I quote the following passage from page 412 of that incomparable work, "Sylvester Graham's Science of Life," where Captain Hawland, of New Bedford, Mass., states, "I have often hired men to labour for me in Russia, which they would do from sixteen to eighteen hours, and find themselves, for 8 cents. per day (the sun shining there sometimes twenty hours a-day). They would come on board in the morning with a piece of their black bread, weighing about *a pound*, and a bunch of garlieks as big as one's fist. This was all their nourishment for the day of sixteen or eighteen hours' labour. They were astonishingly powerful and active; and endured severe and protracted labour far beyond any of my men. Some of these men were eighty and ninety years old, and yet these old men would do more work than any of the middle-aged men belonging to my ship. In handling and stowing away iron, they exhibited most astonishing power. They were full of agility, veracity, and even hilarity—singing, as they laboured, with all the buoyancy and blithesomeness of youth."

Now, as to Dr. Letheby's statement about the insufficiency of vegetable food for men required to perform heavy and laborious work, the evidence on the subject, which is ponderous in amount, is totally opposed to Dr. Letheby's ideas. The evidence against his views is so abundant and cumulative that the difficulty I find is in making a few selections from it. Adam Smith, in his "Wealth of Nations," informs us, for instance, that "the Irish chairmen, porters, and coal-heavers in London who have been raised principally on the potato, and who continue to subsist on vegetable food, are, perhaps, the strongest men in the British dominions." "Brindly, the celebrated canal engineer, informs us that in the various works in which he was engaged, where the workmen being paid by the piece, each exerted himself to earn as much as possible, men from the North of Lancashire and Yorkshire, who adhered to their customary diet of oat-cake and hasty-pudding, with water for their drink, sustained more labour, and made greater wages than those who lived on bread, cheese, bacon, and beer—the general diet of labourers in the south."

Alluding to the salt and coal-heavers in Liverpool and London, Captain Price, of New Bedford, Mass., states, "I have been surprised at their great strength and power of endurance in comparison with their simple and scanty diet. Their food consists principally of oatmeal and other coarse bread, and cheese, dining on about four ounces of coarse bread, and two or three ounces of cheese. On one occasion two of these men came alongside of my ship with a boat-load of salt for me, and *one* of them actually *threw* that salt with a shovel *up nine feet on to the deck* of my ship as fast as *two* of *my men could throw it into the hold*."

The following case may be cited as the result of a direct comparison between the effects of animal and vegetable food in enabling men to endure protracted and severe exertion:—

"Thomas McGoodin, a man about 40 years old, small frame, and weighing 130 lbs., was induced from religious considerations (nine years previously) to abandon the use of animal food, and adopt a simple vegetable and water diet, when a competition arose in the beetling department of the factory in which he was engaged, in which the ability of the labourers to endure powerful and protracted effort was severally tried. Two stations requiring precisely the same exertion were to be occupied for several days in succession. McGoodin was assigned one of them, and occupied it through the whole time without flagging in the least; while the other station was *successively* occupied by three or four of the strongest men in the establishment, all of whom were actually tired out, and obliged to be relieved. The overseer declared that he believed McGoodin would kill every man in the establishment if they were obliged to hold their way with him till he gave out. McGoodin also laboured from one to two hours a-day longer than any other man."—Sylvester Graham, page 419.

"The Polish and Hungarian peasants from the Carpathian Mountains, 'says a young Polish nobleman,' are among the most active and powerful men in the world; they live almost entirely on oatmeal bread, and potatoes. The Polish soldiers under Bonaparte would march forty miles in a day, and fight a pitched battle, and the next morning be fresh and vigorous for further duties."—Sylvester Graham, page 401.

As regards animal food for invalids, Dr. Cheyne says, "For those who are extremely broken down with chronic disease, I have found no other relief than a total abstinence from all animal food, and from all sorts of strong and fermented liquors. In about 30 years' practice in which I have advised this practice, I have had but *two* cases in whose total recovery I have been mistaken, and they were both too deeply diseased and too far gone for recovery before I undertook with them."

Knowing, sir, the mischief that arises in the treatment of disease from the erroneous supposition of medical men regarding the nutritious effects of vegetable and farinaceous food, I have felt compelled by a sense of duty to humanity thus to come forward and combat the mischievous doctrines propounded by Dr. Letheby. Against that gentleman I have no animus of any kind, but feel strongly opposed to the principles he promulgates. There is no more potent source of disease, in my mind, than overfeeding, and especially over-indulgence in animal food—an indulgence which a belief in his doctrines would tend to increase and perpetuate. The prescription of meat and stimulants of every kind to invalids is well-known

1 The researches of the most eminent chemists and physiologists all combine in showing that alcohol is a *poison*, and unassimilable by the system, which it leaves in the same form as it entered it, causing by its expulsion a waste of vitality. Dr. Trall states that he never saw anything but evil result from its use in disease, and improvement always to follow its disuse. Respecting the erroneous belief in alcohol, Dr. Carpenter has well observed:—"The whole medical art is based upon *experience*, and the value of any remedy *can only be fairly tested* by the *omission* of it in some of the cases in which it has been reputed to be *most successful*. Nothing can be stronger than the reputation which alcoholic stimulants have acquired, as affording efficient aid in the maintenance of the bodily strength under circumstances calculated to exhaust it; and yet the most unimpeachable testimony has shown the fallacy of this opinion, and put *universal* experience *quite* in the wrong. So it has sometimes, nay, often, happened that medical men have assured staunch teetotallers that they would die unless they admitted alcohol into their system as a medicine; but *the patients, being obstinate, did neither, thus* falsifying the prediction in a very unexpected measure, and proving that the experience of doctors is not more infallible than that of the public."

2 The cause of white bread not supporting animal life, is the same as that which causes the death of cattle, if fed exclusively on corn, without the addition of hay—viz., too highly concentrated nutriment, and the absence of the woody or indigestible element. Bulk, or a duly diluted nutriment is an essential condition of every form of food. How little is this fact recognized or acted on in practice?

to be highly injurious by all those who have had experience of treating them without them, as delaying recovery, and tending to exhaust vitality. For ample evidence on this subject I would refer the reader to "Sylvester Graham's Science of Life," and the various and manifold works of Dr. R. T. Trall, of New York. Apologising for trepassing thus far on your space, the importance of my theme being my only excuse, I remain, sir, your obedient servant,

RICHARD GRIFFITH, Ch.M.

St. Anne's Hill, Cork.

Medical News.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK.—The twentieth anniversary festival of this charity was celebrated at the London Tavern, on Wednesday the 26th, Lord Feversham, one of the vice-presidents of the institution, in the chair, supported by the Sheriff of London and Middlesex, Messrs R. N. Fowler, Tucker, F. A. Bevan, and others. The report showed that the number of patients treated in the hospital during the year 1867, amounted to 582, of these 522 were more or less relieved, and 60 died. The total of out-patients treated during the year amounted to 14,210, and the whole number treated since the opening of the hospital in 1848, now numbered 141,791. The noble chairman made a forcible appeal to the liberality of the public, on behalf of this hospital, which relieves so many of the poor in the East of London, and set a splendid example by himself contributing £100 to the funds; other donations and subscriptions came in freely and generously, and, in the course of the evening, the sum of £2800 was announced by the Hon. Secretary (Mr. Sewell) as having been received. The medical staffs of the hospital were represented in the persons of Drs. Peacock, Bennett, Birkett, Ward, Thorowgood, Fenwick, Baumler, and Rickards. The toast of the medical officers was responded to by Dr. Ward, in an able speech.

STATISTICAL SOCIETY. — Thirty-fourth Annual Meeting.—Council and Officers for 1868-69 (those marked *a* are new members). President—The Right Honourable W. E. Gladstone, M.P. Council—*a*H. W. Acland, M.D., F.R.S.; Walter Bagehot, M.A.; Major-General Balfour, C.B.; *a*Thomas Graham, Balfour, M.D., F.R.S.; R. Dudley Baxter, M.A.; Lord Belper; Sir John Boileau, Bart., F.R.S.; Samuel Brown; William Camps, M.D.; *a*Hyde Clarke, D.C.L.; Leonard Henry Courtney; William Farr, M.D., D.C.L., F.R.S.; William Augustus Guy, M.B., F.R.S.; James Thomas Hammick; Frederick Hendriks; James Heywood, M.A., F.R.S.; William Barwick Hodge; Right Hon. Lord Houghton; Francis Jourdan; John Lambert; Leone Levi; *a*Sir John Lubbock, Bart., F.R.S.; William Golden Lumley, LL.M.; *a*Sir James Ranald Martin, C.B., F.R.S.; William Newmarch, F.R.S.; Frederick Purdy; Rev. J. E. T. Rogers, M.A.; *a*Alderman Solomans, M.P.; Colonel W. H. Sykes, M.P., F.R.S.; and Jacob Waley, M.A. Treasurer—James Thomas Hammick. Honorary Secretaries—William Augustus Guy, M.B., F.R.S; William Golden Lumley, LL.M.; and Frederick Purdy.

THE Royal Commission on Water Supply held their meeting at the House of Lords, on the 25th and on the 26th inst. Present—Sir John Thwaites, in the chair; Colonel Harness, R.E., C.B., Sir Benjamin Phillips, Thomas E. Harrison, Esq., C.E., Joseph Prestwich, Esq., F.R.S.; and the Secretary, Mr. W. Pole, F.R.S.

LONDON GAS.—The medical officer of health, for the city of London, has issued a report on the qualities of the gas during the past 12 months, and as London gas has been for some time the occasion of an exciting controversy, we avail ourselves of his labours to publish a few of the facts he has reported. He made 2677 examinations of the gas during the period in reference to its illuminating power. The chymical quality of the gas had been subject to great variation; in fact, of 659 experiments that had been made to determine the proportion of sulphur in the gas supplied to the city during the year, there were 263 occasions when the quantity of that impurity was in excess of the amount sanctioned by Parliament. The results of the experiments showed that occasionally for three months together the quantity of sulphur in the gas of each of the companies had been comparatively small, and then for months again it had been excessive. This shows that there is great irregularity in the manufacture and purification of the gas. Taking the average of the whole year, the amount of sulphur in the gas had not been in excess of the quantity sanctioned by Parliament, but the fluctuations had been excessive. Of the 220 examinations made of the Great Central Gas there were 71 occasions when the quantity of sulphur was more than the Act sanctions. Of the 219 examinations of the Chartered Gas 92 were in excess of it, and of the 222 of the City Company's Gas 100 were in excess. Altogether, the failures to comply in this respect with the requirements of the Act of Parliament amounted to nearly 40 per cent., but in the three preceding years it averaged 56 per cent. There was, therefore, some improvement in that particular; and if the present practice of the Great Central Company in using lime for the purification of the gas be carefully followed out, as Mr. Hawksley and Dr. Letheby had recommended, the quantity of the sulphur in the gas would, no doubt, be kept, as it now was, under the amount sanctioned by Parliament. Sulphuretted hydrogen, another impurity, had always been absent from the gas of each of the companies; but as regarded ammonia the proportion had constantly been excessive in the Chartered Gas, and occasionally so in the Great Central.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The following *urgent* cases have been relieved during the month of March:—

1. A medical man, aged 39, Kingstown, M.R.C.S.E. and L.A.H.I. Far advanced in phthisis, has a wife and seven children, all young, and no means of support. 1st application. Recommended by Drs. Barton, Hudson, and Smyly. Granted for immediate necessities £10.

2. A medical man, aged 53, Co. Galway, M.R.C.S.E., has lost, under circumstances of peculiar hardship, a public appointment, which he held for 26 years; has a very delicate wife. A small annuity, which has been handed over to pay his debts. 1st. application. Recommended by Drs. Adams, Johnston, Denham, and Elliott. Granted for immediate necessities £10.

3. A widow, aged 44, Dublin. Husband, M.R.C.S.E., lost at sea when proceeding to America. Two sons, one in Canada, the other in Australia, and a daughter now dying of phthisis; for some years maintained herself with the assistance of friends, now dead. Granted last year two sums of £5. Recommended by Drs. Collis and Mason. Granted for immediate necessities £5.

NOTICES TO CORRESPONDENTS.

Dr. DAVEY, Bristol, is thanked for his communication.

Dr. WEBSTER, Bristol.—The glasses may be had on application to Messrs. Fannin and Co., Surgical Instrument Makers, 41, Grafton-street, Dublin.

Dr. RAMSDEN, Staithwaite.—Mr. Berkeley Hill's book on "Bandaging" is published by Mr. Walton, Gower-street.

A SUBSCRIBER retiring from practice is anxious to dispose of an articulated skeleton, some surgical instruments, books, &c. Amongst the latter are "Braithwaite's Retrospect" and the publications of the new Sydenham Society from the commencement; the *Medical Circular*, bound, from 1854, and the *Medical Press* since its incorporation in 1866. Particulars can be obtained on application to the London Office of this paper.

M. B.—There is an old maxim respecting "What is bred in the bone, &c.," which is very applicable in the present case. There can be no doubt of the ability and energy of the person named; having, however, the distinguishing characteristics of the "Ancient People," the practices are scarcely surprising.

Several letters are unavoidably held over for want of space.

BOOKS, PAMPHLETS, &c., RECEIVED.

Report of the Medical Officer of Health for the Limehouse District.

Dr. LETHEBY'S THIRD LECTURE ON FOOD.

CONSTRUCTION OF DIETARIES: PREPARATION AND CULINARY TREATMENT OF FOODS.

(Continued from page 260).

In associating different articles of diet, so as to secure the right proportions of the several constituents of food—fat, sugar, or starch, and nitrogenous matter, we find that we may not only rely on the sound indications of science, but may also trust, and trust safely, to the unerring guidance of our instincts—provided they have not been vitiated by fashion or perverted by evil habits. Science teaches us that the best proportions for the common wants of the animal system are about 9 of fat, 22 of flesh-forming substances, and 69 of starch and sugar; and experience also shows that these are the very proportions which we are constantly striving to maintain in our daily dietaries. Borrowing largely from the graphic illustrations of Liebig and Johnston, I may state that, whenever one kind of food is wanting in any particular constituent we invariably associate it with another that contains an excess of it. Certain meats, for example, which are deficient of fat are always eaten with substances that are rich in it—bacon is associated with veal, with liver, and with fowl, or we capon the latter, and thus increase its natural fat. We use melted butter with most kind of fish, or we fry them in oil; while the herring, the salmon, and the eel, are usually fat enough in themselves, and are dressed and eaten alone. It is with a view to similar adjustment that we mix eggs and butter with sago, tapioca, and rice; that we add oil and the yoke of an egg to salad; that we boil rice with milk, and eat cheese with maccaroni. The same instinct has determined the use of vegetables with meat, and butter with bread. Bacon and greens, or beans and bacon, like pork and peas-pudding, is a conjunction of viands which does not owe its popularity to old habit or the mere taste of the epicure; and so with a dish, common in Ireland, under the name of Kol-cannon—the potatoe, which is poor in gluten, and the cabbage, which is usually rich in this ingredient, are mixed together, and thus they approach the composition of wheaten bread, but both of these substances are deficient in fat; add, therefore, a little bacon or fat pork to the mixture, and you have a Kol-cannon, which has all the good qualities of the best Scotch oatmeal, and to many it is more savory and palatable. Again, the mixture so usual in Ireland and Alsace, of butter-milk or curdled milk and potatoes, and the combination of rice and fat which makes the diet of eastern nations; even the little dab of butter upon the poor man's potatoe, and the bit of cheese that he eats with his bread for dinner, are matters not of luxury but of necessity, and they show how by long experience we have at last learnt to adjust the proximate constituents of food, so as best to maintain the health and vigour of the body.

And then again, the times for taking food, and the proper distribution of it in appropriate meals are questions of considerable importance, notwithstanding that they have ever been influenced by the caprices of fashion, and the artificial habits of society. How much they have had to do with the modifications of the human species, and even with the extinctions of whole races of men is an etiological problem of much interest.

Man in his savage condition feeds with great irregularity, for when he finds that food is plentiful he eats from morning to night, and knows no other pleasure than that of eating and drinking and sleeping; but when it is more scarce he is content with a single meal a-day. In both cases, however, the quantity of food consumed is excessive. We are told by travellers that the Hottentots, the Bushmen, and the inhabitants of Southern Africa, who feed in this manner are enormous gluttons—ten of them, says Barrow, ate in his presence a middling sized ox, all but the hind legs, in three days; and the three Bosjesmen that accompanied his waggon, devoured a sheep on one occasion in less than 24 hours. Captain Parry also, with Ross and others, have given the most astonishing accounts of the dietical capabilities of the Esquimaux. Captain Parry once tried the capacity of a young lad scarcely full grown, and in 24 hours he had eaten 4 lb. 4 oz. of the raw hard-frozen flesh of a sea-horse, the same quantity of it boiled, 1 lb. 12 oz. of bread and bread-dust, besides a pint and a quarter of rich gravy soup, a tumbler of strong grog, three wine glasses of raw spirits, and nine pints of water. According to Sir John Ross, the daily rations of an Esquimaux are 20 lbs. of flesh and blubber. But the most marvellous example of gluttony is given by Captain Cochrane, on the authority of the Russian Admiral Saritcheff, who was told that one of the Yakuti had consumed the

hind quarter of a large ox in 24 hours, together with 20 lb. of fat, and a proportionable quantity of melted butter. To test the truth of this, he gave him a thick porridge of rice boiled down with 3 lbs. of butter, weighing together 28 lbs.: —although the glutton had already breakfasted, yet he sat down to the meal with great eagerness, and consumed the whole of it without stirring from the spot; and except that his stomach betrayed more than ordinary fulness, he showed no sign of inconvenience. Captain Cochrane further adds that a good calf weighing 200 lbs. will just serve for a meal for four or five Yakuti; and that he has himself seen three of them consume a rein-deer at a meal. Liebig accounts for this by saying that a nation of hunters, especially when they go naked and are exposed to great losses of temperature, must consume large quantities of respiratory food; and if it so happens that the food is in its least effective form, as lean flesh, the quantity disposed of is enormous.

Among civilized nations, and until comparatively recent time, there were but two meals a-day—namely dinner and supper. These were the meals of the Romans—the *prandium* or dinner being for the most part a light refreshment eaten while standing, at about 9 o'clock in the morning; and it generally consisted of the cold remains of yesterday's supper. It was commonly taken without wine, and in fact there was so little ceremony about it, that Plautus in his comedies, has facetiously called it *caninum prandium*. The great meal of the day was the supper or *cœna*, which was taken about 3 or 4 o'clock in the afternoon, and to which friends were invited. This was the ceremonious meal for which the wealthy and high families of Rome exhausted the resources of luxury and art. It always consisted of three parts—the *gustus* or antipast, which was intended as a mere smack or relish to wet the appetite. Then came the main part of the feast—consisting of many courses, with a chief dish or *caput cœna*; and when in thrifty families it was the only dish which went the round of the frugal board, it was aptly termed the *cœna ambulans*. After this there came the second course or *mensa secunda*, composed of fruits and pastry like a modern dessert.

The sums of money expended by the wealthy Romans on this meal were often ruinous. Vitellius is said to have spent as much as 400 *sestertia* (about £3228 of our money) on his daily supper; and the celebrated feast to which he invited his brother Lucius, cost no less than 5000 *sestertia* or £40,350 sterling. It consisted, according to Suetonius, of 2000 different dishes of fish, and 7000 of fowls, with other equally numerous meats. His daily food, says our classical writers, was of the most rare and exquisite nature, the deserts of Libya, the shores of Spain, the waters of the Carpathian sea, and even the forests and coasts of Britain, were diligently searched for dainties to supply his table; and had he reigned long, he would, says Josephus, have exhausted the great opulence of the Roman Empire. Ælius Verus, another of those worthies, was hardly less profuse in the extravagance of his suppers; for it is said that a single entertainment, to which only about a dozen guests were invited, cost above six million sesterces (6000 *sestertia*, or nearly £48,500); and we are told by historians that his whole life was wasted in eating and drinking—being spent in the voluptuous retreats of Daphne, or else at the luxurious banquets of Antioch. So profuse, indeed, was the extravagance of those times, that to entertain an Emperor at a feast was to encounter almost certain financial ruin—one dish alone at the table of Heliogabalus has been known to cost about £4000 of our money; no wonder, therefore, that these imperial feasts were lengthened out for hours together, and that every artifice, often revolting in the extreme, was used to prolong the pleasure of eating, or that Philoxenus should have wished that he had the throat of a crane with a delicate palate all the way down.

Hardly less extravagant were the dining propensities of our own forefathers, who in every way copied too closely the luxurious habits of their Roman conquerors. In fact, no circumstance, as Mr. Wright observes, is more remarkable in ancient history, than the readiness with which the people who came under the sway and influence of Rome, abandoned their nationality and followed the luxurious habits of their rulers. Even so late as the time of Holinshed, the famous chronicler of the 16th century, the manners of the English were the subject of severe comment; for he tells us that "in number of dishes, and changes of meat, the nobility of England (whose cooks are, for the most part, musical-headed Frenchman and Foreigners) do most exceed; sith there is no day in manner that passeth over their heads, wherein they have not only beef, mutton, veal, lamb, kid, pork, cony, capon, pig, or so many of these as the season yieldeth, but also some portion of the red and fallow deer, beside great variety of fish and wild fowl, and thereto sundry other delicates, wherein the sweet hand of the sea-faring Portingale is not wanting; so that, for a man to dine with one of them, and to taste of every dish that standeth before him, is rather to yield unto a conspiracy, with a great deal of meat for the speedy suppression of natural health, than the use of a necessary meal to satisfy himself with a competent repast to sustain his body withal." He adds, too, "that gentlemen and merchants keep much about the same rate; and when they make their ordinary or voluntary feasts, it is a world to see what great provision is made of all manner of delicate meats from every quarter of the country, wherein, beside that, they are often comparable herein to the nobility of the land; so that they will seldom regard anything that the butcher usually killeth, but reject the same as not worthy to come in place. In such cases, also *geliffes* of all colours, mixed with a variety in the representation of sundry flowers, herbs, trees, forms of beasts, fish, fowls, and fruits; and there unto *marchpane* wrought with no small curiosity, tarts of divers hues, and sundry denominations; conserves of old fruits, foreign and home-bred; suckets, codiniacs, marmalades, sugar-bread, ginger-bread, florentines, wild-fowl, venison of all sorts, and sundry outlandish confections, altogether seasoned with sugar, besides infinite devices, not possible for me to remember."

The learned Caius, also, in his counseill against the sweat of the same century (1552) comments in severe terms on the gluttony of his time, saying that the reason why the disease attacks the English more than others is that they have "so moche sweating stuffe, so many euille humoures laid up in store, fro this displeasante, feareful, and pestilent disease, cause of their euille diet, whiche destroy more meates and drynckes withoute al ordre, conenient time, reason, or necessite, the either Scotlande or al other countries under the sunne."

Gradually, too, as the dinner got to be later in the day, and reached noon-time, there was necessity for a light early meal, or *breakfaste*, as it was called; and as the dinner became later and later still, a fourth meal was added—the *lunch* or *luncheon*, which literally meant a slice of bread. In process of time, also, with the introduction of tea and coffee into England, there came a fifth meal; but all along the dinner was the great feast of the day; and the rule in using it was pretty much as Dr. Kitchener in his time advised—namely, to eat until there was a sense of satiety, the stimulus of every fresh dish being but as a whip to the appetite, so that the sense of satiety might come and go a dozen times. "It is produced in us," says Christopher North, "by three platefuls of hotch-potch, and to the eyes of an ordinary observer our dinner would seem to be at an end; but no; strictly speaking, it is just going to begin. About an hour ago did we, standing on the very beautiful bridge of Perth, see that identical salmon, with his back-fin just visible above the translucent tide, arrowing up the Tay, bold as a bridegroom, and nothing doubting that he should spend his honeymoon among the gravel-beds of Kinnaird or Moulenearn, or the rocky sofas of the Tummel, or the green marble couches of the Tilt. What has now become of the sense of satiety? John—the castors!—mustard—vinegar—cayenne—catchup—peas and potatoes, with a very little butter—the biscuit called "rusk"—and the memory of the hotch-potch is as that of Babylon the Great." Sense of satiety indeed!—"We have seen it for

a moment existing on the disappearance of the hotch-potch —dying on the appearance of the Tay salmon—once more noticeable as the last plate of the noble fish melted away—extinguished suddenly by the vision of the venison—again felt for an instant, and but for an instant, for a brace and a-half of as fine grouse as ever expanded their voluptuous bosoms to be devoured by hungry love."

We smile at the accounts given of the gormandizing powers of the natives of Arctic regions and the savages of Southern Africa, but our own habits in eating and drinking are scarcely less preposterous. Look at a modern dinner: beginning with soup, and perhaps a glass of cold punch; to be quickly followed by a piece of turbot or a slice of salmon with lobster-sauce; and while the *caput cœnæ*, the venison or South Down, is getting ready, we toy with an oyster patè or a bit of sweet-bread, and mellow it with a bumper of Madeira. No sooner is the venison or mutton disposed of, with its never-failing accompaniments of jelly and vegetables, than we set the whole of it in a ferment with champagne, and drown it with hock or sauterne. These are quickly followed by the wing and breast of a partridge, or a bit of pheasant or wild duck; and when the stomach is all on fire with excitement, we cool it for an instant with a piece of iced pudding, and then immediately lash it into a fever with undiluted alcohol, in the form of cognac or a strong liqueur; after which there comes a spoonful or so of jelly as an emollient, a morsel of ripe stilton or paté de foie-gras as a digestant, a piquante salad to wet the appetite for wine, and a glass of old port to persuade the stomach, if it can, into quietness. All these are more leisurely succeeded by the *mensa secunda*, or dessert, with its ices, its preserves, its bakemeats, its fruits, its geliffes, codiniacs, and suckets, as Holinshed would call them, and its strong drinks; to be afterwards muddled with coffee, and complicated into a rare mixture with tea, floating with the richest of cream.

As a modest example of this sort of thing, and an indication moreover of the kind of novelties yet in store for us, let me read to you the *menu* of a late dinner at the Langham, where horse-flesh was the principal *viande*. It is very appropriately prefaced with a little bit of French philosophy—"*Les préjugés sont des maladies de l'esprit humain.*

"*Potages*—Consommé de cheval. A la purée de destriers. *Amontillado.*

"*Poissons*—Saumon à la sauce Arabe. Filets de soles à l'huile hippophagique. *Vin du Rhin.*

"*Hors-d'œuvres*—Terrines de foie maigre chevalines. Sancissons de cheval aux pistaches syriaques. *Xérès.*

"*Relevés*—Filet de Pégase rôti aux pommes de terre à la crême. Dinde aux châtaignes. Aloyau de cheval farci à la centaur e aux choux de Bruxelles. Culotte de cheval braisée aux chevaux-de-frise. *Champagne sec.*

"*Entrées*—Petits pâtés a la moëlle Bucéphale. Kromeskys à la Gladiateur. Poulets garnis à l'hippogriffe. Langues de cheval à la Troyenne. *Chateau Perayne.*

"SECOND SERVICE.

"*Rots*—Canards sauvages. Pluviers. *Volney.* Mayonnaises de homard a l'huile Rossinante. Petits pois a la Française. Choux-fleurs au parmesan.

"*Entremets*—Gelée de pieds de cheval au marasquin. Zephirs sautés à l'huile chevaleresque. Gateau vetérinaire a la Ducroix. Feuillantines aux pommes des Hesperides. *St. Peray.*

"*Glaces*—Crème aux truffes. Sorbets contre-préjugés. *Liqueurs.*

"*Dessert*—Vins fins de Bordeaux. Medère. Café.

"*Buffet*—Collared horse-head. Baron of horse. Boiled withers."

Even put into plain English all this would sound remarkable, and taken, as it is said to have been, without shying or gibbing, although, perhaps, with a little bolting, it must have puzzled the stomach; and, like all our modern dinners, must also have severely taxed its powers, in selecting from the complicated mess, the right proportions of fat and flesh, and farinaceous matter required for the sustenance of the body.

Nor is it right to content ourselves like savages, with a single meal a day, as was the custom of Dr. Fordyce, the celebrated Professor of Chemistry of the last century. Studying the habits of carnivorous animals, and reflecting on the principles of chemistry and physiology, he came to the conclusion that man required but one meal a day for all his physiological wants; and for more than twenty years his daily dinner was as follows:—Regularly at four o'clock of an afternoon, he would present himself at "Dolly's chop-house," and take his seat at the table reserved for him. Immediately on his arrival the cook would place a pound and a half of rump-steak upon the gridiron, and while it was cooking the doctor would amuse himself with some such trifle as half a broiled capon, or a plate of fish, and a glass or two of brandy—his regular allowance being a quarter of a pint. Then came the steak with a full accompaniment of bread and potato, and it was always served with a quart tankard of strong ale. This was followed by a bottle of old port; and, when the dinner was finished, as it invariably was in an hour and a half, he walked leisurely to his rooms in Essex-street in the Strand, where punctually at six o'clock he met his class and gave his lecture on chemistry.

But these are not the habits of the great bulk of mankind, and although they may have been practised for a while with impunity, yet they serve not as illustrations of what ought to be done in the way of eating, but rather as examples of the wonderful accommodating power of the stomach under the most disadvantageous circumstances; for experience teaches us that three meals a day, of the simplest quality, are best suited for our wants—breakfast to supply the want of long fasting, and to restore the waste of secretion during the night; dinner in the middle of the day to support the system during the fatigue of ordinary labour; and a light meal at night, in the form of tea or an early supper, to carry on the functions of repair and secretion during the night. According to Dr. Edward Smith, the daily distribution of the food, supposing a physiological diet of 4300 grains of carbon, with 200 grains of nitrogen to be taken, should be somewhat in this manner:—

	Carbon. grs.	Nitrogen. grs.
For breakfast	1500	70
For dinner	1800	90
For supper	1000	40
Total in the day	4300	200

So that about one part should be eaten for supper, one and a-half for breakfast, and about two parts for dinner.

It is hardly necessary to say, that in constructing dietaries, the foods should be associated in such a way as not to offend the appetite or burden the digestive powers; and that they should, also, be varied from time to time, not merely in their kind, but also in their treatment, as in the manner of cooking and flavouring them; for the best descriptions of food will, if eaten in the same fashion day after day, occasion disgust, and be wasted. This is often the case in the badly arranged dietaries of workhouses, and on ship-board. It was once so with the dietaries of the English army, when the same daily rations of boiled meat were provokingly served out to the men, while they listened to the tune of "Oh the roast-beef of old England." All this is easily provided for, and it is true economy to do so, by varying the food, the mode of cooking it, the manner of flavouring it, and by serving it, in the case of dinner, with different kinds of vegetables.

In constructing dietaries, therefore, the main considerations are the due supply of the right proportions of nitrogenous and carbonaceous matters; for when these are not adjusted in a proper manner, the health is endangered, and the constitution may be slowly undermined. To use the words of Liebig—"there is a law of nature which regulates these things, and it is the elevated mission of science to bring this law home to our minds; it is her duty to

show why man and animals require such admixture in the constituents of their food for the support of the vital functions, and what the influences are which determine, in accordance with the natural law, changes in the admixture.

"'The knowledge of the law elevates man in regard to an important function which he possesses in common with the lower animals, above the level of those beings which are destitute of reason, and supplies him, in the regulation of those bodily wants which are essential to his existence and prosperity, with a protection which the lower animals do not require, because in them the commands of the instinctive law are not opposed or over-powered by the allurements of sense or by a perverted and resisting will.'"

The recognition of this law, and the practical application of it to the dietaries of a community, are obviously of great advantage, for not only would they tend to increase the health and strength of the population, but they would also effect a great economy in the general use of food. That there are difficulties in the way of such an application cannot be doubted; in fact, the natural peculiarities of individuals, to say nothing of the differences of occupation, and the ever varying quality of the food itself, are enough to create a doubt as to the possibility of its general application until the progress of science has gone far beyond its present position. Nevertheless, there are certain well-acknowledged facts at our disposal which may safely serve as a guide to practice.

The diseases which are incidental to an abuse of the law can hardly be discussed in this place, but it may be said in general terms, that too much or too little of either of the main constituents of food will soon be followed by marked derangements of the animal body. An excess of respiratory food not only promotes the growth of fat, but actually interferes with the nourishment of muscular tissue. Those who feed largely on rice, on potatoes, or other farinaceous foods, or who indulge too freely in malt liquors, have commonly a bloated appearance, and have no faculty for sustained exertion. The brewer's drayman, for example, is a bad subject for the ward of a hospital; and although he sometimes looks strong and muscular, yet in reality his vital power is feeble, and his tissues are fatty rather than muscular. The same is often the case with animals in the Zoological Gardens, when too large a quantity of respiratory food has been eaten, and their flesh has undergone a kind of fatty degeneration.

On the other hand, when the plastic elements of the food are in excess, the system becomes excited, too much blood is formed, and diseases of a plethoric character are induced. According to Liebig and his followers, an excess of force is developed, which manifests itself in irritability of temper, and in a savage disposition. How far this may be concerned in the frequently ungovernable conduct of our over-fed convicts may be deserving of consideration. A nation of animal *feeders*, says Liebig, is always a nation of hunters, for the use of a rich nitrogenous diet demands an expenditure of power, and a large amount of physical exertion, and this is seen in the restless disposition of all the carnivora of our menageries.

A deficiency of food, however, is quickly followed by a general breaking up of the animal frame. Plague, pestilence and famine, are always associated in the public mind; and the records of every country show how closely they are related. The medical history of Ireland is remarkable for illustrations of how much mischief may be occasioned by a general deficiency of food. Always the habitat of fever, it every now and then becomes the very hot-bed of its development. Let there be but a small failure in the usual imperfect supply of food, and the lurking seeds of pestilence burst into frightful activity. The famine of the present century is but a too forcible illustration of this, for it produced epidemics which had not been witnessed in this generation, and it gave rise to scenes of devastation and misery which are not surpassed by the most appalling of the middle age. The principal form of the scourge was known as the contagious famine fever, and it spread, not merely from end to end of the country in which it had originated, but, breaking through all boundaries, it crossed the broad ocean, and made itself painfully manifest in localities where it was previously unknown. Thousands fell under the virulence of its action, for wheresoever it came it struck down a seventh of the people, and of those whom it attacked one out of nine perished. Even those who escaped the fatal influence of it were left the miserable victims of scurvy and low fever. Another example, not less striking, of the terrible consequences of what may be truly called famine, was the condition of our troops during the early part of their sojourn in the Crimea—with only just enough of food to maintain the integrity of the system at a time of repose, and at ordinary temperatures, they were called upon to make large muscular exertions, and to sustain the warmth of the system in the midst of severe cold. What could be expected but that the scourges which wait upon famine, as fever, diarrhœa, dysentery and scurvy, should make their appearance in great force, and that the soldiers should perish by thousands. With an average strength of 24,000 men, the deaths from sickness alone, in the course of seven months, were at the rate of thirty-nine per cent., and in some cases it amounted to seventy-three. "Never before," says Colonel Tulloch, "is there record of a British army having sustained so frightful a loss in so short a time." During the Peninsular War, though the troops occasionally suffered much from sickness, the loss from that cause did not average above twelve per cent. for a whole year. Even in the ill-fated expedition to Walcheren, which threw the nation into mourning, the deaths amounted to only about 10½ per cent. for the half year; and here, in this great city, with all the aggravating circumstances of want, vice, infancy, old age and disease, it did not reach to two per cent. during the time that our strong men were dying by thousands. "Armies have perished by the sword, and have been overwhelmed by the elements, but never, perhaps," says Colonel Tulloch, "since the hand of the Lord smote the host of the Assyrians, and they perished in a night, has such a loss from disease been recorded as on this occasion." May the lesson of so great a calamity be wisely applied to the future profit of the country!

The connection of scurvy with improper or insufficient food is a matter of medical history, and its prevention by the use of fresh vegetables, especially potatoes, is so well known that it has often been the subject of legislation. Rarely appearing in the cabin, where the dietary is good, it is a frequent visitor to the forecastle; so that half the men of our sea-going vessels are found to be suffering from the disease when they return to port. As many indeed as 70 per cent. of a ship's crew are not unfrequently disabled by it; and there is no saying how much of the disasters at sea is caused by the inability of the men to work the vessel in times of severe weather. The legal supplementary allowance in emigrant vessels of 8 oz. of preserved potatoe, 3 oz. of other preserved vegetables (carrots, turnips, onions, celery, and mint), besides pickles, and 3 oz. of lemon juice for each person weekly, is found to be a perfect prophylactic of the disease, so that the one essential cause of it is evidently a privation of vegetable food.

And not less important are the morbific results of too much or too little saline matter in the food. I have already spoken of the salutary effect of certain calcareous salts in the water we drink; but according to Dr. Grange the presence of magnesian salts in the water of a district may have something to do with the development of those remarkable forms of disease which are known as goitre and cretenism. In France, Germany, England, and Sardinia, among all classes of people of all habits, and in every variety of climate, those diseases are endemic, where the soil is composed of magnesian rock, and the water charged with magnesian salts. How far the connection extends is a chemico-physiological problem that has yet to be determined.

(To be continued.)

A CLINICAL LECTURE ON THE AVOIDANCE OF AMPUTATION IN CERTAIN CASES OF SEVERE INJURY.

By JONATHAN HUTCHINSON, F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL AND LECTURER ON SURGERY.

GENTLEMEN—Cases in which important operations have been recommended and not performed, are always of great importance in their teaching, as regards the management of others which may occur in the future. This remark especially applies to those in which the amputation of a limb or the excision of a large joint has been the measure in prospect. To some of these I now invite your attention.

In November, 1865, we admitted a young man named Piggott, a railway porter, who had had his right foot crushed by the fall of a piece of timber. Both tibia and fibula were fractured, the tibia being much comminuted. Synovia escaped freely from a wound on the outer side of the ankle-joint. There were several other wounds and the soft parts were very much bruised. The foot was somewhat twisted but the displacement was not very great. You will see then that we had to deal with one of the most serious forms of compound fracture of the leg, that, namely, in which the ankle-joint is also involved. We decided, however, considering the man's youth and his good health, to attempt to save the limb. The wounds were covered with lint soaked in blood, and with collodion applied over it.

Inflammation of the cellular tissue of the limb and of the ankle-joint followed. We were obliged to remove the dressings within a day or two, and during the next two months we had to encounter that condition of diffuse suppuration of all the parts involved, which so often either necessitates a secondary amputation or causes the patient's death. Several times during this period the propriety of amputation was discussed, and that measure was almost decided upon. On one occasion in consultation with Mr. Adams, we both agreed that it would be necessary, but decided to wait a few days in the hope that the man might be in a more favourable condition. Meanwhile, we continued the usual measures of treatment, free incisions wherever abscesses presented themselves, a poultice to the part, and as good a diet as the man could take. Mr. Colquhoun, the dresser of the case, was indefatigable in his attention to it, and to his care I have no doubt that the ultimate result was to a large extent due.

By slow degrees the condition of things improved. The accident was on Nov. 7, and a month later he was able to eat well and was in every respect gaining ground. His pulse was still, however, upwards of 120. During the early part of January I removed several considerable fragments of bone, which had become loose, and on March 15, another large portion was taken away. On the 12th of April, just four months after his admission, he was able to leave the Hospital and return to the country. A year later he came to me to show his leg, and I will now give you the particulars of his present condition.

April 2, 1867.—*Present condition.*—He is in good health and with a thick heeled boot walks fairly. He can walk two miles or more at a time, and has no pain in the leg. It is soundly healed and has been so for some months. There is some deformity, the foot and lower portions of the bones of the leg being displaced outwards, and the lower end of the upper fragment of the tibia projecting beneath the skin. His heel is about an inch and a-half from the ground. I think the ankle-joint is stiff but he has some motion in the tarsus, which might easily be supposed to be at the joint itself.

Not only is the limb now very useful but there is every reason to believe that it will improve as time passes.

Our next case for mention is that of a man whom most of you will remember in one of the attic wards about a-year ago. He was long under treatment, and at one time his arm looked almost hopeless as regards recovery.

Joseph Shephard, aged 51, a labourer from Enfield, was admitted on the 6th of November, 1865, having had his right arm crushed under the wheel of a loaded waggon. The humerus was broken at its middle, and the soft parts were severely lacerated and contused. General inflammation of the limb followed, with extensive sloughing of the skin. Splints were out of the question, and we had to manage the fracture as well as we could, suspending the limb from a cradle. The upper fragment was much displaced outwards, and to secure apposition the limb had to be carried out at right angles with the body. Mr. Colquhoun, the dresser of the case, paid it great attention. For some time I was afraid that we should be compelled to amputate, and next when things had improved somewhat there seemed much reason to fear non-union. After the bones had stiffened somewhat, erysipelas occurred, and they became quite loose again. The poor fellow was confined to bed from November 6th to May 6th, and when, at the latter date, we sent him home he was but just able to get up. The fracture was not firm, and the wounds had scarcely healed.

A year later I wrote to him to come up for inspection, and was much pleased to find him in good health, and with a very useful arm. The fracture is now quite firm, and there is but little over-lapping. In consequence of the extensive sloughing of cellular tissue, suppuration, &c., the muscles are glued down, and their motions much impeded, but the limb is still very useful to him.

Of late years I have performed exceedingly few amputations for injuries, and only when the indications have been such as to leave not the slightest doubt. The difference in risk to life between a compound fracture of the severest kind and a primary amputation seems to be very little indeed. I do not think that you diminish the liability to pyæmia at all by amputating, and this is by far the chief danger in both. Nor has the result of my experience on the whole been favourable to the performance of secondary amputations when resorted to because the patient was doing badly. I have done many such, in the hope that removal of the source of irritation would enable the system to rally, but very rarely have I met with a good result. On the other hand, of the cases which seemed hopeless, but in which for one reason or another I resolved not to amputate, every now and then, one has unexpectedly pulled through. My impression is then that we ought to regard the state of the patient's health but little in deciding on this point. If he is bearing a compound fracture badly you may infer that he will be very likely to succumb if the shock of an amputation be added. Sometimes you hear remarks made as if the loss of the limb were the only question, and as if, would the patient consent to this, the saving of his life were a certainty. In practice, however, the cases are very few in which it is really a question of life or limb, much more usually life and limb stand or fall together. One feels inclined when looking at a compound fracture which is doing badly to reason respecting amputation, much as Macbeth did as to the murder, and to say, taking a slight liberty with the text:—

> "If he were well when 't were done, then 't were well
> It were done quickly: If" &c., &c.

In thus urging you to decline for the most part the performance of secondary amputations, and to let your patient take his chance with his limb on, I do not include cases of traumatic gangrene. In most of these it is necessary to amputate as soon as the real nature of the process is clearly shown. Nor do I wish to be boastful as to the limbs we save in these "triumphs of conservative surgery." Very often the limb is so much damaged as to be of but little use, and now and then the patient may request its removal after he has recovered, and when the final result as regards both limb and life is evident. Still in all these life has been saved, and, in most of them, the limb is a source of satisfaction, and of some degree of use.

If, then, you ask me to summarise the principal points in which the impressions I have obtained from experience differ from those with which I began the practice of surgery, I would say briefly—1st. That I have come to think less highly of amputation as a means of saving the patient's

system from irritation and exhaustion. When I have to decide as to a primary amputation I think more of the possibility of local reparation, and much less of what may ensue to the patient's system during that repair. If it is manifest that the limb can never be repaired, cut it off at once, but if there is a bare chance, then leave it on without thinking much of the effect of the suppuration on the patient's strength. A compound fracture is very dangerous, but a primary amputation of a large limb is scarcely less so. 2ndly. As to secondary amputations I would adopt nearly the same rule, that is, to estimate the local conditions, and to almost disregard the constitutional ones. If the limb has become absolutely hopeless, remove it, carefully selecting the proper time, and the later in reason usually the better. If, however, the limb is not hopeless, and the patient's constitutional symptoms are those which have led you to think of relieving him by amputation from "the source of exhaustion and irritation," then resist the temptation. Under such circumstances your patients are in the utmost danger whatever you do, but I think that in the long run they will do a little worse if you amputate than if you decline to. I speak of course only of the general rule. I know that there are exceptions, such, for instance, as when in addition to the original fracture, a large joint has recently become involved, and threatens to add its quota to the general disturbance. 3rdly. As to the time for secondary amputations. Wait till suppuration is fully established, and the inflammatory fever has subsided. When this is the case, when the wound is granulating, and the patient eating well, you may amputate with great safety. It is astonishing what patients will bear in the way of suppuration from large wounds, provided no specific pyæmia has set in. Indeed, if once free suppuration has been established without the occurrence of rigors or other pyæmic symptoms, it is very rare for the patient to sink, however hopeless may be the local condition as regards final repair. A good example of this we recently had in the case of an old woman (upwards of 70), whose left arm had been so extensively injured that the skin of almost the whole extremity was destroyed. She remained for weeks exceedingly low, with dry tongue and quick pulse. The arm was clearly beyond possibility of reparation. At length the wound granulated, and she began to improve and to take food well. Convinced now from her own inspection of her limb that it could never heal, she at length reluctantly consented to amputation. This I did just below the shoulder-joint, and she recovered quickly. Had the operation been done earlier, it is my conviction that she would have died. A few months ago I saw a young gentleman at the Reedham Orphans' Home, who had had his left foot crushed in the cogged wheel of a steam engine. Dr. Rose, with whom I had attended him, had been convinced from the first that the limb could not be saved. The ankle-joint was opened, the astragalus broken, the tarsal epiphysis of the tibia torn off, besides most extensive damage to the soft parts. Four days had elapsed from the date of the accident when I first saw him. He was feverish, and had a quick pulse, and the wound was scarcely beginning to discharge. I advised to wait, and we waited ten days longer. Suppuration was then profuse, and the wound very large, the tendo achillis and a strip of skin were the only structures which remained entire. But in spite of the discharge the boy's state had much improved, and we now amputated with, I believe, very much less risk than would have been incurred at any previous time. He did well. Two more cases, and I have done. One of them is an unsuccessful one, but I shall still in it try to justify the line of practice I pursued. One evening, about a year ago, an elderly man, very drunk, was carried in, who had been knocked down in the street, and had the wheel of a cart over his right shoulder. It did not look to be much damaged, but on examination we found the clavicle broken, and the scapula comminuted, whilst the arm was dragged so far away from the side that the fragments of the clavicle did not touch. The only wound of the skin was a hole large enough to admit two fingers in the middle of the axilla. Having passed my finger into this, I found that it entered a very large cavity, that the great pectoral muscle was torn across, and that the axillary artery suddenly ceased to pulsate about the middle of its course. There was no hæmorrhage going on, and I believe there had been but little. The limb was cool. Having diagnosed laceration of the axillary artery in addition to the other injuries, I believe that my house-surgeon and dressers were all of opinion that primary amputation at the shoulder-joint was the proper measure. I preferred, however, to try to save the limb, inasmuch as no one of the lesions was necessarily destructive to its integrity, and that the whole combined might perhaps prove quite as little serious to the patient's chance of recovery as an amputation which must remove not only the arm, but the entire shoulder as well. The laceration of the artery, although it endangered did not necessitate gangrene of the limb. We had the limb wrapped in cotton-wool, and placed close to the trunk. With extreme rapidity the whole of the damaged member passed into gangrene, and the man died on the third day. You will observe that he was a drunken man, of unsound constitution. Now, although the result of trying to save was unfortunate in this case, I am very doubtful whether amputation would have done any better, or, which is the better way of putting it, whether if two half-dozens of parallel cases were treated, the one set by amputation, and the other without, the balance would not be on the side of the latter.

My last case is one still in the wards. A dissolute woman, pale, stout, and flabby, whilst drunk, fell out of a window, and was afterwards brought here with a severe compound fracture of both bones of the right leg in the lower third. The skin was most extensively torn, the laceration almost meeting in front. The bones were comminuted, and the muscles contused. She was in a very bad state for an operation, having lost much blood, and being collapsed, in addition to intoxication. I decided to venture to try to save it, and taking advantage of the fact that the wound surrounded the back of the limb, I put it up at once in plaster of Paris, leaving the wound exposed. We kept the plaster of Paris on for some six weeks, the limb being swung. Contrary, I believe, to the expectations of all, the woman rallied slowly, and improved in health. The fracture is now united, although the wound is not wholly healed. In this case, it is my impression that primary amputation instead of increasing would have diminished her chance.

Original Communication.

ANATOMICAL NOTES—No. II.

By ALEX. MACALISTER, L.R.C.S., L.K.Q.C.P.,
DEMONSTRATOR OF ANATOMY ROYAL COLLEGE OF SURGEONS, ETC.

VII.—IRREGULARITY OF THE SPERMATIC VEIN.

THIS vessel, it is well-known, usually opens on the left side into the left renal vein, while on the right it joins the vena cavæ inferior directly. In a subject dissected, March, 1868, the right vein exhibited a singular arrangement. Passing upwards to the right side, it divided into two branches, opposite the upper border of the fourth lumbar vertebra. One of these, a larger trunk than the original spermatic, passed directly into the vena cava in the usual position, while the other ran upwards and joined the right renal about half an inch before that vessel opened into the ascending cava; it was singular in this specimen that the two branches derived from the spermatic, were either of them larger than the parent vessel. On laying them open the valvular arrangement was found to be as follows:—The valve of M'Donnell was small but distinct. Another valve existed in the spermatic vein at its point of division, but there was no sign of any fold in either of the branches, or at their openings.

VIII.—VARIETY OF THE PLANTARIS MUSCLE.

In both legs of a male subject, there existed a long curved muscular head for the plantaris, superadded to the ordinary exo-condyloid origin. This accessory belly was twice the size of the normal plantaris, and arose from the upper and anterior part of the outer condyle, and from the tendon of insertion of the vastus externus, about half-an-inch posterior to the side of the patella. It passed at first directly backwards, and then forming an arch whose concavity includes the outer condyle, it descended and joined the ordinary muscle just as it was uniting with its tendon.

An accessory or third head of the gastrocnemius is not a very rare anomaly. When it exists it arises usually from the back of the femur, and is inserted tendinous into the union of the two lateral gastrocnemial heads, I would regard this muscle as of the same type, only differing in its union being with the plantaris instead of the gastrocnemius. They both are representatives of the brachio-fascialis in the upper limb.

The same subject possessed an accessorius ad calcaneum, similar to the muscle of the same name described by Gantzer, arising from the posterior border of the tibia, and from the deep tibial fascia; passing downwards it became tendinous, and was inserted into the musculus accessorius. A muscle somewhat similar is described by Turner ("On the Variability of some Structures in Human Anatomy," Proceedings of the Royal Society of Edinburgh, 1865.)

IX.—ANOMALOUS ORIGIN OF THE DIGASTRIC.

The digastric muscle of one subject on the left side arose by a second head from the styloid process above the stylohyoid, and below the stylopharyngeus. The stylohyoid muscle was present and normal, perforated by the tendon of the digastric as usual. This additional origin has not, I think, been before noticed.

X.—THE NASAL NERVE.

I owe to my industrious pupil, Mr. Kelly, a note of the occurrence of a singular variety of arrangement, namely: the passage of the proper nasal twig of the ophthalmic branch of the fifth nerve, through the posterior ethmoidal foramen.

XI.—SUPERIOR THYROID ARTERY.

As an additional variety of the branches of the superior thyroid artery, I may mention that in one subject recently dissected, the superior laryngeal and hyoidean branches of that vessel arose by a common special trunk from the external carotid on the same level as the origin of the common trunk for the lingual and facial vessels.

XII.—STERNO-MAXILLARY MUSCLE.

The anterior fibres of the sterno cleido-mastoid muscle were attached, in a subject dissected during last month, to the angle of the jaw and the stylo-maxillary ligament, by a distinct round fascicle which lay under the cervical fascia, and crossed over the carotid vessels; this arrangement occurs in some ruminants.

XIII.—ACCESSORY PTERYGOID.

A slip of muscle which not uncommonly exists, was found in the same subject as No. IX., arising from the outer surface of the external pterygoid plate and from the lower border of the temporal crest on the great wing of sphenoid, crossing the external pterygoid muscle, it ran to be inserted along with the internal pterygoid into the angle of the lower jaw.

XIV.

On both sides of a subject recently dissected, there existed a third pectoral slip, arising from the cartilage of the sixth rib, and passing to be inserted into the capsule of the shoulder and the head of humerus, this was supplemented by a second slip, from the latissimus dorsi, which was inserted into the same place. Crossing the external or pectoral slip, and also the great pectoral, was the direct mammary artery, a large branch of the axillary rarely present, which is distributed to the mammary gland. The second slip of the pectoral, described above, is interesting, because it is an arrangement which I have figured and mentioned in some of the quadrumana (Proceedings of the Natural Historical Society of Dublin, 1866).

XV.

One of the most singular varieties in the tendons of the fore-arm muscles occurred in a subject dissected during last month; in it the flexor pollicis longus supplied the index-finger and sent no slip to the thumb, while the long tendon, which should have come from the flexor pollicis, was traceable only as far as the annular ligament, to which it was inseparably connected; the flexor sublimis was normal, and the flexor profundus supplied only three fingers; the only other anomaly in this arm was a double extensor ossis metacarpi pollicis.

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

OPERATION FOR VESICO-VAGINAL FISTULA.

By Mr. CROLY.

Mrs. G., aged 35 years, a strong healthy woman, residing in the country, was attended in her fourth confinement by a midwife. The labour was tedious, and the bladder allowed to become over-distended. Medical aid was *not* sought in time, and perforation was obliged to be resorted to. The patient progressed favourably for a fortnight, and passed water naturally. It was then found that she could not retain the urine, this led to an examination, when it was ascertained that she had a vesico-vaginal fistula. Her medical attendant recommended her to the care of Mr. Croly, who admitted her into the hospital, and having examined the case with his colleague, Dr. Beatty, the fistula was discovered situated near the os uteri, and at the right side, of small size; the communication between the vagina and the bladder was oblique, and so indirect that it was difficult at first to ascertain its precise position. The patient suffered from the usual distressing symptoms, rendering her existence miserable.

Mr. Croly performed the operation in the following manner:—

The patient was placed leaning over a table of convenient height and in a proper light, the duck-bill speculum was introduced, and held well up by an assistant. The lower margin of the fistula having been raised with a double hook was "vivified" by incising it with a long-handled straight knife, and then the upper margin was similarly treated. Five fine iron wire sutures were introduced with the tubular needle at a sufficient distance from the margin and the wires drawn together by the "twister" approximated the edges of the aperture. The ends of the wire having been cut off a piece of lint was placed transversely beneath the projecting sutures to protect the soft parts. A full sized male gum-elastic catheter was then introduced into the bladder, and retained by tapes, which were secured with adhesive plaster to the back of each thigh. The woman was placed in bed in the prone position. The end of the catheter was introduced into an empty soda-water bottle placed between her thighs to receive the urine.

A sedative was administered, and small doses of opium were directed to be taken at short intervals.

The nurse was instructed to syringe the vagina several times daily with cold water and "Condy's fluid." On the fifth day the bladder was injected with water coloured with "Condy's fluid," and as none escaped through the fistula, Mr. Croly concluded that union had taken place, and accordingly he carefully removed the sutures. The result was most satisfactory, and the patient returned to her home in excellent health and spirits—the urine passing only through the urethra.

Mr. Croly observed to the pupils the necessity for making the *lower* incision first to prevent the blood ob-

scuring the view, which should result if the upper margin was first "vivified," and the necessity of inserting the sutures at a safe distance from the edges to ensure their being retained. He also explained his reason for having incised the fistula *tansversely* in the line of the muscular folds of the passage, and dwelt upon the importance of the administration of opium in such cases to prevent spasm of the bladder.

SIR PATRICK DUN'S HOSPITAL, DUBLIN.

EXCISION OF THE KNEE-JOINT.

On the 2nd inst. we had an opportunity of hearing Mr. Butcher deliver his Introductory Clinical Lecture on Operative Surgery, with special reference to the operation for excision of the knee-joint. The theatre was filled with students, and several members of the profession were also present.

After some preliminary remarks on the history of this operation, and its revival in later years, Mr. Butcher introduced to his audience a man named John Game, a shoemaker by trade, on whom he had operated with great success fourteen years before ; and he stated that it was the first instance in which he had performed the operation in question. After a minute account of the personal history of the man, and of his state of health previous to and at the time of his admission to Mercer's Hospital, the lecturer described the operation as follows :—

The patient was placed upon a table, lying on his back, and in a few minutes was brought under the influence of chloroform. The leg at the extreme of tension was steadied, the sole of the foot being planted on the table, and was so held forcibly, while the thigh was rigidly fixed by a second assistant. Standing on the left side of the patient, the operator leant over the knee, steadying its outer side against his chest, and with a strong scalpel he cut along the inner side of the joint to about the extent of five inches; this incision was commenced below, at a point about two inches lower down than the articulating surface of the tibia, and corresponding to a line a little anterior to its inner sharp edge. The knife was at once thrust down to the bone, and, holding the same relationship, was carried upwards along the femur for three inches. The saphena vein was thus gradually left behind the track of the wound. A similar incision was rapidly made on the outside, commencing below the head of the fibula, and was carried upwards above the external condyle. Through the entire extent of this also, the knife was swept along the bones. Both vertical incisions being completed, they were connected by a transverse one, passing an inch above the attachment of the ligamentum patellæ to the tibia. The latter wound opened the joint fully. The lower flap was freed downwards a short way, while that containing the patella was dissected upwards, but with some difficulty, because of the thickly matted cellulo-fibrous tissues which constituted its bulk. The internal and external lateral ligaments were next divided, together with adventitious bands, the result of organized lymph deposits. The anterior crucial ligament was destroyed, but the deeper fibres of the posterior remained intact and incorporated by dense structure, with the posterior ligament of the joint. These in turn were divided, but much difficulty was experienced in detaching them from the posterior surface of the bones, with due consideration for the poplitæal vessels, which not only lay upon the dense elastic material, but were embedded in it. The knife was next rapidly swept round the condyles of the femur, *the disease not extending higher*. In the same way the articulating end of the tibia was freed from the soft parts around its circumference. The ligamentous structures being thus cut through, the leg was forcibly flexed, and the ends of the bones thrust forward. Now the accuracy of the diagnosis was fully verified. The femur presented its external condyle, nearly all removed by caries, while the internal condyle was not at all so extensively diseased. Its posterior half was stripped of its cartilage of incrustation, and was carious behind the intervening space. There was also caries between the condyles. The external condyle of the tibia had its cartilage of incrustation removed ; and it had been replaced by a thick fibrous substitute, while the internal condyle of the tibia presented its normal appearance—a strong evidence of the efforts of nature to check disease. The patella was carious, hollowed, and reduced to a mere shell, therefore it was carefully dissected out, the integuments being preserved, with the fibrous attachments implanted at its upper and lower edges. Having sufficiently exposed the bones, the operator proceeded to cut off their extremities, and for this purpose he used his own saw. Its blade being turned in the supports, and thus steadied, it was pressed with ease behind the condyles of the femur and made to cut forwards. A few movements sufficed to complete the section. In a similar manner its serrated edge was placed behind the tibia, and urged forwards so as to remove a thin osseous slice along with the surface of the bone. The head of the fibula was not diseased ; as it lay below the surface of the tibia it did not prevent the apposition of the bones, and was, therefore, left intact for that reason, as also because the operator did not wish to interfere with the attachment of the biceps.

Mr. Butcher now made the man walk about the theatre, and show, by various movements and evolutions, that he really had an excellent limb, with which he had been able sometimes to walk 20 miles in a-day ; and the quondam patient showed how the stiff knee was admirably fitted for pursuing his business, being, in fact, used for hammering shoes on.

He stated he was the third or fourth person who had excised joints in more recent times. He had five cases, all of which were successful : four were now living, and the fifth died of fever while in hospital after operation, but not until the bones had firmly united, a pathological fact of value, of which he had not been able to ascertain ocular proof in the other four. Here he showed the pieces of bone cut off in the several cases, and the *united* bone which had been removed at a post-mortem examination in the fifth case. The union was complete, and as firm as a rock. He also showed full-size drawings of the surfaces of the various bones, showing the extent to which caries had proceeded at the time of operation.

Mr. Butcher objected to the *semi-lunar* incision, because it does not, in his opinion, leave room to drain off the accumulated fluids, which tend to the poplitæal space, and lead to the formation of abscesses. He also objects to Syme's method of a double semi-lunar incision, one above and one below the patella, because by it the integument is partly taken away. Further, he thought the crucial incision was objectionable, because it gives too little room, and he advocated the H incision, because it saves the poplitæal space nearest the bones, and allows the fluids to escape laterally. He advised the bones to be *evenly* cut, from behind forwards, and forcibly showed the various evil results of not attending to this important point.

Further, he strongly advocated the use of chloroform, and read a report of a case operated on by the late Sir P. Crampton, in which the great suffering of the patient without the use of this anæsthetic was graphically described. If the disease extended higher than the condyles of the femur, he insisted that it was not a case for resection. He summed up thus :—

1. The case should be judiciously selected, and should not be one with too much osseous disease.
2. All the arteries should be properly secured ; and
3. The limb should be put up *at once* with the anterior splint and footboard below. He dwelt minutely on these points, which he enforced by various arguments ; and concluded amidst the applause of his audience.

Cholera is officially stated to have carried off 20,000 persons in the city and province of Buenos Ayres since its return in December last ; other accounts make the number 30,000.

Literature.

THE PHYSIOLOGY OF DIGESTION.

A TREATISE on digestion and its disorders by such an excellent physiologist as Dr. Pavy cannot fail to be both interesting and instructive. It is in the disorders of the digestive process that the teachings of physiology come in powerfully to assist the practical physician in devising methods of treatment both by diet and medicine; and though undoubtedly dyspepsia, like other diseases, has its pathology, and has been treated of recently by a most able writer from a pathological point of view, still for practical purposes of cure, it is very possible that the physiological view may be the most promising. To quote Dr. Pavy,[1] at page 6 we read:—"Pathology has not thrown much light on the subject of dyspepsia. Cases frequently happen where strongly marked symptoms of dyspepsia have been remarked during life without there being, even under microscopic examination, any textural alteration discoverable after death."

The case reported at page 98 certainly is one in point to illustrate the foregoing statement. Referring to one of his own in-patients at Guy's, ill with incessant vomiting, Dr. Pavy writes:—"His case was such as to lead to the opinion that malignant disease of the stomach existed, and a fatal result seemed rapidly approaching through the effects of sheer inanition. After a number of remedies had been prescribed in vain, half a grain of morphia was ordered to be taken in the form of a pill three times a day. The pill was retained, and its effect was almost miraculous.

"The vomiting ceased, and the patient, upon whose case so grave an opinion had been formed, and who seemed at the very verge of death, was restored so as to be able to leave the hospital in about three weeks' time."

The first 86 pages of Dr. Pavy's work treat of the physiology of Gastric digestion, and are full of most valuable information. Of special interest are the author's remarks on the digestion of the stomach itself after death. The experiments detailed are well contrived to prove that the stomach is actually digested by its own juices after death under certain conditions, and that it is not the "living principle," as alleged by Hunter, that prevents the occurrence of this result during the life of the individual, is proved by observing the digestion of the legs of a live frog, or the ear of a rabbit introduced through a gastric fistula into a dog's stomach, while digestion is in progress.

The suggestion of Bernard, that the stomach owes its escape from self-digestion and perforation during life to the protective influence afforded by its internal lining of epithelium, is disproved by the fact that the excision of a patch of mucous membrane from the stomach of a living animal is not followed by the digestion of the subjacent parts.

Digestion goes on in the stomach without the structures opposite the part denuded of epithelium exhibiting any influence of attack. Eventually, the part of the stomach that has been denuded of epithelium heals completely by cicatrization.

The view that Dr. Pavy offers, as most of our readers are, doubtless, aware, in explanation of the immunity enjoyed by the stomach from being digested by its own secretion during life, is founded upon the permeation of the walls of the stomach by an alcaline current of blood. After death the flow of this alcaline current ceases, and then the acid of the gastric juice acts upon and corrodes the stomach.

When in a living animal the current of blood in the walls of the stomach is arrested by ligature of the vessels, then digestion of the stomach wall has been observed to take place.

In the case where the live ear of the rabbit or the legs of the frog are digested, it is believed that the neutralizing power of the alcaline blood is insufficiently strong to overcome the acidity of the gastric juices.

The disorders of gastric digestion, acidity, flatulence, vomiting, &c., are all treated of severally and briefly. With respect to acidity and its cure, the author says at page 137, that by the continual administration of alcalies, "a permanent removal of the morbid state may be oftentimes brought about." For our own part we have more faith in the mineral acids than in the alcalies, as permanent curers of acidity of stomach. The prolonged use of alcalies seems to us to injure the tone of the stomach and to weaken and impoverish the blood. Where, however, the alcaline treatment fails, we are exhorted to try acids, and the nitric acid is, on the authority of Abercrombie, strongly commended.

Before we are introduced to the disorders of intestinal digestion, we have an excellent introductory chapter on the physiology of this process. The minute structural anatomy of the intestinal walls, of the valvulæ conniventes, and the villi, is given with completeness and yet in a condensed form. The observations at page 164, on the functions of the pancreas in the digestion of fat, are worthy of attention, especially now when we hear so much of pancreatic emulsion as a remedial agent in phthisis.

We are told at page 164 that the first action of the alcaline pancreatic juice or fatty matters is of a physical kind, emulsifying the fat, but after a few hours rest this milky emulsion exhibits an acid reaction, arising from the decomposition which the fatty matter undergoes. The neutral fats are acted upon by the pancreatine, and resolved by it into their constituent acids and glycerine. The liberation of the fatty acid thus accounts for the acid reaction which the emulsion after a time acquires.

We find that Dr. Pavy has seen reason to modify the views he formerly held respecting the action of the pancreas on azotized aliment. Corvisart, as is well-known, has long maintained the digestive powers of the pancreatic juice over albumen and fibrin, but Dr. Pavy was of opinion that the solution of the albumen and fibrin arose rather from putrefactive change than from the solvent action of the pancreatic juice.

After carefully going over Corvisart's experiments, Dr. Pavy has observed pancreatic juice to act as a solvent of the azotized tissues, though it does not, like the gastric juice, attack the bones.

The chapters on the treatment of functional disorders of the intestinal digestion are brief and plain; the author holds by the time-honoured Formulæ of the Guy's Pharmacopœia, which he finds sufficient to meet the requirements of those who have come under his hands as patients.

With such elaborate and complete chapters on the physiology of digestion, one is led to expect almost an equal minuteness in the chapters devoted to the physic of indigestion; and yet we would hardly call this a fault in the work, for the author speaks from his own experience, and does not string together a whole host of remedies, tried and untried; a plan which has the effect of puzzling the practical man with a very awkward "*embarras de choix*" in selecting his remedies.

1 On the Function of Digestion; its Disorders and their Treatment. By F. W. Pavy, M.D., F.R.S., Fellow of the Royal College of Physicians, Senior Assistant Physician to, and Lecturer on Physiology at, Guy's Hospital. Pp. 217. London: John Churchill and Sons.

PNEUMONIA.

Dr. William Addison, the author of "Cell Therapeutics," and of "Healthy and Diseased Structure," has issued an interesting brochure,[1] in which he maintains with his well-known ability, that two kinds of inflammation, common and specific, may be present in any given case, and that the complication is not rare in pneumonia.

He thinks that nature takes advantage of the local action of inflammation to eliminate impurities from the blood, as may be seen in external granulation. Minor impurities of blood will prevent the healing of a sore by granulation, as the surface is employed by the blood for eliminating purposes. Thus, healthy is replaced by diseased pus. Healthy granulations may be in close proximity to others degenerating into ulceration, and so in the same sore a specific and common inflammation may co-exist. If so, why not in internal inflammations like pneumonia and bronchitis.

This power of granulations to take on an eliminative action is the true explanation of the use of issues. Pneumonia from local irritation in a healthy patient displays acute symptoms; supervening in the course of fever, it is originated and ministered to by unhealthy blood, and shows only asthenic symptoms. The treatment of these two inflammations, the first common, the second specific, will be as different as is their nature.

Pneumonia may occur from local irritation (heat, cold, dust, gases, &c.) in a patient in robust health, with pure blood and no particular diathesis. It may equally take place in a person whose blood is impoverished or in a state of greater impurity; or in another of gouty, rheumatic, scrofulous, or tubercular diathesis. It may also happen to any one who combines any two or more of these unfavourable conditions. In the first case it will be *common*. In any other it will manifest *specific* qualities.

1 The Co-existence of two Species of Inflammation, with especial reference to the forms of Pneumonia. By William Addison, M.D., F.R.S. London: J. Churchill & Sons. 1868.

It is obvious that these considerations are of the utmost practical importance in respect to treatment. Dr. Addison's pamphlet will be read with much interest. It concludes thus:—

"Both species of inflammation are characterised by *new embryoniform cell growths in the blood-vessel tissue.* The distinction seems to be, that the *cells* of common inflammation are amenable to the ordinary law of growth, susceptible of metamorphosis into the tissue from which they arise; whereas the *cells* of specific inflammation, contaminated by impurity of blood, are deficient in, or have lost these properties; they *are all of them* deciduous, and therefore tend to protract or perpetuate a local sore, or common inflammation. If blood be in an unhealthy state, *specific inflammation* may co-exist with *common inflammation.*"

WEDNESDAY, APRIL 8, 1868.

REVISION OF THE MEDICAL CURRICULUM.

MR. WALTER RIVINGTON, of the London Hospital, has brought before the lately organised Medical Teachers' Association a well-considered plan for the revision of the medical curriculum, to which we invite attention. That we are on the eve of some considerable changes, may well be credited by those who, like ourselves, have had patiently to weigh the various schemes and conflicting opinions that have been recently promulgated. On the other hand, the natural *vis inertiæ* of corporate bodies may be looked upon as likely to prolong the *status quo* for a considerable period. Will this new Teachers' Association be able to stir any of the corporations? If not, there would seem little to hope for.

Sympathizing as fully as any with the grievances of both students and practitioners, we are ever ready to listen to those who think they see a mode of removing some of them, and are, therefore, glad to bespeak for Mr. RIVINGTON a hearing. He comes forward with a resolution to the effect that the curriculum needs revision. In support of this, he urges the many lectures the student is required to attend, and, by an elaborate calculation, attempts to show the impossibility of all the requirements being fulfilled. He takes the first 18 months, deducts the vacations, leaving only 15 months, and finds the student's work, as laid down by the regulations for that time, to amount to 468 days, of 8 hours' work in each. Yet, deducting Sundays, and 12 days for Christmas recess, there are only 379 days in this time, so that the work of 89 non-existing days must be crammed into the already full occupation of the others. No one will be disposed to deny that this is too much for the average student, although there are many who pass through the curriculum with ease, and add to it other favourite pursuits. Of course they neglect something, or if diligent, may feel their knowledge of some subjects sufficient to excuse their attention to it. This brings us to the remedy.

Mr. RIVINGTON would remove botany and elementary chemistry from the course, and make them preliminary studies. These and comparative anatomy he would like to see taught—not at the several schools, but at some central institution like the College of Surgeons—though we should think the Apothecaries' Company more likely to possess all the appliances for botanical and chemical instruction. Then, he would not have *compulsory* attendance on more than one course of any subject.

Here, we apprehend, is the pith of the whole matter. Compulsion has been so long in vogue that it is no easy task to persuade men to credit the possibility of students delighting in their work.

The beaten track must be followed, or character may be lost. True diligence does not consist in bodily presence in the lecture-room, and we hold that more freedom could do no harm. Let instruction be practicable and students will avail themselves of such as they stand in need of, and ought not to be compelled to run in the ruts made by their predecessors. We know a case in point which will show the impropriety of too rigid adherence to rule.

A young man fortunate in his choice of a master was apprenticed as required by the Apothecaries' Society. The practice was elegant, the leisure abundant, the master kind, the pupil diligent and anxious to get on. He had a small laboratory at his disposal, which the master always kept supplied for his pupil's benefit. He had also a very good museum of materia medica and botanical specimens, as well as an unusual assortment of electrical, optical, and philosophical apparatus. Most of the winter evenings were passed by master and apprentice in practical experimentation. What was the result? On passing to the hospital the pupil, who had matriculated during his apprenticeship, found he could gain little instruction from the lectures on botany, materia medica, and inorganic chemistry. These he accordingly systematically shirked—and with this consequence. He was a marked man. He was believed by some of the professors to be idle; and by dint only of great perseverance did he obtain their signatures to his schedules. They did at length sign on the representations of the physicians and surgeons as to diligence in the wards, and within a few weeks our student was a full-fledged general practitioner, college and hall having tested and approved him. A short time after he graduated and proceeded, to the astonishment of some of his fellow-students, to take other honours. They thought him negligent, but he worked hard all the time, and though he omitted lectures on subjects with which he was previously thoroughly acquainted by practical instruction of the best kind, he bestowed on other branches the labour he must otherwise have devoted to them.

What is the moral of all this? should it not teach us the folly of attempting to regulate to a nicety the curriculum which *every* student must follow. Would it not have been a farce to have refused this man the right to be examined, because he had not wasted precious hours in listening to lectures he did not need? We may strive to impart uniformity, but we shall fail, and therefore we raise our voice in favour of a moderate degree of liberty for the student. Let each learn, at least, the theoretical subjects as he will. The examination should be the sufficient test of them.

Yet we are scarcely prepared to endorse all Mr. RIVING-

TON'S conclusions. We should be glad enough for comparative anatomy, for instance, to be taught at the College of Surgeons, and botany, pharmacy, &c., at Apothecaries' Hall. But then the going to and fro would be a source of distraction and loss of time. We know no reason why every school should not teach every branch. It is a question of the mode of tuition. A large class is wanted for a lecture, but a teacher may impart instruction without set lectures. We have taught chemistry and physiology to a single pupil with a success that enabled him to shine, and have had other experience in tuition which makes us think that a large class is not necessary for the subjects proposed. By all means let us have large classes at central institutions, and eventually these may quite supersede the many classes which, in the language of the day, cause so much waste of teaching power. Yet we think each college should be perfect in itself, and offer to those, who wish it, complete tuition in all departments.

A step in the direction desired by Mr. RIVINGTON would be gained by letting students enter for classes and practice at several hospitals. They would find a popular lecturer of any subject at one or other, and the rivalry might act favourably on teachers. There is much to be said, too, in favour of their seeing the practice of different hospitals. The chief point against it is the distraction and loss of time that would occur, and habits of restlessness that might be engendered in the less staid pupils. So many other points press upon us, that we must defer them.

In the meantime, we plead for more liberty and less regulation for students.

MATERIALISM IN THE PARIS FACULTY.

WHATEVER may be the private convictions or opinions of medical men or teachers in this country, we are glad to say that they do not lead to anything like the scandal that has lately occupied the Paris press. We have our so-called godless colleges, our strictly sectarian institutions of all kinds, and yet, practically, we have harmony as well as liberty. Then we have our numerous hospitals, large and small; some slightly endowed, but the majority entirely supported by voluntary contributions. In the wards of these noble charities the services of our profession are freely rendered without fee or reward. In very few is a candidate's orthodoxy allowed to be a test for his fitness for election on the staff, and, consequently, men of every shade of doctrine may be met with amongst our hospital physicians and surgeons. High Church, Low Church, Broad Church, no Church, Romanist, Protestant, Dissenters of every kind, Jews, foreigners of various nations and creeds, are free to join in hospital work. Yet we never hear of attempts at proselytism. The physician or surgeon interfering with the religion of his patients is unknown among us, and rightly so too. For if once our office were to be suspected of this, it would at once be degraded from the lofty platform of true catholicity it has so long occupied. "They manage these things *differently* in France." It appears that numerously signed petitions have been presented to the Senate complaining of the "mode of teaching followed by certain of the Faculties." In the report upon these petitions it is stated that one of the Professors of the Faculty of Medicine taught that "nerve substance had thought as a property, that on life ceasing man found no second, better life, that matter was the God of Science, and that if man possess a soul so does the ape." Another Professor is accused of making Malthus a text for teaching immorality; another of openly advocating materialism; and a physician is said to have ridiculed a poor woman in the hospital for wearing the figure of the Virgin. The petitioners urge that atheists ought not to have a monopoly of teaching in any department, but that students should have the opportunity of selecting other masters. The Senate is to discuss the subject after Easter. The interval will probably develop public opinion on the subject, and we are much mistaken if France does not pronounce some such view as that we have already hinted as our own.

It will not be forgotten that these professors and physicians are both paid by the State, so that the interference of tax-payers may not seem so strange as it otherwise would. We believe, however, that the subscribers to our hospitals would soon find means of expressing their views were any such conduct possible amongst our physicians who are unpaid, as that alleged against some of the Paris Faculty. In commenting upon the matter, *La Presse* says :—

"When a physician paid by the State to attend to the sick in hospital, instead of doing so with the care which their physical and moral sufferings require, sneers at and outrages their religious belief, he seriously fails in his duty; and if the administrators of the hospital do not remind him of it, the interposition of the Senate is properly called for. Whether the patient be Catholic, Protestant, or Jew, his religious opinions should be sacred to the physician who attends him; and the physician acts most improperly in adding to the physical sufferings of the patient the moral torture of the profanation of his faith."

This opinion will find an echo far and wide. The writer does not deny the right of the physician to his own opinion; he sets up no standard of orthodoxy as a qualification for office; he does not even indulge in any inuendoes against those who have suffered theology and metaphysics to blind them to the one subject to which the physician's life should be devoted—sickness, and how to alleviate or remove it. There is no wish, as has been rather unfairly represented in some quarters, to subject the materialists to any pains or penalties, to dismiss Professors who doubt the divinity of Christ, or to give to Catholics liberty of speech and deny the right of reply to others. None of these things are proposed, and assuredly none of them would we support. We have no fear of discussion. In its proper place the more the better. Truth cannot be worthily held by forbidding those who do not embrace it to express their doubts. That religion can be worth little which need fear the opposition of reason. But admitting all this, we cannot join in the taunts of the *Opinion Nationale*, which condemns the petitioners in no measured terms, and seems to think the conduct alleged justifiable.

Liberty full and equal by all means. Discussion public and open none need fear; but we cannot conceal from ourselves that to call the jeers attributed to the physician in question debate is a misnomer. It is absurd to talk of a poor woman ill in bed in hospital, entering into argument with her doctor, and we can only express our surprise that the latter should have given ground for this accusation. We trust his conduct has been grossly exaggerated; for to step out of his way to convict a poor patient like this of superstition, is to add to suffering instead of to relieve it. It is consequently a scandal which the Profession everywhere must lament, for it tends to diminish confidence in the true charity that has ever characterised our services. We hope, therefore, to hear that the charge of having committed such an outrage may even yet be disproved.

We have confined our observations strictly to the question as it affects the Profession morally and socially. Whether the State should exercise control in such cases, or remain indifferent, does not affect the points we have named, while this aspect of the question would lead us into a region of politics which is not appropriate to a medical journal.

THE ROYAL VISIT TO THE COLLEGE OF SURGEONS IN IRELAND.

THE approaching visit of their Royal Highnesses the Prince and Princess of Wales to Dublin, with all the political significance which state pageantry can confer upon it, will be a "red letter" epoch in the memory of the people of Ireland, and for all reasons a most appropriate opportunity for bringing home to the recollection of the Irish the well-nigh forgotten state and dignity of the Royal presence. Whether as an assertion of the supremacy of the crown, following close upon the successful vindication of the majesty of the law against its assailants, or as an exchange of hospitality and greeting between the heir-apparent and Her Majesty's Irish subjects, the occasion is well chosen, and the advent of the Prince well-timed. It is fitting that in the interchange of loyalty and good feeling, the medical profession of Ireland should not be oblivious of its duty, nor the Prince unmindful of the uniform loyalty of its members, and it is with pleasure, therefore, that we make public the following letter in response to the invitation of the Council of the Royal College of Surgeons in Ireland :—

MARLBOROGH HOUSE, PALL-MALL, S.W.,
24th March, 1868.

SIR,—I beg to acknowledge the receipt of your letter of the 21st inst., and having laid it before the Prince of Wales, I am directed by His Royal Highness to assure you that it will afford him great satisfaction to be enabled to visit the Royal College of Surgeons, during the period of his stay at Dublin.—I have the honour to be, Sir, your most obedient servant,

W. T. KNOLLYS.

Robert Adams, Esq.,
President of the Royal College of Surgeons.

The advisers of His Royal Highness will hardly need the suggestion which we venture to offer, that the presence of the Prince of Wales in Ireland, and within the Hall of the Royal College of Surgeons, may fittingly be signalized by an act of special grace and honour to the surgical profession in Ireland.

Mr. Adams, the surgeon-in-ordinary to Her Majesty the Queen in Ireland, elect Regius Professor of Surgery in the University of Dublin, and President of the Royal College of Surgeons, is already, in the opinion and by the common voice of the profession, declared worthy of the highest distinction which might be conferred by Her Majesty, and no course more gracious, more dignified, or more completely in accord with the feeling of the profession could be adopted by His Royal Highness than the placing in the hands of the learned President of the College of a patent of baronetcy. Mr. Adams is exclusively identified with no party, and thus on his elevation to the dignity which he so well deserves could incur the envy of no class. Admittedly the father of Surgery in Ireland, he is at once a writer of the highest repute and a medical politician of the most unsullied character, and in this, his third occupancy of the presidential chair, he has commanded and received the entire confidence of the college over which he has reigned.

These are qualifications in themselves worthy of the same recognition from the throne which has been dealt out with no niggardly hand to the profession in England and Scotland. Beside Sir William Lawrence, Sir Thomas Watson, Sir William Fergusson, Sir James Simpson and Sir William Jemmer, there is no man in Ireland so well entitled to stand as Mr. Adams, and we earnestly believe that, if the advisers of Her Majesty will consent to accept the suggestion we have ventured to offer, they will act upon the verdict of the entire profession which we have endeavoured truthfully to express.

Notes on Current Topics.

The Public Health.

THE mortality returns continue to be favourable. The annual rate for the large towns in the last return was 25 per 1000. It was in the different parts of the kingdom as follows:—22 per 1000 in London, 31 in Edinburgh, and 29 in Dublin; 32 in Bristol, 23 in Birmingham, 27 in Liverpool, 27 in Manchester, 27 in Salford, 25 in Sheffield, 23 in Leeds, 24 in Hull, 27 in Newcastle-upon-Tyne, and 29 in Glasgow.

There were 1320 deaths registered during the week in London, being 316 less than the average number, which is 1636 for that week.

The deaths from zymotic diseases were 252, the corrected average number being 341. Twenty-two deaths from small-pox, 39 from measles, 23 from scarlatina, 7 from diphtheria, 52 from whooping-cough, 33 from fever, and 14 from diarrhœa were registered.

One hundred and seventy-two deaths occurred from phthisis, 153 from bronchitis, 70 from pneumonia, and 69 from diseases of the heart.

We have now had a long series of favourable returns, and we trust that they may continue.

Poor-law Reform.

LORD DEVON'S Bill, now referred to a Committee of the House of Lords, is not likely to excite enthusiasm in any one. It contents itself with patching and tinkering the system which has been proved to be insufficient, and makes no attempt at anything that is entitled to the name reform. It offers, indeed, a few regulations on minor points, which may remedy some of the abuses, but it does not deal with the subject in a broad or a statesmanlike manner. It is therefore weak, if not worthless.

The measure of the proposals may be judged by one of the provisions. Facilities are to be given for religious advice or instruction to the paupers of all persuasions. This is well as far as it goes ; but who has said that spiritual destitution is the grievance of the poor ?

They have been proved to want medical comforts. Medical inspectors would be a simple and certain remedy for many of their distresses. The want is more doctors ; the government offer more parsons. Adequate medical inspection is the one necessity ; clerical supervision is the government prescription. The cry is for food and physic ; the answer is the offer of religious teaching. The pauper asks for bread ; the country is advised to give a stone. The child prays for a fish ; the paternal authorities are about to present a serpent.

Prison Pains and Penalties.

A PRISON in a civilised and christian community is a sad necessity, and proves oftentimes a fearful infliction on the one who least deserves it. Two months' imprisonment with hard labour, not a very heavy sentence, may, it seems, end in the death of a man. It ought not to be so; nevertheless it has been of late in more instances than one. Several strange disclosures were made at an inquest held by Mr. Humphreys last week, on the body of Edward Barrett, 18 years of age, who died, it was stated, from ill usage in prison. According to the evidence he was comparatively well last Christmas, but when he came out of prison after two months' confinement, he was "very ill indeed" and "so weak that he had to lean on his sister's arm very heavily," to get along. He said he was half-starved, and unable to do the work on the wheel. He came down and complained to the doctor, but was put on bread and water for not doing the work, and had been five days out of seven on that diet. Though every kind of nourishment was given him since he came out, he could not work, and was found dead on the Thursday preceding the inquest. Mr. G. B. Phillips, the police-surgeon, said the post-mortem examination showed that death resulted from an infusion of blood into the lungs—that there were tubercles in the lungs—that the body was anæmic and emaciated; that the deceased had probably been consumptive for two years; that it must have been apparent for months past, and that he was unfit to work on the tread-mill. Three or four other men who had been imprisoned gave similar testimony as to the diet and treatment in prison. One of the witnesses said the men were on the wheel from half-past six in the morning till five at night; a quarter of an hour on and a quarter off. At eight o'clock they get one pint of gruel and six ounces of bread; the same for dinner on Mondays, Thursdays and Fridays. On Tuesdays and Saturdays the dinner is eight ounces of potatoes, four of meat, and six of bread. On Sunday the dinner is one pint of soup and six ounces of bread. For supper, at five o'clock, they get half a-pint of gruel and six ounces of bread. The same witness says, when I complained of illness, and saw the doctor, he ordered me the bread and water. At least, he does it in this way—he says "Go on; there is nothing the matter with you," and the warder puts that in a book, and you go up before the governor, who says, "Coming off the wheel without cause. Two days' bread and water." "He only examines you by looking at you." It was proved that at least one other had died, and four or five were rendered so ill that they were obliged to apply to different hospitals for relief.

Such a state of things certainly reflects great discredit on our prison authorities. What kind of care for the proper management of things has here been disclosed? If a man is guilty of death let his life be taken in the most summary and least painful manner—so humanity dictates. But justice dictates as well, that if his crime is of inferior quality, which a few weeks' deprivation of his liberty is sufficient to atone, he ought not to be exposed during those weeks to torture and deprivation which will inevitably entail a miserable death. The jury returned a verdict in accordance to the facts, and it is to be hoped that the communication of the coroner to the authorities will have due effect.

Tasmania and its Climate.

THE visit of His Royal Highness the Duke of Edinburgh to the Australian Colonies has directed general attention to that portion of Her Majesty's dominions. One of the most beautiful and remarkable as regards scenery and climate, according to the accounts which have been given of it, is Tasmania. Some time ago it attracted the attention of Colonel Crawford, late Assistant-Adjutant General of Her Majesty's Bombay Army, who thought it every way adapted as a residence for retiring Indian officers. He is himself now residing there, and through his efforts an act has been passed by which fifty thousand acres of land on the north coast have been reserved for this object. A large number of Indian officers will, it is expected, avail themselves of the advantages thus offered; and will, no doubt, reap the benefit of their choice in the possession of land, with a far lower rate of living than they could find in England, as well as a lovely and healthful climate. Tasmania is situated between 40 and 43 degrees south latitude, and its western shore is washed by the Indian ocean. It abounds in mountains and woodlands, in well-watered dales and fine open downs. It has been thought to equal some of the loveliest parts of Europe, and has been called the "Queen of the South." Its temperature is remarkably equable. From twenty-five years meteorological observations in Hobart Town, it is found that the mean annual temperature in that city is 54 deg., 41 min. The yearly range being from 46·85 in winter, to 61·95 in summer, so that the variation is only 15·10 deg. between the coldest and the hottest parts of the year. These figures show a climate with no extremes of heat and cold—with a "winter mean temperature of Pau" in the south of France, and "a summer temperature of Bushy Heath, near London." It is free from marsh miasma, while neither intermittent nor remittent fevers occur there. No more favourable spot, we imagine, could be selected by those who seek retirement after having spent years of exposure under a tropical sun; nor can those who think of emigrating from the United Kingdom make choice, according to all accounts, of a better distinction.

St. Andrews Medical Graduates' Association.

THE General Session of the Association will be held at the rooms of the Medical Society of London this evening (April 8th), at eight P.M.

With so many subjects demanding the immediate consideration of the Association at this particular time, and having reference to the present political situation, the Council has thought it proper to defer the special debate on the Medico-legal Bearings of Insanity, which we lately announced, to a subsequent session.

We hear that the number of new members to be balloted for is ninety-three, and that probably the first volume of the transactions will be ready for distribution at the meeting.

We should also announce that after the usual business, and the report on Parliamentary matters, there will be a communication from Mr. Glaisher, F.R.S., on a scheme for mutual co-operation in medical meteorology. The President is then to propose a plan for the systematic registration of disease in the United Kingdom.

Indiscriminate Living.

FROM the report of Dr. French, the Medical Officer of Health, which has just been issued, we select the following

particulars, showing the sad state of things resulting from over-crowding among the poorer classes :—In 62 instances adult sons and daughters slept in the same room with their parents, and in three instances in the same bed. In 152 instances adult daughters slept in the same room, and in 56 instances in the same bed, with their parents. In 99 cases adult sons slept in the same room, and in 37 cases in the same bed, with their parents. In 214 instances adult sons slept in the same room, and in 158 instances in the same bed, with their mothers. In 37 instances adult daughters slept in the same room, and in 27 instances in the same bed, with their fathers. In 59 cases the mother, with her adult sons and daughters, slept in the same room, and in 21 instances in the same bed together. In 12 instances the father, with his adult sons and daughters, slept in the same room, and in 6 instances in the same bed. In 7 instances a mother, adult son, and a female lodger slept in the same room, and in two instances in the same bed. In 64 cases a man, his wife, and a female lodger slept in the same room, and in three instances in the same bed. In 12 cases a man, wife, and male lodger slept in the same room. In 39 cases adult brothers and sisters slept in the same room, and in 20 cases in the same bed. Such unnatural association must have a most debasing influence upon the moral and social feelings of those who are compelled to submit to it. Great difficulty may be found in applying a remedy ; but surely some attempt should be made, more than hitherto has been, to provide suitable dwellings for the working classes in our cities and large towns. This is important, not only in a social and moral, but equally in a sanatory point of view. The deaths registered in Liverpool during the year were 14,513 ; the death-rate of the town was 29·4 per 1000 of population, being 3 per 1000 less than the average rate of the previous ten years. The deaths from typhus in each of the six years 1862-67 were 730, 1304, 1774, 2338, 1523, and 656 respectively. The proportion of epidemic and contagious diseases to the total deaths in 1867 was less than that of any year since 1861, being 24·8 per cent.; in 1866 it was 38·2 per cent.

Prison Diet.

A Bluebook has lately been published containing the report of the Committee appointed by the Lord Lieutenant, to investigate the dietaries of county and borough gaols in Ireland. The inquiry was an extended one, and comprised various particulars, such as the present dietary in prisons, that of labourers, artisans, and small farmers in the country ; and a comparison of these with the dietary used in workhouses. The result was that the Committee came to an unanimous decision with regard to the different classes of prisoners and pauper debtors. "The introduction of potatoes into the dietary is strongly recommended, as well as of vegetable soup made (as at the Westmeath Gaol) of oatmeal, onions, carrots, and turnips. In most of the prisons visited the quality of bread, meal, and milk appears to have been excellent. In many places the duty of inspecting and reporting on the food devolves upon the chaplains, and the Committee recommend, as a modification, that a daily inspection of the food should be made by the governor or surgeon, or both ; that the importance of providing good milk cannot be too strongly insisted on ; and that all prisons should be provided with a cream tube and a lactometer. It is also recommended that the bread should be made with whole wheaten meal, or with equal parts of whole meal and seconds flour ; that the meal for breakfast "stirabouts" should be oatmeal, or oatmeal and Indian meal in equal proportions, and that the use of simple gruel should be discontinued, because its nutritive value is of the lowest character."

The Volunteer Medical Service.

A meeting of medical officers of Volunteers was held at the Grosvenor Hotel on Tuesday, 31st March—Mr. Spencer Smith in the chair. Between thirty and forty members were present, and letters had been received from all parts of the country expressing sympathy with the movement. The object was to form an association to obtain for the service a recognition of the position to which it is entitled. Volunteer medical officers desire to render their organization effective, and are not content to be subordinated to their brethren of the regular army. Resolutions were adopted embodying these views, and a subcommittee was formed to carry them out, care being taken that everything was done in regular form through the constituted authorities. Considering that the War Office has invariably to fall back upon the civil branch of the profession in time of need, it would appear probable that it will welcome this desire on the part of Volunteer surgeons to complete their organization. The large reviews, and Wimbledon, afford valuable opportunities of testing its efficiency.

The Irish Branch of the Medico-Political Association.

Dr. Robert McDonnell, F.R.S., has accepted the office of Chairman of the Irish Branch of the Medico-Political Association.

Dr. McDonnell's enlarged and liberal views on matters of medical politics, as well as high scientific reputation, point him out as eminently fitted to become the leader of a movement, the object of which is to give potential expression to the wishes and wants of the members of the profession at large by means of their special representation on the Medical Council, and we congratulate the Association on the acquisition of so influential a name for the chairmanship of its Irish branch. We should consider the profession in Ireland fortunate if it could send Dr. McDonnell to the council as the exponent of its sentiments.

Drs. Charles D. Purdon and William Mac Cormac, of Belfast ; Dr. Michael Brodie, President of the Limerick Medical Protection Society, and Dr. Denis J. Hynes, Vice-President of the Irish Medical Association, have also accepted office as Vice-Chairmen of the Association. Their names will add much weight to this important movement.

Purpuric Fever at Shorncliffe Camp.

The 12th Depôt Battalion has lost two men and has two more ill from cerebro-spinal meningitis, attended with the pathognomic purple petechiæ. The cause of the outbreak is traced to the unsatisfactory sanitary condition of the huts, in one of which three of the cases occurred, and orders have been issued for the immediate inspection of the neighbouring huts, and the remedy of the objectionable hygienic conditions.

Technical Education.

We have great pleasure in recording a munificence that may well be compared with that of Mr. Peabody. Mr. Whitworth has offered to found 30 scholarships of the

annual value of £100 each, to be applied to the further instruction of young men, natives of England, Ireland or Scotland, selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and its cognate sciences, with a view to the promotion of engineering and mechanical industry. The offer was made to the Prime Minister, and has been accepted with an expression of hearty thanks by the committee of council on education. Supplemented as it is hoped this gift may by others, from such as may be inclined to follow the splendid example, this fund may be a source of great benefit to the country, and we join in the wishes so generally expressed that Mr. Whitworth may live to see the beginning of valuable results accruing to the country from his large and generous patriotism.

A Naval Netley.

THE Greenwich Hospital Commission which will shortly be in the hands of Parliament contains, we understand, a strong recommendation that a school for the special instruction and training of naval assistant-surgeons, shall be established at Greenwich on the same plan as the Netley Hospital School. We find a difficulty in recognizing any special department of professional information which would justify the large expenditure which this suggestion would entail. The subjects which are not common to both military and naval medicine are very few and could, we believe, be efficiently provided for by an extra professor at Netley.

A Competitor for Chloroform.

THE use of nitrous oxide gas, which has been for some time on its trial in America, has been, last week, introduced into London practice at the Dental Hospital by Dr. Evans of Paris, who, in a series of practical demonstrations,has made a very decided impression on the minds of those gentlemen who had an opportunity of observing the results. On consecutive days the induction of anæsthesia by the inhalation of the gas was tried, and so far, with complete success. The peculiar characteristics of the anæsthesia are the remarkable rapidity with which it ensues and disappears. The patient holds the mouthpiece of the inhaler between his lips, and his nostrils are closed. After a few inspirations the heart's action becomes increased in force and frequency ; in twenty or thirty seconds the insensibility is complete, and within about half a minute more the patient is so far restored as to be able to walk. The whole period from the first inhalation until restoration, varied from three-quarters to two minutes, and in no case was pain experienced. Pallor and lividity of the face, which are such serious indications in chloroform administration, are common under the use of nitrous oxide, and in some cases apparent respiration and pulsation ceased, but without any ill result. The observed effect of the gas would appear to prove that its use is suitable only to rapid operations, and that prolonged anæsthesia could not safely be effected by it.

Death of Professor Pirogoff.

A MOST untoward and extraordinary fatality has deprived the profession of one of its brightest ornaments, in the death of Professor Pirogoff, whose name has been immortalised in the amputation at the ankle-joint known by his name. In the discharge of his professional duties while returning from attendance on a patient near Odessa, he was attacked by a gang of footpads. By a most gallant contest, in which he slew two of his antagonists, he escaped the violence and robbery which was intended, and ran to his house, but the excitement was too much for him, and culminated in an attack of cerebral congestion, of which he shortly died. The deep regret with which this melancholy intelligence has been received is increased by the circumstances under which European surgery has lost one of her most talented representatives.

The Rationale of Rowing.

THE victory of the Oxford crew in their eighth contest for oarsman's blue ribbon, was so much a matter of course that no one has thought of inquiring the reason why for eight years the entire strength of the athletes of Cambridge has failed in the competition. That it was not altogether a failure of skill, is shown by the evident hesitation of connoiseurs to declare on the preliminary trials of the crews, the superiority of one or other, while the odds against Cambridge were not at all higher than the previous repeated victories of Oxford would justify. There can be no reason why the Cambridge boat should be heavier, or its picked crew of inferior metal to their antagonists. By these considerations we are driven to the conclusion that there must be a fundamental defect in the training of the Cambridge men, and that if we were in possession of the details of each system, we would find a good reason for the superiority of Oxford. May not the Cambridge crew be either under or over-trained—their "spurts" too short or their rate too slow. We can easily comprehend that rowing exercise should be supplementalized by vigorous walking, and that the fault may be in the cultivation of the muscular development of the back and upper extremity, and the neglect of the thigh and leg muscles, which play an important part in the use of the oar.

The Professorship of Hygiene in the Royal College of Surgeons of Ireland.

THE election of a Professor to the chair vacated by Dr. Mapother will take place in accordance with the bye-laws on to-morrow (Thursday), and for that purpose the Council has been summoned to attend. Four candidates have submitted their qualifications to the consideration of the Council—Dr. C. F. Moore, one of the Physicians to the Cork-street Fever Hospital, lately appointed an Inspector under the Merchant Shipping Act ; Dr. Little, Physician to the Adelaide Hospital ; Dr. D. B. Hewitt, Physician to the City of Dublin Hospital, and Demonstrator of Anatomy in the School of the College ; and Dr. Cameron, Lecturer on Chemistry in the Ledwich and Steevens' Schools, and Analyst to the City of Dublin.

The Professorship of Hygiene is a purely honorary position, no emolument attaching to it except the fees for certificates, which, as attendance on the lectures is not required by any examining board, are seldom required. The course has been always, under the able teaching of Dr. Mapother, a popular one, and largely attended by extra-professional persons. In anticipation of the election, the Council, feeling that the Professor should not be called upon to provide the essential accessories for lectures from which he receives no pecuniary return, have on the motion of Dr. Mapother, voted a sum of £20 for this year, for the purchase of diagrams and apparatus which shall be the property of the college, and available for the use of

future professors, and have by the same resolution decided that the course shall consist of twelve lectures, which shall be delivered in the College between the months of May and June.

Although no direct remuneration is derived from the professoriate, it is a position which affords a valuable opportunity for the cultivation of a science to which of late years much public attention has been directed, and the position of Professor of Hygiene in the Royal College of Surgeons could not fail to recommend its occupant to favourable consideration, whenever special qualification in this direction was a requirement.

We learn that the Board of Trinity College, Dublin, have arrived at the determination of creating a Regius Professorship of Surgery on a similar footing as the Regius Professorship of Medicine now held by Dr. Stokes. The existence of a University Professor of Surgery hitherto has been somewhat of an anomaly, as by Act of Parliament Dr. McDowell is University Professor of "Anatomy and Chirurgery." For this change the permission of Her Majesty the Queen will be required, and it is proposed to petition Her Majesty to appoint Mr. Adams, the President of the Royal College of Surgeons as the first Regius Professor.

Proceedings of Societies.

SURGICAL SOCIETY OF IRELAND.

March 13, 1868.

Mr. Porter, Vice-President of the College, in the Chair.

Members of the Society present:—Messrs. Fleming, Jameson, Cronyn, Eustace, M. Eustace, H. Kennedy, W. Moore, R. H. Moore, C. Moore, Kirkpatrick, White, Martin, Collis, Purcell, Elliott, H. G. Crotty, Baker, Wilson, Stronge, Roe, Coulter, Willis, Geoghegan, O'Leary, Grimshaw, Guiness, Clerke, Nugent, Mapother, Wharton, Morgan, Hewitt, Purser, R. M'Donnell, Jacob, Owens, F. Kirkpatrick. Telford, Morrogh. Ferguson, Crotty, E. Hamilton, Swan, Usher, O'Grady, J. Benson, Sibthorpe, Brady, F. T. Porter, Barker, Minchin, Tyrrell, Benson, Honorary Secretary.

PEMPHIGUS GANGRENOSUS.

Dr. J. Morgan exhibited a specimen of this disease, taken from the body of a girl of eighteen, who was admitted to Mercer's Hospital on the 26th of last month. She had been well up to three weeks previously, and the characteristic bullæ began to appear on various parts of the body. There were two on one buttock, and one on the other; there was one on the abdomen, and one on the thigh, of which he took the cast now on the table. There was a slough on the lower lip; a slough on the outside, and one inside, eating down into the gum. The girl came into hospital on the 26th with these well marked characteristic sloughs. She died on the next day, and he removed the preparation, and put it up in the solution in the bottle on the table. One of his reasons for showing it, was to point out the efficiency of the solution. Previously to the girl's death he used the solution, and he thought, with much benefit. It certainly corrected the fœter to a considerable extent. This solution was made with sulphite of lime.

RECTO-BULBAR ABSCESS AND HYPOSPADIAS.

Dr. Mapother presented pathological specimens, removed from the body of a man, aged 65, who died last Sunday in St. Vincent's Hospital. He was admitted, fourteen days before, for a sloughing abscess in the recto-bulbar space, the skin covering it having already given way. Around this opening there was great hardening, especially towards the rectum, reminding one of the "phyma" of Pott; but there was no gangrenous emphysema. The opening, as you will perceive, was about 1½ inches by ¾, and led back to a cavity about 2 inches deep in the left ischio-rectal fossa, the areolo-adipose tissue of which had sloughed out. There was no evidence of urethral perforation, for no urine escaped, as he passed it along that canal without difficulty in a natural stream. He said he had had stricture, but that the dilatation treatment employed many years ago had relieved him, and a No. 6 catheter passed readily into the bladder. The abscess appeared to me to be behind the turning of Colles' middle perineal fascia, to join the triangular ligament, and as the urethra never gives way behind this situation, I did not look on the abscess as the result of urinary infiltration. The urine was albuminous, the skin anæmic, and the legs œdematous, from which we concluded that he suffered from Bright's disease. That malady, together with the sloughing abscess, proved fatal, death being preceded by typhoid delirium, and finally coma. The absence of infiltration or of tension, the patency of the urethra, the cessation of sloughing, and the largeness of the opening indicated that incisions were uncalled for, and the treatment consisted in warm dressing locally, and bark and ammonia, wine and nourishment internally. The kidneys were found in a state of complete fatty degeneration, the bladder slightly fasciculated, and the urethra somewhat narrowed at the junction of the membranous and bulbous portions. There is here a small depression bounded by frœnicula, but no opening whatever. This part of the canal, as well as the prostatic sinuses are reddened. The sloughing abscess having been completely limited by the division of the pelvic fascia into its anal and obturator layers, produced no peritoneal or retro-peritoneal inflammation. The penis presents a good specimen of hypospadias; a *cul de sac*, about three lines deep, occupies the position, and follows the shape of the meatus, and the urethra opens about three-quarters of an inch behind this by a transverse valve-like slit.

HÆMATEMESIS FROM EMPHYSEMA.

Dr. Hewitt said—The man from whom the preparations before them were taken, was admitted into the City of Dublin Hospital on the 1st or 2nd of February, labouring under symptoms of chronic bronchitis with emphysema, and accompanied by anasarca of the lower extremities, which was due to cardiac obstruction, the urine being free from albumen or tube casts, and the kidneys were subsequently found to be quite free from disease. The chest everywhere exhibited extreme clearness upon percussion, and there were all the usual symptoms of chronic bronchitis with emphysema. There was extreme cyanosis and great viscidity of the expectoration, which was muco-purulent and sometimes nummular. He first treated him on Dr. Stokes' plan, of giving stimulants along with tartar emetic. Under this treatment, his natural colour almost entirely returned, and he became so much better that he left hospital in order to have a short spree. His son came for him, saying that some friends had come up from the country, and they wanted him to spend an evening with them. In a week he came back to hospital. He then exhibited more intense dropsy than ever. It now appeared in the upper extremities, in the face, and also in the peritoneal cavity. In turning him from side to side the fluid gravitated to the dependent portion. On examining the abdomen it was impossible from the extreme fullness to detect the edges of the liver. The usual dulness due to the liver was obscured above by the emphysematous lung, and below by the inflated intestines. On placing the stethoscope over that portion of the right side usually occupied by the liver both in the median and in the axillary lines, sibilant and crepitant rales were heard as low as the tenth rib. Posteriorly for a short distance they could detect hepatic dulness, which gradually passed into the dulness due to the kidney. He examined the urine several times, but found not a trace of albumen, and the deposit when examined under the microscope was perfectly free from any casts. They were therefore thrown back on the heart, and perhaps the liver, to explain the dropsy, and he considered it likely that the patient might have cirrhosis of the liver, although it was impossible from the state of the lung and the condition of the abdomen, to arrive at any positive diagnosis, and subsequently he was suddenly attacked with hæmatemesis, when a large quantity of dark blood, having a sour smell and acid reaction, mixed with the contents of the stomach. The treatment adopted was the use of ice, tannic acid, turpentine, whiskey, and beef-tea, the latter being given by enema in consequence of the vomiting. This treatment was not, however, attended with success, and at last he died. On making a post-mortem examination he found the liver did not exhibit any signs of cirrhosis. It was rather larger than normal, and a large quantity of dark clotted blood drained out from the venæ cavæ hepaticæ. On opening the cavity of the thorax they found the heart covered over by the left lung,

which was very much enlarged and remarkably emphysematous. On the edges of the lung large vesicles were seen. He dissected the pleura off very carefully, and found the vesicles were not sub-pleural, but well-marked examples of the result of Laennec's emphysema. The internal surface of the bronchial tubes were found to be intensely congested. In more than one place in the base of the lung portions were found to exhibit that form of solidification due to pulmonary collapse. They found, on examining the heart, the right ventricle was considerably dilated and hypertrophied, as they might have expected, and showing the slow process of death. There was a large fibrinous clot passing up into the pulmonary artery, and also passing back into the right auricle. The musculi papillares were enlarged. There was some thickening of the wall of the left ventricle, and a thickened and roughened condition of the mitral valve. The internal surface of the stomach exhibited a state of intense congestion, but although carefully searched for, no ulcer or abrasion could be detected. It contained a large quantity of dark blood, altered by contact with the gastric juice, as did also the intestines. The spleen was extremely small, being reduced to one quarter of the ordinary size. The two points of greatest interest in the case were the difficulty of diagnosing the presence or absence of cirrhosis of the liver, owing to the condition of the lung, and the occurrence of hæmatemesis in connection with emphysema, without any appreciable contraction of the mitral orifice. It was evident that the obstruction of blood in the lung caused first of all a state of dilation and hypertrophy of the right ventricle, then regurgitation into the right auricle, and a congested state of the venæ cavæ hepaticæ and portal system. As there was a contracted spleen, and no diverticulum for the blood, it naturally caused the congestion of the veins of the mucous membrane of the stomach, and thus produced the hæmatemesis. He had not found many cases of hæmatemesis recorded as connected with emphysema of the lung without cirrhosis of the liver or contraction of the mitral orifice.

SCARLATINA.

Dr. Hewitt said, the specimen he now brought before them, was one having some slight connection with the paper he had the honour of reading before the Society at a former meeting, on the so-called purpuric fever. A child was brought into the City of Dublin Hospital, on Saturday week last, suffering from scarlatina. On the previous Thursday, a distinctly papular rash made its appearance on the skin, not the diffuse rash usual in scarlatina. It was distinctly raised and papular, and of a duller colour than is usual in scarlatina. The tongue was not as characteristic as it usually is, and the throat was not what would be called a bad form of sore throat. It was bright red, there was no livdity about it, nor at that time any ulceration, but the swelling of the tonsils produced some difficulty of breathing. Pulse 147. Temperature 103°, which rose in the evening to 104·6. She was ordered a mixture containing chlorate of potash and Minderer's spirit, and beef-tea and milk for dietary.

On the fifth day of the disease the throat was slightly ulcerated, and it was brushed with a solution of nitrate of silver, the urine was examined, but contained no albumen. She was ordered a combination of chlorate of potash, nitro-muriatic acid, and perchloride of iron ; the throat to be brushed with the solution of nitrate of silver three times daily, and poultices were constantly applied. Pulse 144. Temperature 103·8°.

On the seventh day she became much worse, the urine had diminished in quantity, the pulse had risen, and she exhibited a tendency to a stupid sleepy state. She was ordered to have a warm bath up to the loins for five minutes, and to have small quantities of wine of iron. The child was difficult to manage, for it would not open its mouth, and it necessarily had to be forcibly opened when it was to brush the throat.

On the ninth day the rash had not faded, the tendency to coma had increased and she refused to swallow, and at five o'clock it first exhibited opisthotonos. The occiput was almost drawn to the vertebræ ; the muscles at the back of the neck were very rigid. The ice-bag was applied to the spine from the third cervical vertebræ to the lower dorsal, and at short intervals to the head. Some slight benefit appeared to result for a time from this application, but at half-past ten o'clock the child died. He examined the spinal cord, but it exhibited no exudation of lymph. A quantity of dark blood was found to be contained in the areolar tissue between the theca and the vertebræ.

There were three or four drachms of clear serous fluid in the spinal arachnoid, and it caused the protrusion of the arachnoid through the apertures in the dura mater. No effusion was found in the ventricles of the brain. The substance of the brain was not softened, but there was some congestion of the cerebral veins, especially about the velum interpositum. He thought this case bore on an idea he brought forward on an former occasion, namely that cerebro-spinal fever was not an idiopathic acute inflammation of the spinal cord. He regarded it as indicating the fact that the poison of scarlatina may produce opisthotonos and rigidity of muscles, and that after death there will be no appearance of inflammation, no lymph thrown out, no purulent matter, but merely serum in the arachnoid, and fluid blood in the areolar tissue, between the theca and the vertebræ. It had been too hastily assumed that cerebro-spinal disease was a separate disease. He could conceive that the diseased blood in this case produced the irritation in the spinal centres which ended fatally. It was a remarkable fact, that although there were no purpuric patches before death, the body became plum coloured a few hours after death.

CANCER OF BOTH TESTICLES.

Mr. H. G. Croly exhibited a specimen of firm medullary cancer of both testicles. The patient on admission exhibited symptoms of cancerous cachexia. He was anæmic, and at the angle of the jaw, the submaxillary glands were much enlarged. He had an enormous enlargement of the scrotum. The man was supported freely by stimulants and nourishing diet, but he gradually sank and died the day after admission. The tumour itself was of great firmness; there were cysts in it, filled with the ordinary fluid of hydrocele. Some of the tumour cut like cartilage, although it looked like the fibrous form of cancer. There was very little difference between the right and the left sides. An examination of the viscera discovered cancer deposited in the kidney, stomach, mesentery, and liver. Pounds weight of cancer were found in the cavity of the abdomen.

Dr. Hewitt said the cancerous mass in the mesentery weighed at least eight or nine pounds, but unfortunately the exact weight was not ascertained. One of the kidneys especially was affected, the cancerous matter going through the substance of it, while the cancerous matter went round the other one. The man had but few symptoms of cancer, and was not affected with vomiting. It was that peculiar form of encephaloid cancer before softening, described by Mr. Paget, who says, that where this cancer occurs in the stomach near the pyloric orifice, and remained a long time, it became softened.

Dr. John Barker observed that cancer rarely occurred in both testicles, and the large mass of malignant disease appearing in the rest of the body, was a most remarkable circumstance. He found it presented, under the microscope, the ordinary appearance of encephaloid cancer.

Dr. Fleming said, among many cases of encephaloid disease of the testicle which had come under his notice, he did not remember one in which both testicles were engaged ; and if he mistook not there was hardly a case of the kind on record except one mentioned in the work of Sir Astley Cooper. Scirrhus in the testicle was rare, and on the removal of a testicle for encephaloid disease, the return of the disease was not uncommon; and he should like to know of any case where the second testicle was engaged after the removal of the other one. The surface of this tumour, as represented by the cast, was extremely smooth, whereas they knew that the ordinary cases were nodulated and irregular, an appearance which greatly assisted in diagnosis. The presence of cancer in the kidney was questioned by some, but he had seen specimens where cancer of the kidney existed instertially with minute deposits in every part of the organ. That cancer might engage both testicles must be admitted.

Mr. Collis observed, that this was just the class of case which would make one come to the conclusion arrived at on other grounds with great difficulty—that there was a great deal more analogy between tuberculous disease and cancerous disease, than was at one time allowed by pathologists. It was now universally admitted that the two diseases were compatible, but it was to his mind certain that in disease of the testicle, and in the secondary deposits which arise after disease of the testicle, the combination as it were, or the amalgamation of the two diseases, will be found most frequently. He had seen several cases in which disease of the testicle appeared at first sight to be cancerous, and in which the disease was found after death in many organs, including the liver, the lungs, the mesenteric glands, and in which a careful examination of the material showed its analogies of structure were rather with tubercle than cancer. The cells were rather those

of tubercle than of cancer, and at the same time its general history was rather that of cancer than tubercle. It was just in these doubtful cases, that they were called on to cast aside these names which, however useful as instruments of teaching, could not be applied to every case. He looked on this disease of the testicle as very much of this mixed type in which the structure is much more analogous to tubercle, especially that form of tubercle which conducts itself like cancer. The disease is just as malignant as if it were composed of cells of true cancer. He did not pronounce any opinion on the cells in this instance, not having had an opportunity of examining them, but he threw out this observation, that in disease of the testicle of this type, the two affections of cancer and tubercle seemed to be commingled.

Mr. WHARTON said Mr. Collis's remarks reminded him of an observation made by the late Mr. Houston in that room. In talking of the microscopical anatomy of cancer, he confessed he found great difficulty in distinguishing between scrofulous and cancerous cells. His remarks at the time were not met in the way they should have been, but certainly it now appeared to be well understood that there was much greater identity between scrofula and cancer than was formerly supposed to exist. Every one present had frequently seen cancer in scrofulous subjects. There was a case of the kind in the Meath Hospital the other day, and he had met with similar instances in private practice in which cancer appeared in persons having a scrofulous diathesis. He thought it due to the memory of Mr. Houston to say so much.

A CASE OF PARALYSIS, AND A CASE OF SUPPRESSION OF THE MENSES, TREATED ACCORDING TO DR. CHAPMAN'S METHOD.

Mr. J. H. BENSON said—Mr. President—I have the honour of bringing under the notice of the Society this evening, two cases of disease treated by modifying the temperature of certain regions of the spine.

This mode of treatment, we are all aware, has been tried in a variety of diseases by Dr. John Chapman, of London, and has lately been brought prominently and ably before the profession by that author. However, in Dublin, as far as I am aware, this new method does not seem to have received much attention, at least it has not attracted the notice of this Society, and I, therefore, take the liberty of bringing forward the subject now, with a view to eliciting from the members of the Society, their opinions respecting the value of the introduction, and their experience of its use.

It is now several years since Professor Todd well observed that inflammation was "a deranged nutrition;" but it seems that the same definition might, with good reason, be extended to all disease, if, that is, we accept as a definition of the word nutrition, "the performance of those transformative processes by which new structures are built up, and the old are carried away." Accepting this, it follows, that as the nervous system presides over nutrition in every form throughout the body, it would be natural to expect, that a deranged state of the nervous centres would be followed by a corresponding derangement of nutrition in those parts, over whose nutrition the deranged nervous centres preside. And again, that of diseases, many at least throughout the body are caused primarily, or maintained as disease secondarily, by a certain deranged state of the nervous centres.

In a great number of diseases this derangement, whether primary or secondary, of the nervous centres, is of a nature obscure, and difficult or impossible to detect in the present state of medical science; but in others there seems good reason, chiefly founded on clinical observation, to believe that this derangement is, in the first instance at least, either an excess or a deficiency of functional activity, and that these conditions are due to either hyperæmia or anæmia of the nervous centres, whose activity is exalted or depressed, though direct proof of this latter hypothesis is wanting. If, therefore, we could increase or decrease the supply of blood to the nervous centres, we should, on this hypothesis, at once be able to exalt or depress the functional activity of those centres, and thus, it would seem, be able to control, in a measure, and alter the nutrition of certain parts of the body related to them, or, in other words, have a new therapeutic agent in our hands by which to control *disease*.

This grand object seems to have been accomplished in a very simple way by Dr. Chapman, and by the use of heat or cold to the spine, a great number of diseases seem capable of being successfully treated. This power, moreover, extends not only to nervous diseases, universally so-called, but also to many of those which, previous to his discovery, were never considered to have had any casual relation to a deranged state of the nervous centres. Such for example are bronchitis, diarrhœa, constipation, leucorrhœa, and the usual disorders of menstruation, some skin diseases, and many others.

Whether this therapeutic agent then, is a powerful one or not, is to be determined by experiment; and, I think, that those who give it a fair trial will agree that it is, whatever be their opinion of the soundness of the theories which are involved respecting it.

In several cases of disease I have used this agent, but generally in conjunction with others, and, therefore, though satisfied in my own mind of its influence for good in those cases, I did not report them, for in order that the remedial value of any given general mode of treatment should be fairly tested, it is obviously desirable that the treatment should be used alone. In the two following cases, however, cold to the spine was used successfully, unassisted by any other agent whatever.

In preparing these to lay before the Society, I have endeavoured to avoid entering into tedious details, which were not of importance, as bearing on the special mode of treatment in question.

Case 1.—M. P., æt. 34, residing in a distant country town, was affected with partial hemiplegia of the left side, brought on by cold. Without assistance he could not attempt to walk. In addition to this affection he also suffered from habitual muscular tremors of the left side exclusively. These were chiefly confined to the head, shoulder, and arm; and at irregular intervals of from a few days to a week or ten days, they became much aggravated, almost assuming the form of convulsions. Both extremities of the left side were slightly wasted.

The patient had been suffering in this way for eleven months in the country, and though he was under the care of a skilful physician all that time, his condition did not improve, but was rather becoming steadily worse.

On the 27th May, 1867, he was admitted into the City of Dublin Hospital. He was then treated with bromides, tonics, and other remedies, specially addressed to the nervous system, but at the end of a month he had not made the slightest progress towards recovery. On June 25, by means of Chapman's ice-bag, ice was applied along the greater part of the spinal column, both morning and evening, for half an hour each time. The application felt in no way uncomfortable, but rather the reverse, and next day he reported himself as feeling rather better, and having less of the habitual convulsive tremors.

For the next four days the ice was applied as before. The patient was highly pleased with the application. The spasmodic muscular actions were much less marked—almost absent. All medicinal treatment was now stopped, and was not resumed at any subsequent period.

July 1.—From this date till he left the hospital, on July 20, the ice was applied for one hour every morning and evening.

During this interval of twenty days his condition improved steadily.

The muscular tremors had so far subsided, that he could raise a tumbler, filled with water, to his mouth, several times successfully without spilling the fluid—a feat which he could not have performed for more than a year previously. During this period he had had only one of those attacks, which I have described as aggravations of the habitual muscular tremors. His health, too, and the strength of his limbs, were so far benefitted that he was enabled to go of messages about the house, and assist the nurses and porters in their duties.

On the 20th, as I went off duty, he returned home, with a promise from me, that if his improvement did not continue steadily, I would readmit him after the summer recess. I regret to have to state, however, that before this period had ended, he had again become so seriously ill that he was unable to attempt the tedious journey to Dublin.

Case 2.—M. C., æt. 18, was admitted into the City of Dublin Hospital, in June 1867, suffering from obstinate suppression of the menses, occasioned, suddenly, by having contracted wet feet during one of her menstrual periods. This malady was accompanied by a severe and continuous headache.

A few months after this sudden cessation of the menses, the patient applied for advice at one of the principal hospitals in Dublin. In that institution she remained for nearly four months, and though treated actively the menstrual function was not restored.

When admitted into the City of Dublin Hospital she was again subjected to the usual modes of treatment for such affec-

tions, but without avail. For the last three weeks of her sojourn in hospital, the treatment consisted exclusively in the application of Chapman's ice-bag to the lower dorsal and lumbar regions of the spine, during half-an-hour, twice each day. All other remedial measures were suspended. This treatment also failed to produce the desired effect, though at every application it caused the characteristic pains, and sensations of commencing menstruation. Yet the remedy was not wholly without advantage. From the very first day of its application, the severe headache, from which the patient had suffered for upwards of two months previously, and which nothing was found to remove, or even scarcely benefit, began to diminish, and in three days it had completely left her. At the same time her feet, which had been habitually cold for several months, began to assume a more normal temperature. Before any other marked effect followed, however, the treatment was interrupted, for I went off duty, and the patient left the house.

After this, I did not again see her till the 16th October, when she begged to be readmitted into hospital.

She then informed me that the headache and coldness of the feet had returned very soon after she left the house in July, and had been continuous ever since, with very few and short interruptions. Menstruation, too, had never taken place since that time. During this interval, she had received neither advice nor medicine of any kind.

On her admission, I at once ordered the ice-bag to the lower dorsal and lumbar regions of the spine, for three-quarters of an hour. All other treatment was withheld. After the bag had been applied for about half-an-hour, she complained of obscure pains in the back; objects appeared yellow to her vision; her stomach became nauseated, and after eleven hours she had the great satisfaction of becoming aware that the menstrual flow was taking place. The headache, at the same time, was greatly relieved.

Next day I found the flow was still proceeding, but as it was not so plentiful as on the previous day, I applied the bag to the spine again.

On the third day not a vestige of the headache had remained, a more natural warmth had returned to the lower extremities, and the menstruation was proceeding naturally and without pain, and continued to do so until the expiration of the period usual with the patient—five days. She was then discharged.

A few days after she left the hospital, she called upon me to thank me for the great relief afforded her by the application of the ice-bag, and said she had not felt so perfectly well and happy since she first incurred the wet feet, just a year previously.

On Feb. 5th, about three and a-half months after she had left the hospital the second time, I saw the girl again. She then told me that she had enjoyed excellent health, and that menstruation had proceeded with almost perfect regularity ever since that time.

Thinking that the notes of this case would be acceptible to Dr. Chapman, I enclosed them to him, asking him at the same time for his opinion on the case, and for any suggestions which might occur to him. By return of post I received a most courteous reply, from which I extract the following interesting and instructive comment on the case:—

He says:—"You applied the ice-bag, I observe, during half an hour, twice each day, and at the end of three weeks of treatment, menstruation was not re-established, though the headache was removed, and characteristic menstrual pains were induced. It is probable that had the ice been applied for a longer time, say 45, 60, or even 90 minutes each time, menstruation would have been induced during the first period of treatment. When ice is applied for only a short period, say from 15 to 30 minutes, there is a tendency to subsequent reaction in the form of undue contraction of the peripheral arteries, previously dilated under the temporary influence of the ice.

"In such cases you may find, that though the patient is quite warm during its application, she will shiver in a short time after its removal. In these cases, if you will prolong the application of the ice, shivering will, generally speaking, not follow. Again, during the first few days of treatment, while the spasmodic tendency of the unduly contracted arteries is but partially overcome, they are prone to resume their former habit, soon after the ice has been removed; whereas, a few days later, when it has produced on the vaso-motor nerve-centres a more abiding sedative impression, no symptom of peripheral reaction is observable. It must be borne in mind that arteries which have long been spasmodically contracted, require the prolonged and persistent force of the blood pressing forward within them, in order to re-expand them to their normal size, and, therefore, that which the action of the ice is cumulative, it is necessary to continue its use steadily every day, in many cases for a considerable time, and if there be no special reason to the contrary, straight through the menstrual period, in cases of menstrual suppression not due to so-called 'organic' obstruction.

"Allow me, however, to insist with the utmost emphasis, that the application of the spinal ice-bag must never be so prolonged as to cause internal aching or discomfort, unless of that special kind immediately preluding menstruation. If a patient should become cold while the ice is on, it should be at once removed. A woman, however, may shiver simply because the ice-bag has slipped down over the sacrum. As a rule it is expedient to let it reach no lower than the third lumbar vertebra. In the case of M. C——, the rapid cessation of her headache proved that an increased circulation was speedily induced in the womb, although menstruation did not immediately recur."

These two cases, sir, were treated successfully, as you have seen, by means of the ice-bag, in the hands of one perfectly unprejudiced, after all other means had failed.

There was one important difference, however, between the two, that, whereas, the benefit in the one case was premanent, in the other it was only temporary. Yet I have not the slightest doubt that the case of the paralysis would also have been followed by permanent benefit, though perhaps not so complete as in the other case, had the treatment been sufficiently prolonged.

Dr. Robert McDonnell said he had tried the ice-bag in several cases, and without finding any benefit from it. One of these cases Mr. Fleming saw in Mountjoy Prison some years ago. He was recommended to try the ice-bag by Mr. Spencer Wells, who happened to be present. It was a remarkable case of chorea, at one time affecting the whole of the man's body, but which was then limited to the right arm. He tried the ice-bag for a long time very persistently, without deriving any benefit from it. He tried it afterwards in several cases of a similar nature; one was a remarkable case of a lady who could not keep her head up without being propped beneath the chin. The physiological principle on which the ice-bag is said to act was exceedingly interesting; and he thought it a strange thing that Dr. Chapman had not brought forward a single direct proof that it acted in the way he said it would act. No doubt it sounded very well to say that if you apply an ice-bag on a particular part it will act on the nerves, and thereby produce an effect on the blood-vessels; but had we any proof that cold placed along the spine would produce any lowering of temperature a few inches below the surface. He thought at the present day, nothing in therapeutics was so interesting as the accurate study of those drugs which, acting on involuntary muscles, regulate the supply of blood going to particular parts. This is the way in which strychnine, belladonna, ergot of rye, and other agents act. It was possible that cold might act in the same way, but as yet we had not got any precise facts on the subject. Dr. Chapman had certainly not brought forward any fact in support of his theory. According to it we could produce sleep, by putting cold to the head, with great certainty. It was known that in a condition of sleep the blood-vessels which supply the brain were in a state of contraction. If by putting on an ice-cap that condition of the vessels could be brought about sleep ought to ensue; but however useful ice might be as a sedative, we could not compel sleep by such a process. He (Dr. McDonnell) had himself made some experiments with a view to determine whether cold placed to the surface would lower the temperature at any considerable distance below it. He found that it did so at first, but after a little time there came on reaction, in which the blood-vessels dilate more. He had made the experiment by passing the bulb of the thermometer into a psoas abscess in the thigh, where it could pass in for several inches; and he found when cold was applied to the surface the thermometer fell, but if kept in for a short time it soon recovered itself and went up again as much as ever. A precisely similar effect was found to be produced by cooling the opposite or symmetrical part of the body. It was what occurred in the remarkable experiment mentioned by Mr. W. F. Edward, but the true explanation of which was given by Dr. Brown-Séquard. Suppose a thermometer taken in the right hand, and the bulb of another placed under the tongue and allowed to rise until both came to the same height. If the opposite arm was put into a vessel containing ice, the thermometer held in the hand would sink, while that under the tongue

would remain unaffected. It was quite clear that if the whole of the blood were cooled by plunging the arm into ice, the thermometer under the tongue and that held in the hand would be affected equally. It was from the contraction of the blood-vessels in the symmetrical part of the body, through the medium of reflex nervous influence, that the effect was produced. He had himself made a modification of this experiment. He placed a bat with wings expanded so as to keep one of them under the microscope. He selected a blood-vessel in the wing, and measured it by the micrometer; then placed on the other wing a little mass of ice and salt, and while looking at it under the microscope, the vessel contracted almost to closure. He had shown the same thing where the bulb of the thermometer was run deep into a psoas abscess. If a wet cloth was placed on the other thigh, and ice put upon it, the thermometer would immediately fall, and this plainly occurred from the cooling of the symmetrical part of the body. He only said, as yet, on a subject which was capable of being proved by industry and precision, that not one single fact had been brought forward by Dr. Chapman in support of his theory; and so far as his own experience went, he found that although the application of ice may at first give rise to contraction, it afterwards gave rise to the very opposite of what Dr. Chapman claimed for it. He still thought they stood merely on the threshold of the subject.

Dr. HEWITT said that he concurred with Dr. McDonnell in his views as to the want of precision and scientific accuracy in Dr. Chapman's statements as to the effects of the spinal ice-bag, but he thought that there could be little doubt that in many cases it would prove a powerful agent for the cure of disease. His attention was directed to the remedy by the facts observed by his colleague, Dr. John H. Benson, and he confessed until that time he had been incredulous as to the effects of Dr. Chapman's treatment. He had used the ice-bag in a case of delirium tremens after capsicum had failed and tartar emetic and opium had seemed to do harm, and found that it checked perspiration, cured the tremors, and produced sleep almost immediately. He hoped to bring this case under the notice of the Medical Society of the College of Physicians, and believed that he was the first to use ice to the spine for delirium tremens. The results in this case were precisely those attributed to the remedy by Dr. Chapman, and he thought they were fraught with interest.

Mr. WHARTON asked Dr. Benson in what state the menstrual secretion was before this girl was brought under treatment.

Dr. BENSON replied that up to the time of her first having got wet feet the menstruation was perfectly regular. With regard to Dr. McDonnell's observations, the same thing struck him also, and he made allusion to it in his paper, that proof was wanting; but facts were stubborn things, and in some cases facts did bear out Dr. Chapman's treatment, whether he explained them rightly or otherwise. Dr. McDonnell spoke about applying cold to the head to produce sleep, by contracting the arteries. If Dr. Chapman wanted to contract the arteries of the brain he would apply heat to the nape to stimulate the sympathetic nerves and give contractile energy to the muscles surrounding the artery. As to reaction, Dr. Chapman acknowledged that it would take place if the ice-bag were put on only for a short time; but if kept on long enough, he said, there would be no reaction, and it would produce the desired effect.

The Society adjourned.

MEDICAL SOCIETY OF LONDON.

MARCH 16TH, 1868.

Dr. B. W. RICHARDSON, F.R.S., President, in the Chair.

A VOTE of thanks to the retiring President, H. Smith, Esq., was proposed by Mr. Hunt, seconded by Dr. Thorowgood, and carried with acclamation.

Dr. RICHARDSON delivered a most interesting address. After congratulating the Society on its present position, and suggesting some changes with a view to its increased usefulness, he enunciated the conclusions to which his recent researches had led him, as "The Laws of Attraction and Resistance of the Nervous System." He contended that the nervous organism is not a centre for the constant liberation of force, but a centre in which force can be returned or transmuted. The prime conductor of internal force in the body is the blood.

In answer to a request from the Fellows, the President announced that his observations should be printed so that the propositions might be submitted *seriatim* to criticism.

Mr. HENRY SMITH exhibited a specimen showing a hard cancerous growth involving the prepuce and penis, which he had removed from a patient, aged 55. The patient had been under the care of two other practitioners who had been treating the disease as of a simple non-malignant character. Mr. Smith gave it as his opinion that the only course to be pursued was to amputate the affected part. The patient was going on most satisfactorily.

A long and interesting discussion ensued, especially on the possibility of the transmission of cancer by contact, the opinion of the large majority being that the disease was not so transmissable.

Dr. W. H. DAY narrated a case of inflammation of the cœcum caused by sea-sickness. He considered the case to have been one where the portion of bowel had been considerably loaded, and the violent vomiting on board ship had set up inflammatory action, which at one time threatened to extend. It is still under treatment.

In the discussion which ensued, Dr. Cholmley, Dr. Hare, Dr. Sansom, and Mr. Hunt, took part.

In answer to a question from the President, Dr Leared narrated a case of death from sea-sickness.

Dr. LEARED made a communication on a case of inflammation of the alveolar periosteum, which had at once subsided on the occurrence of an attack of gout.

The PRESIDENT mentioned a similar case, and a discussion ensued.

Correspondence.

CONDY'S FLUID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As an experimental chemist I have, for the last three years, used and closely watched the effects of permanganate of potash (Condy's fluid) as a cleansing and disinfecting agent; and when a man, like Dr. William Proctor, is seemingly uninformed as to its *practical uses*, it is perhaps time to make known that (if used according to the simple directions) it is a much cheaper, more agreeable, and better purifier for medical and general purposes than other articles; and that so far from destroying clothing or furniture, it is one of the very best means of purifying either, or improving them in appearance. Its daily use in the nursery will convince any practical man that it materially conduces to the health and appearance of the children, rendering the room at all times sweet and wholesome, a fact that cannot be too widely known.—I enclose my card, and am, sir, A PRACTICAL CHEMIST.

CONSANGUINITY

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The interesting letter in your last number on "Consanguinity," prompts me to write a line thereanent. Some time ago a society in America was circulating queries on the subject, in order to amass statistics, but I have not heard the result. Perhaps some of your correspondents in the western hemisphere can enlighten us as to that society's proceedings.

C. G. seems to have hit the mark on several points, and his letter is, therefore, of great value. The facts he names are of such interest, that one can only wish he had given us a further account of the topography and natural history of the valley of cousins, as we may call the uncivilized, outlandish country he has described. If he can supplement his letter, I hope you will give him space to do so.

Very naïvely does he remark, "we must first find two members of one family perfectly free," &c., a search for which, in a country like this, would not be likely to be successful. I re-echo this. "First catch your hare."—I am, &c.,

A. B

DISLOCATION OF THE HEAD OF THE FEMUR ON THE DORSUM OF THE ILIUM, REDUCED BY MANIPULATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much pleased to read in your last number, in the clinical reports by Mr. Edward Hamilton, the case of dislocation of the head of the femur on the dorsum iliac, reduced by manipulation.

Some twenty years ago (I do not write for priority), as surgeon to the South Hants Infirmary, a similar case came under my charge, which foiled my efforts at reduction in the usual way by pulleys—when it occurred to me that by maintaining the shaft of the femur in a favourable position, and throwing it backward its head would be elevated over the edge of the acetabulum, and fall into its normal position. I therefore placed the patient on his back, and while an assistant held the pelvis steady, I drew up the foot of the displaced limb (the left) to the inner side of the other knee, and resting on the bed. Thus the knee was flexed, and this movement brought the neck of the femur to a right angle with the ilium, on which its head rested, behind the articulation. Placing my right hand over this part of the bone, more with a view of ascertaining that this relative position was preserved, than assisting the reduction, I grasped the bent knee with my left hand, and abducted the limb when the head of the bone started forward, easily into its natural cavity.

The mechanism of the operation is easily demonstrated in the skeleton.

I sent a statement of the case to the *Lancet* and the *Journal of the Provincial Medical and Surgical Association*, at the time, and it is referred to in "Fergusson's Practical Surgery." I mentioned the plan to several surgeons for trial in such cases, and I am happy to find it has been successful in the hands of the other practitioners named in the report.—I remain, sir, your obedient servant,

Southampton. H. CLARK, M.D., M.R.C.S., F.S.A.

"HOSPITAL APPOINTMENTS IN DUBLIN."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was only this evening I noticed in your impression of the 18th inst. the article headed "Hospital Appointments in Dublin."

With reference to that portion of it which relates to myself, I have the pleasure of informing you that I *have* been appointed one of the Examiners in Surgery in the University of Dublin.—I am, sir, your obedient servant, J. H. WHARTON.

28th March, 1868.

"PURCHASE SYSTEM" IN DUBLIN HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The meaning of my letter published in *Saunders* of the 12th ultimo has not been correctly understood by all its readers in one very important particular. It was not my wish to condemn in any way the purchasing of the resignations of hospital men. In favour of what is known in Dublin as the "purchase system" much can with justice be urged. Even many who do not approve of it acknowledge that where carried out fairly and legitimately it has proved the most available remedy for worse evils. But on the occasion alluded to *two-thirds* of an hospital staff contemplating speedy retirement sought to play out what a letter signed "T. O. B." in *Saunders* of April 4th designates a "pretty little piece of business." Hence the *denouement*—not in censure of the "purchase system," but of its attempted gross abuse.—Yours, &c.,

"ONE OF THE GOVERNORS OF MERCER'S HOSPITAL."

Medical News.

MISS GARRETT.—"A duly registered Practitioner." The following curious entry occurs in page 163 of the *Medical Register* for 1868, (just published):—

"1866, Sep. 1.—Garrett, Elizabeth, 20, Upper Berkley-street, Portman-square, London, W.; lic. soc. apoth. Lond. 1865."

VACCINATION IN SCOTLAND.—The third annual report of the Registrar-General of Scotland, made in pursuance of the Vaccination Act of 1863, shows that upwards of 96 per cent. of the surviving children of 1866 have been vaccinated. 113,730 births were registered in the year 1866, but 9,433 died unvaccinated, leaving 104,297 surviving. Of this number 96·27 per cent. were successfully vaccinated; 0·56 per cent. had their vaccination postponed from ill-health or other causes; 0·56 per cent. were found insusceptible of vaccination, many of them from having been already vaccinated, and all being equally insusceptible of small-pox; the remaining 2·61 per cent. are returned as removed from the district before vaccination, or otherwise not accounted for. Little more than 3 per cent. of the surviving children of 1866 are unprotected by vaccination. In some of the islands a regularly appointed vaccinator can attend only once in two years. So far as at present appears, the Vaccination Act has been successful. Never since civil registration began in Scotland has small-pox been so rare as during the past three years when the Vaccination Act was in full operation.

BRANCH MEDICAL COUNCIL (IRELAND)—List of Entries for the month of March, 1868:—Thomas Mannon Woodley Ahearne, 126, George's-street, Cork, L.R.C.P.Edin., 1867; L.R.C.S.Edin., 1867. Ambrose Bodkin Kearney, Cliften, Co. Galway, L.R.C.P.Edin., 1867; L.R.C.S.Edin., 1867. Edward Hadden, Maryborough, Queen's County, L.R.C.S.Irel. 1868. Henry Harris Langstaff, Athlone, Co. Roscommon, M.B., 1867, and M.Ch., 1868, Univ. Dubl.

THE Dublin Obstetrical Society will meet in the College of Physicians on Saturday next, April 11th. The following communications will be made:—1. T. E. Beatty, "Case of Fibro-cystic Tumour of the Vagina." 2. R. W. Harley, "Case of Gonorrheal Rheumatism after Parturition." 3. G. H. Kidd "On a Rare Form of Prolapse of the Uterus cured by a Plastic Operation."

QUARANTINE RESTRICTIONS IN THE WEST INDIES.—The *Jamaica Gleaner* of March 10th says:—"All vessels touching at St. Thomas are prevented entering any harbour in Porto Rico, and in the event of their touching off the port a penalty of £500 will be incurred if they do not proceed to sea within one hour. Even communication for the supply of water is denied. At Barbadoes the quarantine regulations are 20 days; at Demerara, 12; and at St. Croix and Tortola no communication is allowed, as a *cordon sanitaire* has been established. In Jamaica, in consequence of representations from Mr. Lamb, the British Consul at St. Thomas, his Excellency the Governor, with the advice of the Central Board of Health, has directed that stringent measures should be adopted here to prevent the possibility of the introduction of infectious diseases. The expected packet will be required to state from what vessels and hulks she received coals, when these left St. Thomas, and if any communication had taken place between them and St. Thomas from the time of their departure. Any unsatisfactory answer will render the ship liable to quarantine.

NOTICES TO CORRESPONDENTS.

Mr. E. S., Sandgate.—Altered to make it more suitable.

MEDICAL SOCIETY OF LONDON.—On Monday next Mr. Bryant reads a paper "On some Affections of the Breast Simulating Cancer," and Dr. Oppert, one on "Existing Hospitals."

A VOLUNTEER MEDICAL OFFICER.—It is not a necessity, but advisable that you should do so. See letter in our correspondence columns from a member of the force on the subject.

M. S., Liverpool.—Declined for obvious reasons.

SURGICAL APPLIANCES.—Sorry we cannot afford you space. You advance on no new field, and we cannot find room for constant repetitions of other men's ideas.

Correspondents will accept our thanks for the following newspapers:—East London Observer, Hobart Town Mercury, Tasmanian Times, Public Health, Hastings News, Worcester Chronicle, Liverpool Mercury, &c.

J. O. C., M.D., Woolwich, is thanked for the following kind expressions which we extract from his letter as a specimen of others we are daily receiving:—"I am pleased that the leaves are cut, as it saves me much time and trouble. I also wish to say that I am altogether satisfied with THE MEDICAL PRESS AND CIRCULAR."

MEDICAL OFFICERS OF VOLUNTEER CORPS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Understanding that there was a numerous attendance of surgeons of the different volunteer corps the other day at the West End, for the purpose of considering their position and responsibilities on field-days, allow me to say, as an old staff-surgeon, that I cannot see why a surgeon of volunteers is not to be distinguished on the field by wearing the cocked hat, the same as an officer of the line is obliged to do; but I believe more than half the surgeons of the volunteers wear the shako minus the tuft, and if their services are required, it is difficult for any man who falls out to recognise his surgeon.—I am, sir, your obedient servant, AN OLD VOLUNTEER SURGEON.

Kingston-on-Thames.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is there any way of making a person answerable for "Quack Treatment" of a dispensary patient. *Under medical treatment at time of such interference*, a patient of mine has been injuriously "quacked," and but for timely aid, might have owed his death, in a great measure, if not entirely, to the interference of a person professing ability to cure disease.—Yours obediently, A SUBSCRIBER.

[OUR correspondent suffers under a grievance against which he has no redress. It is competent for the patient to prosecute for malpraxis, and to sustain his case by the evidence of his medical attendant, but no action could be maintained by the physician in consequence of interference for which the patient alone was responsible.]

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

THE SUMMER SESSION commences on FRIDAY, May 1st.

LECTURES.

Midwifery	Dr. John Clarke.
Materia Medica	Dr. Dickinson.
Practical Chemistry	Dr. Noad, F.R.S.
Botany	Dr. Maxwell Masters.
Medical Jurisprudence	Dr. Wadham.
Pathology	Dr. J. W. Ogle.
Comparative Anatomy	Dr. Bright.
Dental Surgery	Mr. Vasey.

On the payment of a compounding fee of 100 guineas, a pupil becomes perpetual to the practice of the Physicians and Surgeons and to all Lectures, may compete for all Prizes, Exhibitions, and for the Office of House-Physician, House-Surgeon, Medical and Surgical Registrar, and may become Clinical Clerk and Dresser for two periods of three months each.

On the payment of 40 guineas at the commencement of the first Summer Session, 40 guineas at the commencement of the second Summer Session, and 10 guineas for each additional year, a pupil will be admitted to the Hospital Practice and Lectures required for Examination by the various Examining bodies.

Gentlemen can enter to the Hospital Practice and Lectures separately, or to any one Course of Lectures.

The Hospital contains 350 beds. Clinical Lectures are delivered by the Physicians and Surgeons every week.

A MATERNITY DEPARTMENT, for the delivery of married lying-in women at their own homes, is established at the hospital, and a ward is devoted to the reception of women suffering under diseases peculiar to the sex.

The following Prizes will be awarded at the termination of the Session:—

Sir Charles Clarke's Prize for Good Conduct.
The Thompson Medal.
Sir Benjamin Brodie's Clinical Prize in Surgery.
The Henry Charles Johnson Memorial Prize in Anatomy.

A General Examination will be held at the end of the Session, and a Certificate of Proficiency given to each pupil who passes to the satisfaction of the Examiners, and the following Prizes to the most distinguished, viz.:—

A Prize of Ten Guineas to Pupils in their First Year.
A Prize of Ten Guineas to Pupils in their Second Year.
A Prize of Ten Guineas to Pupils in their Third Year.

Further information may be obtained from Dr. Barclay, the Treasurer of the School; Mr. Holmes, Dean of the School; or from any of the Lecturers at the Hospital.

ROYAL COLLEGE OF SURGEONS.
SCHOOL OF SURGERY.

THE SUMMER SESSION commenced on MONDAY, the 6th April, and includes the following Courses of instruction:—

Botany	Dr. MINCHIN.
Practical Chemistry	Dr. W. BARKER.
Medical Jurisprudence	Dr. GEOGHEGAN.
Materia Medica	Mr. MACNAMARA.
Midwifery	Dr. SAWYER.

Premiums will be awarded at the close of the Session.

By Order,
JOHN BRENNEN, Registrar.

CARMICHAEL SCHOOL OF MEDICINE,
NORTH BRUNSWICK-STREET.

THE SUMMER SESSION will commence on WEDNESDAY, April 15, 1868.

Practical Chemistry	Dr. E. Davy.
Materia Medica	Dr. Frazer.
Medical Jurisprudence	Dr. O'Reilly.
Botany	Dr. Campbell.

FEE FOR EACH OF THE ABOVE COURSES, £3, 3s.

CARMICHAEL MEDALS AND PRIZES will be awarded in each of the Summer Classes.

For particulars apply to Dr. CORLEY, *Registrar*, 14, *Summer-hill, or at the School.*

LEDWICH SCHOOL OF MEDICINE.
SUMMER SESSION, 1868.

THE SUMMER COURSE commenced on MONDAY, April 6, and includes the following course of Lectures.

Materia Medica	Dr. McDowell.
Practical Chemistry	Dr. Cameron. Dr. Reynolds.
Midwifery	Dr. Ringland.
Forensic Medicine	Dr. Travers.
Botany	Dr. Maunsell.

Prospectuses and full particulars at the School.

EDWARD LEDWICH, Secretary, 7 Harcourt-street.

April, 1868.

DR. STEEVENS' HOSPITAL AND MEDICAL COLLEGE, DUBLIN.

THE SUMMER SESSION, 1868, commenced on MONDAY, APRIL 6TH, and includes the following Courses of Instruction:—

CLINICAL MEDICINE.	CHEMISTRY.
CLINICAL SURGERY.	JURISPRUDENCE.
MIDWIFERY.	BOTANY.
PRACTICAL MIDWIFERY.	OPERATIVE SURGERY, AND PATHOLOGY.
MATERIA MEDICA.	

Particulars may be learned from Dr. SWAN, Resident Surgeon at the Hospital, or from

EDWARD HAMILTON, Hon. Secretary.
120, Stephen's-green, W.

SURGICAL SOCIETY OF IRELAND.
Meeting of the 17th postponed to the 24th inst.

THE Next Meeting of the Society for the present Session will be held in the Albert Hall, Royal College of Surgeons, on FRIDAY EVENING, the 24th inst.

Chair to be taken at half-past Eight o'Clock precisely.

By Order,
CHAS. BENSON, } Hon.
B. WILLS RICHARDSON, } Secs.

BRITON MEDICAL AND GENERAL LIFE ASSOCIATION.

Chief Office—429, Strand, London.
City Branch—1, Princes-street, Bank, London.

TRUSTEES.

Lieut.-Gen. Sir. J. E. Dupuis, K.C.B.	R. Partridge, Esq., F.R.S.
Sir James Duke, Bart.	Francis Webb, Esq.
Sir W. Ferguson, Bart, F.R.S.	W. Tyler Smith, M.D.
	Millis Coventry, Esq.

DIRECTORS.

Chairman of the Board—FRANCIS WEBB, Esq.
Deputy Chairman—W. TYLER SMITH, M.D.

Wilson Ancell, Esq.	Thomas B. Jones, Esq.
George Chapman, Esq.	E. James Oliver, Esq.
Millis Coventry, Esq.	Samuel Richards, M.D.
William Hamilton, Esq., R.N.	E. H. Sieveking, M.D.

Consulting Physicians—James Copland, M.D., F.R.S.; George Burrows, M.D., F.R.S.
Consulting Surgeon—Sir. J. Ranald Martin, C.B., F.R.S.

MEDICAL EXAMINERS.

F. Le Gros Clark, F.R.C.S.	William Scovell Savory, F.R.S.
F. J. Farre, M.D., F.L.S.	Thomas H. Wakley, F.R.C.S.
W. J. Little, M.D.	

Standing Counsel—Thomas W. Greene, Q.C.
Solicitors—Messrs. Bell, Steward, and Lloyd.
Bankers—The Union Bank of London, Charing-cross Branch; Messrs. Dimsdale, Drewett, Fowler, and Barnard, 50, Cornhill.
Actuary and Secretary—John Messent, F.I.A., F.S.S.

THE ANNUAL INCOME exceeds £230,000, and is increasing by £25,000 per annum.

By the important improvement in the distribution of profits introduced by this Association (known as the Briton feature), policies on the ordinary rate of premium become payable to the assured himself on his attaining an advanced age, or at his death, should that occur sooner. When the policy is for £200 or upwards, and the assured life is not under 25 years of age, whole world leave of travel and residence is granted on payment of one small sum, determined in amount by the occupation and circumstances of the applicant, and the policy is made absolutely indisputable and indefeasible from the date of its issue.

The rapid accession of the Company's new business during the past ten years will be readily seen from the following table, divided into quinquennial periods:—

Quinquennial Period.	No. of Proposals.	Amount Proposed.	No. of Policies Issued.	Amount assured.	Amount of Annual Premiums.
1857 to 1861 inclusive.	10,799	£2,100,268	7,799	£1,492,405	£46,117 0 10
1862 to 1866 inclusive.	16,401	4,277,918	12,521	3,283,782	105,162 0 0

Prospectuses and every information may be had on application to JOHN MESSENT, F.I.A., F.S.S.

N.B.—*Special Advantages allowed to qualified Medical Practitioners upon effecting or introducing Assurances.*

JAMES'S FEVER POWDER, 4s. 6d. per bottle, Packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

THE CANTOR LECTURES AT THE SOCIETY OF ARTS.

Dr. LETHEBY'S THIRD LECTURE ON FOOD.

CONSTRUCTION OF DIETARIES: PREPARATION AND CULINARY TREATMENT OF FOODS.

(Continued from page 302).

In the treatment of vegetable foods it is important to remember, that all corky and woody tissues, as the skins of fruits, tubers and cereals, are quite indigestible, and that in consequence of their irritating action they hurry food through the alimentary canal, and so occasion waste. It is necessary, therefore, that all such tissues should be removed as completely as possible.

When it is required to obtain the starchy or farinaceous matters of vegetables, one or other of the following processes is followed:—

(a). The material is pulped or crushed, and diffused through a considerable volume of cold water. It is then strained and allowed to stand until the farina or starch subsides.

(b). Or it is allowed to pass into a state of putrefactive decomposition, whereby the albuminous matter, as the gluten, &c., decay and leave the starch untouched.

(c). Or it is subjected to the action of a weak alkaline solution, generally of caustic soda, which dissolves the gluten, and allows the starch to subside. The gluten thus dissolved may be again recovered by neutralizing the alkaline solution with acid, and collecting the precipitated gluten, as in the processes of Durand, and others.

I have already explained that in the treatment of the ground meal of wheat and other grain, the bran and coarser kinds of flour are separated by sieves of different degrees of fineness, and that in this manner about eight or nine varieties of product are obtained, as *biscuit flour, best or fine households, seconds, tails, fine sharps or middlings, coarse sharps, fine pollard, coarse pollard,* and *long bran,* the proportions of these from ordinary brown meal will vary according to circumstances, but processes have been invented, as by M. Mège Mouries, M. D'Arblay, and others, whereby the yield of fine flour is increased to from 86 to 88 per cent. of the grain, and by which the quantity of gluten is also regulated.

When the flour is rich in gluten, as in the case of the hard wheats of Sicily, Russia, Sardinia, and Egypt, they are well suited for the manufacture of certain granular powders and dried pastes, which are known as *Semola, Semolina, Soujee, Mannacroup, Maccaroni, Vermicelli,* and *Cagliari paste.* The last three are generally imported from Naples or Genoa, where they are made from a highly glutenous wheaten flour by kneading it into a thin dough or tenacious paste, and then forcing it through holes or slits in a metallic plane. In this way the several varieties of *pipe, celery,* and *ribbon maccaroni* are obtained; and the fancy forms of it, called *Cagliari paste,* which are in the shape of stars, rings, Maltese crosses, &c., are produced by stamps. All these varieties of paw wheaten paste are cooked by boiling or baking, and are associated with soup or beef-tea, or milk, or are mixed with eggs, cheese, &c.

The best variety of flour for bread is that which contains less gluten than the preceding, as from 8 to 10 per cent. of it, instead of from 12 to 14, or 15. Dantzic flour, and soft Spanish, as well as the American called Genessee, are the best examples of it, and are highly esteemed by bakers on account of the fine quality of bread which is procurable from them; the richer varieties of hard glutenous wheat being used only to impart strength to weak and inferior descriptions of flour.

Bread, which is the most important preparation of flour, owes its value as an article of diet to a good and equable vesiculation of the dough, the vesiculation being effected by the diffusion of small bubbles of carbonic acid gas throughout its substance; and, as this vesiculation can only take place in a proper manner when the gluten of the flour is in sufficient quantity, and of good quality, it is to some extent a test of the goodness of the meal. Those flours which contain too little gluten, or gluten which is deficient of strength, cannot be vesiculated into bread. This is the case with almost every description of flour, excepting that of wheat and rye.

The most common, and also the most ancient method of vesiculating bread is by fermentation; and the process is not very different from what it was in very early times, when we were told that "a little leaven leaveneth the whole lump." Yeast of some sort—as brewer's yeast; or patent yeast, prepared from infusion of malt and hops; or German yeast, which is the solid residue of the yeast produced by the fermentation of rye for making Hollands; or baker's yeast, which is made from potatoes and flour; or leaven, which is old dough in a state of fermentation, is mixed

with the flour or dough, which soon begins to ferment by the action of the yeast fungus *(micoderma cerevisiæ)* on the sugar of the flour. Carbonic acid is thus produced; and by being diffused through the substance of the dough it vesiculates it, and causes it to rise or swell. The most usual practice with the baker is somewhat as follows:—A special ferment is prepared from mealy potatoes (technically called *fruit)* by boiling them in water, mashing them, and allowing them to cool to a temperature of about 80° of Fahrenheit. Yeast is then added to them, together with a little flour to hasten the fermentation. In three or four hours, at a proper temperature (as from 80° to 90° F.), the whole mass is generally in a state of active fermentation, with a sort of cauliflower head. It is then diluted with water and strained, and is mixed with sufficient flour to make a rather thin dough, which in about five hours rises to a fine *sponge*. This is again diluted with water containing salt, and is worked with the necessary quantity of flour into dough, and allowed to stand for two or three hours, when it rises, and is in a fit condition to be baked into loaves.

It can hardly be said that the potatoes are an adulteration in this case, for they do not ever amount to more than six lbs. to a sack of flour, which makes about 380 lbs. of bread, or 95 four-pound loaves. The salt is added to the extent of about four lbs. or more to a sack of flour, the proportions being regulated according to circumstances, for the object of it is to improve the quality of the loaf as regards whiteness, firmness, and flavour.

There is, no doubt, a slight loss of nutritive matters by this mode of vesiculation, for a small portion of the sugar of the flour is converted into alcohol and carbonic acid, but the quantity is so inconsiderable as to be undeserving of notice. The advantage of the process, however, is that it is an excellent test of the quality of the flour; for weak flour, or flour that has been injured by germination, or by keeping, will not stand the action of yeast, but will be either ropy, or sticky, or heavy, when baked into bread.

Another method of vesiculation is to generate carbonic acid in the dough by the action of an acid on bicarbonate of soda. Dr. Whiting's process, which was patented in 1836, was to mix the carbonate of soda with the flour, and then to act on it with a proper proportion of muriatic acid added to the water. He used from 350 to 500 grains of carbonate of soda to 7 lbs. of flour, and to this he added 2¾ pints of water charged with from 420 to 560 grains of muriatic acid. Other proportions are used by bakers who make unfermented bread; but in all cases the proportions should be such as to form common salt (which is the product of the action of muriatic acid on carbonate of soda)—the carbonic acid being liberated in the substance of the dough. Care should be taken that the muriatic acid is pure, for that found in commerce is generally highly charged with arsenic.

In 1845, another acid was patented instead of muriatic—namely, tartaric; and the various preparations called *baking-powders, custard-powders, egg-powders*, &c., are nothing but mixtures of tartaric acid and carbonate of soda, with a little farinaceous matter, the common proportions being 1 part of tartaric acid, 2 of carbonate of soda, and 4 of potato-flour or other dry starch, with a little turmeric powder to give it a rich yellow tint. When this is mixed with flour and wetted, it effervesces, as in the case of a common seidlitz powder, and so diffuses the carbonic acid through the dough.

Very lately, Mr. McDougall has proposed the use of phosphoric acid, as a mere natural constituent of food than the preceding, and this with an alkaline carbonate, forms the preparation which is known as *phosphatic yeast*.

A third process, which is now extensively used in the vesiculation of bread, is that of Dr. Dauglish, and by which the bread called *ærated* bread is obtained. It consists in the addition of a solution of carbonic acid in water to flour under pressure. The mixture is made in a closed air-tight vessel, in which the dough is well kneaded by machinery, and directly the outlet of the vessel is opened and the pressure thus removed, the gas escapes from the water, as in the case of an uncorked bottle of soda-water, and expands into little bubbles within the substance of the dough. By its expansion, also, it forces itself out of the mixing chamber, and rises into a spongy dough.

In all cases, however, where carbonic acid is generated within the dough by other processes than fermentation, the dough must be baked immediately or it will fall, and the loaf be heavy. Various contrivances have been suggested for helping the process of kneading, which is laborious, and sometimes not altogether cleanly work. Mr. Steven's hand-machine appears to accomplish this very well. It is in use in the Holborn union, where about 5633 lbs. of bread are made every week by one man and two boys; and they contrive to make ninety-six four-pound loaves out of every sack of flour (280 lbs.). The materials used on the average of a whole year being as follows:—

PROPORTIONS PER WEEK.

Flour	4129 lbs.	Which produce 5633 lbs. of bread, or 1408 four lb. quartern loaves.
Cones	140 „	
Potatoes	168 „	
Salt	68 „	
Malt	13 „	
Hops	1½ „	

The potatoes, the malt, and the hops are for the purpose of making the yeast or ferment for the bread.

But, by whatever process bread is made, it is necessary to observe certain precautions to ensure the production of a good loaf.

1st.—The flour should be from sound grain sufficiently rich in good gluten.

2nd.—The yeast should be sweet, and should show a lively action in the sponge.

3rd.—The dough should be well kneaded to insure the thorough diffusion of the gas, and to give toughness to the gluten.

4th.—The salt should be used in such proportion as to regulate the fermentation, and give firmness to the gluten, whiteness to the bread, and a good flavour.

5th.—The baking should be so managed as to insure the thorough heating of the loaf to the temperature of at least 212° of Fahrenheit, in order that the insoluble starch may be changed by the heat into soluble dextrine; and the crust should be light coloured and thin. This is best effected when loaves are baked singly, as on the Continent, and not in batches, as with us; for in the last case, the top and bottom crusts are thick and hard, and are frequently scorched, while the interior of the loaf is doughy and underdone.

Specimens of the different kinds of bread of England and the Continent are upon the table; and you will notice the dark colour of the *rye-bread* of Europe. I am indebted for these illustrations to the kindness of Mr. Twining, who has liberally placed the valuable collection of foods in his museum at our disposal. Here, also, is a sample of rye-bread supplied by Mr. William Ray Smee, who, in the interest of the poor, has had it made according to the formula of the Board of Agriculture of 1795. It consists of one part of rice and four parts of rye ground together and sifted in the usual manner. The meal is then made into dough with yeast; and when fermented is baked in the form of long rolls. The bread is very dark, like all rye-bread, and has a close texture, but it is agreeable to the palate, and is very nutritious. The great recommendation of it is its cheapness, for it can be made at less than a penny a pound, and is therefore a very suitable bread for the poor.

Those flours which do not contain sufficient gluten of the proper quality for fermentation or vesiculation, as barley-meal, oat-meal, Indian-meal, and the flour of peas and lentils, are best cooked by baking them in the form of cakes or biscuits—a practice which is as ancient as the time of the Patriarchs, when during the Passover they were commanded to eat unleavened bread. The chief food of the common people of Rome was a heavy kind of unleavened bread, like the present *polenta* of the Italians,

which is made of Indian meal and cheese. As in former time, biscuits and unfermented cakes are made from meal or flour mixed with water and baked; but the texture of the substance is close, and it is not easy of digestion unless it is thoroughly disintegrated. When biscuits are lightened by means of egg and sugar, with a little butter, they are much more digestible; and they are still more so when they are vesiculated or puffed up by means of a small quantity of carbonate of ammonia, as in the case of *cracknells* and *Victoria biscuits*.

The so-called *farinaceous foods* for infants are only baked flour, sometimes sweetened with sugar. The flour must be baked until it acquires a light brown colour, the temperature being about 400° or 450° of Fahrenheit. The granules of starch are then disintegrated and converted into a soluble substance, named *dextrin* — which by a further process of cooking or boiling, as in making pap, forms, when properly sweetened, a very excellent food for children. *Tops* and *bottoms* owe their value to the same circumstance—namely, that the farinaceous matter, which is so indigestible with infants, is broken up by baking into soluble dextrin.

All varieties of meals and arrowroots are easily cooked by stirring them into boiling water, or boiling milk, until they have the consistence of gruel or hasty pudding, and then boiling for a few minutes. In the case of Indian meal, rice, split-peas, lentils, and haricots, the boiling should be continued for a considerable time, and the whole grain should be previously steeped in water for many hours; for the starch and cellulose of these vegetables are not digestible, unless they are thoroughly disintegrated by cooking. It may be said, indeed, that all vegetables with dense tissues require prolonged boiling to cook them, for cellulose is not capable of digestion by man unless it is broken up by the action of heat—even starch is likely to pass through the alimentary canal unchanged, if it be not rendered soluble by fermentation or cooking. It is an important question, whether in utilizing starchy foods, it may not be advantageous to help their transformation, by allowing the grain to germinate to some extent, as in the process of malting, when the starch is changed into sugar. Mr. Lawes has examined this question, and has concluded, from his experiments on stock, that in the case of pigs and bullocks the fattening effect of the grain is not increased; but it may be different with the human stomach, where the transformation power is not nearly so active as with lower animals. Here, in fact, is an example of it: the food which Liebig recommends for infants is a preparation of malt with wheaten-flour and milk, to which a little bicarbonate of potash has been added; and the reputation of it in Germany, as an article of diet for children, is considerable. The preparation is made by mixing one ounce of wheaten-flour with ten ounces of milk, and boiling for three or four minutes; then removing from the fire and allowing it to cool a little. One ounce of malt powder previously mixed with 15 grains of bicarbonate of potash, and two ounces of water, are then stirred into it; and the vessel being covered is allowed to stand for an hour and a-half, at a temperature of from 100° to 150° Fahrenheit. It is then put once more upon the fire and gently boiled for a few minutes. Lastly, it is carefully strained to remove any particles of husk, and then it is fit for the child's food. The composition of the food, according to Liebig, is as follows :—

	Plastic matter. oz.	Carbonaceous matter. oz.
10 oz. milk	0·40	1·00
1 oz. wheat-flour ...	0·14	0·74
1 oz. malt-flour	0·07	0·58
	0·61	2·32

The relation of the plastic to the carbonaceous being as 1 to 3·8, which is the right proportion for the food of children.

The effect of the malt-flour is to transform the starch into glucose, and thus the mixture gets thinner and sweeter as it stands; and the bicarbonate of potash is added to facilitate the change, and to neutralize the acid constituents of the flour and malt.

Liebig's extract of malt is another such preparation for a quick assimilation of starchy matters.

Vegetable substances are occasionally fermented, either for the purpose of increasing the relative amount of glutenous matter, or for the purpose of rendering them acid. Potatoes, for example, as well as barley, wheat, and rye, leave a residuum after fermentation, which contains more gluten than the original substance, in consequence of the transformation of sugar and starch into alcohol; and although the residuum is coarse, and is hardly suited for human consumption, yet it is an excellent food for cattle: in fact in Germany it is often eaten by the poor.

When the process is carried still further, and the mass acquires an acid property in consequence of the formation of acetic, butyric, and lactic acids, various sour preparations are obtained which are no doubt useful in assisting the digestion of other foods. The ancient Romans had many such fermented substances which were not unlike the *Sauer-Kraut* of the Germans. This, as you know, is made from the leaves of cabbages, gathered generally in autumn, and from which the stem and mid-rib are removed. They are cut up into thin slices, and are placed in a tub or vat, alternately with layers of salt, until the vessel is full. It is then subjected to pressure and allowed to stand for 5 or 6 weeks (according to the temperature); the lactic fermentation is thus set up and the mass becomes sour. It is cooked by stewing it in its own liquor with bacon, pork, or other fat meat; and certain condiments, as dill or carraway, are added to improve its flavour. In Prussia, and in many parts of Germany, there is a similar preparation of fermented beans; and in Holland and the South of Europe, cucumbers are fermented. We also have our pickled vegetables in which acetic acid takes the place of lactic acid. All these preparations are no doubt aids to digestion, especially when the fibre of meat is tough, and contains tendons or hardened cellular tissue. This is especially so with salted meat, and, therefore, a little pickle is always a good and palatable addition to cold boiled beef.

Vegetable substances, as *tea*, *coffee*, *maté*, *cocoa*, *&c.*, the infusions of which are used as beverages, are prepared for commerce in nearly the same manner. When taken from the tree, and while in a fresh condition, they are allowed to undergo a moderate kind of fermentation, and they are then dried and roasted. In the case of tea, the roasting operation is performed during the process of drying and curling, by heating the leaves upon wire sieves held over a charcoal fire, but cocoa and coffee are roasted in metallic cylinders, which are kept revolving over a clear fire—coffee being roasted until it is partially charred, and has lost from 14 to 20 per cent. in weight. By this means the aroma or volatile oil, is in each case produced, and there is also an empyreumatic change in the astringent acids, the sugar, the gum, and the starch, whereby extractive matters, varying in amount and quality, according to the degree of heat, are formed. Schrader has examined the subject in respect of coffee, and has ascertained that the following are the proportions of the several constituents in raw and roasted coffee:—

	Raw Coffee.	Roasted Coffee.
Peculiar coffee principle ...	17·58	12·50
Gum and mucilage	3·64	10·42
Fatty matter and resin ...	0·93	2·08
Extractive	0·62	4·80
Woody tissue and cellulose ...	66·66	68·75
Mixture, &c.	10·57	1·45
	100·00	100·00

Infusions of tea and coffee should be made with boiling water, but they should never afterwards be boiled, for the aromic principle is very volatile, and would be thus lost; besides which a decoction of tea or coffee is disagreeably bitter, on account of the solution of the coarse forms of extractive matter. Soft water also extracts these matters,

and, therefore, appears to give a stronger infusion than moderately hard waters, but it is always at a sacrifice of delicate flavour. Excellent tea is made in London with water of 14 or 15 degrees of original hardness, and of about 5 degrees when boiled. This was a subject of investigation by the Government Chemical Commission (Professors Graham, Miller, and Hofmann), who were appointed in 1851 to inquire into the chemical quality of the water supply of London; and they reported, that, in their experiments they found, that tea made from the boiled London water of 5 degrees of hardness, could not generally be distinguished from tea made with water of 2½ degrees only; although a delicate palate would recognise a slightly increased bitterness without any enhancement of flavour in the latter. It would seem, indeed, that moderately hard water makes the best flavoured tea, provided it is allowed to stand upon the tea sufficiently long. In the case of the Greenwich pensioners the tea was made from water of 24 degrees of hardness before boiling, and 18·6 degrees after; but the infusion was maintained for half-an-hour, by surrounding the vessel with a steam case; and thus an excellently flavoured tea was obtained. The Commissioners indeed truly remark, that "where any great loss of strength of tea infusion has been observed in passing from a soft water to a harder, it may be probably referred to the circumstance that the mode of infusing it has not been properly adapted to the hard water; and then there is doubtless some waste of tea." Lake waters have been a good deal extolled on account of their softness, and supposed fitness for making tea, solely because they happen to produce a deep coloured solution, which conveys a false notion of strength, but, in reality, flavour is always sacrificed for the mere look of the thing, there being no increase of physiological or dietetical property. The Chinese, who are very good authorities on this subject, never use either very soft or very hard waters, for their rule is to take the water of a running stream—"best from the hill side, and next from a river." We may conclude, therefore, that water of from four to seven degrees of hardness, after being boiled, is best suited for infusions of tea and coffee; for such water dissolves the aromatic and physiological constituents, without extracting the disagreeable bitter principles. In the case of coffee, in fact, a little acid, as a portion of lemon juice, improves the flavour notwithstanding that it adds to the hardness of the infusion. Experimentally it is found that infusion of tea and coffee are strong enough when the former contains 0·6 per cent. of extracted matter, and the latter 3 per cent., so that a moderate sized cup (5 oz.) should contain about 13 grains of the extract of tea, or 66 grains of coffee. These proportions will be obtained when 263 grains of tea (about 2½ teaspoonfuls), or 2 oz. of freshly roasted coffee are infused in a pint of boiling water; and the amounts of the several constituents dissolved are about as follows:—

	Tea. Grs.	Coffee. Grs.
Nitrogenous matters	17·2	44·0
Fatty matter	...	3·0
Gum, sugar, and extractive ...	31·7	103·2
Mineral matters	9·1	22·8
Total extracted	58·0	173·0

So that tea yields to a pint of fresh water, about 22 per cent. of its weight, and coffee about 20 per cent. Lehmann found that only 15½ per cent. of tea was dissolved by water; whereas, Sir Humphrey Davy estimated it at 33½ per cent. No doubt the quality of the water, as well as that of the tea affects the results, for distilled water will extract from 40 to 44 per cent. of black tea, and nearly 50 per cent. of green, but for all this, about 22 per cent. is a good average.

Tea is generally measured into the tea-pot by the spoonful, and Dr. Edward Smith has made a curious inquiry into the average weights of a spoonful of different kinds of tea. The results are here shown:—

WEIGHT OF A SPOONFUL OF TEA.

Black Teas.	Grs.	Green Teas.	Grs.
Oolong	39	Hyson	66
Congou (inferior) ...	52	Twankay	70
Flowery Pekoe ...	62	Fine Imperial ...	90
Souchong	70	Scented Caper ...	103
Congou (fine) ...	87	Fine Gunpowder ...	123

From which it would seem that from three to seven teaspoonfuls of black tea, or from two to four of green are required for a pint of infusion of the strength already given.

Cocoa is best made by boiling the mixture for a little while, for it nearly always contains a large proportion of starchy matter, which has been added to dilute the rich fat of the cocoa. Indeed, cocoa contains so much butter or solid fat (from 48 to 54 per cent.), that it is necessary to reduce it with some easily digestible substance, as starch, lentil powder, carageen moss, Iceland moss, sugar, &c.—hence the various preparations of it called *granulated cocoa, soluble cocoa, chocolate, &c.*, the processes for making which I will briefly describe. When the berry is roasted and is cold, it is passed through a machine called a "kibbling-mill," which deprives it of its husk, and of the thin skin which surrounds the kernal or nib. If the nibs thus cleaned are ground in proper mills, they form the variety of cocoa called *flaked cocoa*, but if other preparations are to be made, the nibs are ground between heated rollers or otherwise, until they form a smooth paste, when the diluting substances are mixed with it and are thoroughly incorporated. If *soluble cocoa* is to be made, the diluting material is sugar with some kind of arrowroot, as tous les mois, maranta, curcuma, &c. If *chocolate* is required, the diluting material is sugar only, with some flavouring agent as Vanilla, and if fancy preparations as *carrageen moss cocoa, Iceland moss cocoa, lentil cocoa, &c.*, are required, then these are incorporated. *Granulated cocoa* is a preparation of cocoa, with sugar and starch, so ground as to form a coarse powder, in which the particles of broken cocoa are covered with a layer of sugar and starch. It is obvious that whenever the mixture consists of starch or other farinaceous substance, the solution of the cocoa preparation must be boiled; but when sugar has been used, as in chocolate, which is the most ancient preparation of it, the combination is such as to require no culinary treatment; or, at most, the action of boiling water or boiling milk.

It is remarkable that, although cocoa is much less used than either tea or coffee, yet it was known in Europe a century before either of the others. As early, indeed, as 1520 it was brought from Mexico by Columbus, who found it the common beverage of the people; and when Cortes was entertained at the Court of the Aztec Emperor, Montezuma, he was treated to a sweet preparation of cocoa, called *chocollatl*, flavoured with vanilla and other aromatic spices, and served to him in a golden vessel. The Spaniards thus acquired a knowledge of the berry and of its chief preparation, which they kept secret for many years, selling it very profitably as chocollat to the wealthy and luxurious classes of Europe. It was, however, an expensive preparation, and did not come into general use until long after the public coffee-houses of London were established. The earliest notice of it, according to Hewitt, is in Needham's *Mercurius Politicus* for June, 1659, wherein it is stated that "chocolate, an excellent West India drink, is sold in Queen's-head-alley, in Bishopsgate-street, by a Frenchman, who did formerly sell it in Gracechurch-street, and Clements Church-yard, being the first man who did sell it in England;" and its virtues are highly extolled. This was about five years after the London coffee-houses had been established; for the first of them is said to have been opened in 1650 by a Levantine named Pascal Rosee, in St. Michael's-alley, Cornhill; and a year after they were opened in Paris, and in Holland. In 1660 they were so much frequented, and coffee was so largely drank, that they were made a source of revenue, a tax of 4d. a gallon being levied on all the coffee drank in

them; and three years later they were regularly licensed at the Quarter Sessions, like common taverns. In 1668, when Ray, the distinguished naturalist, published his History of Plants, he tells us they were as numerous in London as at Cairo; and at last they became so great a nuisance, on account of their political associations, that in 1675 Charles the Second endeavoured to suppress them by proclamation, calling them seminaries of sedition; but the keepers of them were sufficiently powerful to make him revoke the prohibition. The history of these houses would form a curious chapter in politics and literature, for they are associated with the earliest development of free political discussion, and with the greatest names in English literature. Among the oldest of them is the "Grecian," where Shakespeare and Rare Ben were frequent visitors; and hardly less ancient is "Wills," where Dryden held forth with pedantic vanity, and where the foundation was laid for that critical acumen which soon became a distinguishing feature in English literature. In the city, too, there was Garraway's, where not only was tea first sold, but where, in Defoe's time, "foreign banguiers," and even ministers resorted to drink it. "Robins" and "Jonathans," and the "Cocoa-nut Tree," in St. James-street, were also famous, and had their distinguished followers.

(To be continued).

THE ORATION DELIVERED AT THE NINETY-FIFTH ANNIVERSARY OF THE MEDICAL SOCIETY OF LONDON.

By W. F. TEEVAN, B.A., F.R.C.S.,

SURGEON TO THE WEST LONDON HOSPITAL, SURGEON TO ST. PETER'S HOSPITAL, LATE LECTURER ON ANATOMY AT WESTMINSTER HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—We have met together this evening to celebrate the ninety-fifth anniversary of the Medical Society of London.

What greater compliment can I pay the Society than the bare enumeration of its years? That fact alone trumpets forth more eloquently than any words of mine can, its vital strength, its genuine worth, its great past, its useful present, and its promising future.

Surely each one of us will say to night as we drink the great toast of the evening,

"Floreat in æternum."

It is my pleasing duty to-day to congratulate you all on the present state of the Society. Under the auspices of our worthy and respected President, whose kindly disposition and urbanity of manners, carry us all captive, the society has received an accession to its numbers, so great as to be almost unparalleled in its annals; such a fact alone shows how very much we have run into a debt of gratitude with him.

The financial condition of our Society is most healthy, and such as to be regarded with the liveliest satisfaction by all its friends.

During the past year we have had an array of papers such as will bear favourable comparison with any year, and the session has been terminated by a series of Lettsomian lectures so admirable as to be beyond all praise.

The regret which we all feel this evening in parting with our President is greatly lessened by the knowledge that his seat will be filled by no unworthy successor, but by a gentleman whose scientific reputation is European.

Under the guidance of our new President fresh fields will be opened up in which we may exercise our usefulness, and I trust his great powers will be exerted in occasionally recommending to the Society committees to investigate, under his captaincy, subjects of great public and professional interest; and that he will thus be afforded opportunities for the employment of his great mental powers, scientific attainments, deep research, and suggestive penetration.

And now, gentlemen, let me personally thank you for the very great honour you have conferred upon me. I feel that the position of your orator is a difficult one. The society in its wisdom and generosity, leaves him perfectly unfettered as to the choice of his subject; and hence it is that his post is one of very serious responsibility.

Now, I cannot but help thinking that one of our national failings for some years past has been a disinclination on the part of men placed in public offices to accept their responsibilities, to do their duty to the best of their ability, and then to shrink from no results. Be it my lot this evening to do what I, in my humble judgment, consider best to be done, and to leave the rest in other hands. Although on an occasion like this it is desirable that the discourse of your orator should be ornamental, yet I think I am not mistaken when I say that it is still more to be wished for that it should be useful.

In our profession there are few, but very few occasions, on which we are able to depart from the routine of our daily work, and take a glance around us to see how we are getting on. Hence it is that I look upon these opportunities as very valuable; for we, to-day, pause in our career, make our annual stock-taking, and see the state of the debit, and credit sides of our account; and, as we are all disposed to be in the best of humours on these festive opportunities, we are better able to take council together. I know that we all here have but one object in view—the welfare of our profession—hence, I feel assured that no remark of mine will be misinterpreted, but, on the contrary, be received, as it is given, in a spirit of kindly charity and friendly brotherhood.

Gentlemen, I will now proceed to take a hasty glimpse of our profession, and I think my time will be best employed not in complimenting ourselves on what has already been accomplished, but in ascertaining what yet remains to be done, and inquiring into the best means for fulfilling the ends in view.

I would first cast my eyes on that all important subject, medical education. It is to us the irrepressible object, and it is constantly starting up to view when least expected. Within the last few weeks the point has been very forcibly brought before us through the masterly, philosophical, and very practical address of Mr. Simon to the Medical Teachers' Association. There can be little doubt that his views are thoroughly shared in by all the younger and thinking portion of our community. Having for ten years been brought into intimate relationship with medical students in my capacity as teacher, I think I am able to gauge the present deficiencies of medical education. You will, perhaps, therefore, be anxious to know what your orator thinks of Mr. Simon's suggestions. He has only to say, that he fully endorses all that gentleman has recommended. I must not here forget to state that a previous orator of this Society has forestalled Mr. Simon's opinions. In the oration given four years ago by Dr. Thudichum occur these very pregnant words—"The greatest deformity of our educational system, compulsory attendance upon lectures and courses of a practical kind, will have to be abolished. The severity of examinations, on the other hand, will have to be increased. The law will say to the student—You may acquire your knowledge where and howsoever you please; but we demand of you full and sufficient proof of your possessing the knowledge which is deemed requisite for the practice of the medical profession. To the licensing authorities the law will say—"It is your duty to satisfy yourself by written and oral examinations, by every practical test that can be applied in the dead-house, the sick-ward, or the laboratory, of the competency of the candidate who comes before you to obtain your license, and in no case are you authorized to assume the competency of a man in any branch of learning, simply because he is certified to have sat so many hours on the college benches, or to have walked up and down the wards of a hospital on so many days." Much and more might I add. Suffice it for me to say, that Dr. Thudichum has already given to the world the pith and essence of Mr. Simon's address.

In years to come, when this reformation, so devoutly to be wished for, has taken place, with what pleasure and pride will not our successors in this Society look back to

the time when the seeds of such good fruit were sown by this Association. May I, like Apollo, water that which has already been planted. I cannot here forbear to pay a passing tribute to those with whom I have spent some of my happiest time, and state how easy and agreeable has been my task of teaching medical students. Their conduct as a body is most exemplary, and when we consider the very many temptations by which they are on all sides surrounded, we cannot fail to be struck with the extreme variety of any instance of reprehensible conduct amongst them ; and if the good relationship which ought always to exist between the teacher and the students is in any way impaired, it will generally be found that it is due rather to some want of taste, judgment, or discretion on the part of the teacher rather than to any mulish or bearlike proclivities on the part of the student.

Can any one say that medical education, as now conducted, needs no reform? The very existence of an individual capable of making such an affirmation would be a curiosity. Then, again, do all our great examining bodies do ample justice to the British public? Do they supply them with an article which is always as it ought to be? or is it not a fact that through the inefficiency of the examination of some of our institutions, incompetent medical men are occasionally let loose on an unoffending people.

In order clearly to get at the root of the present imperfections in medical education, we must, *firstly*, look at the examining boards, who are virtually the Government Inspectors ; *secondly*, at the great manufactories of medical men ; and, *lastly*, let us inspect the raw article—the medical student—and see if there is anything wanting there.

We have in this country a *number* of examining boards so enormous as to be, I believe, unparalleled in any country. In what way does that injure our profession, and tend to lower the standard of the final test. In this way the evil acts—it is a notorious axiom in warfare that it is useless to besiege a town unless it can be entirely surrounded, and the enemy's communications cut off, for so long as the enemy can enter or depart at pleasure, he can in no way be forced to surrender, and the prospect of his capture is indefinite. We saw a remarkable instance of this in the prolongation and unsatisfactory termination of the Crimean campaign. So often as the allies attacked the town and inflicted any damage on the enemy, so often was he able to send into the town fresh forces and thus recruit himself, inasmuch as his communications were not cut off, and thus it was that after all the allies only took part of Sebastopol, and afforded Prince Gortschakoff an opportunity of performing one of the most skilful feats of modern times—that of withdrawing his entire army intact from under the very noses of the allies without their knowledge or consent.

The entire body of medical students may be likened to an army in a town imperfectly besieged. They want to escape from their captivity as students, and emerge on to the golden plains of practice, and the examining boards do not intend to let them pass the lines until they have afforded certain evidence that they can be trusted. Now, what is the use of a splendid brigade, commanded by able officers, attacking one part of a besieged town if another part is assaulted by an inferior force with indifferent officers, *which* allows the enemy to escape safe and sound with his booty. So it is in our profession. What is the good of the standard of examination being kept very high at one institution, when the rejected student can, in a few days later, pass the examination of another board.

So long as students can slip through as they do now, so long will anything like perfection be unattainable. It is a notorious fact, and one which is occurring every day, that a student will go up to an examination, get plucked, and in a few days afterwards present himself to his astonished fellow-students with the diploma of another institution in his pocket. This fact alone would show what very grave offence lies at the doors of some of our examining bodies. Thus, therefore, the multiplicity of boards, each being endowed with the power of granting a license to practice, is in itself a very serious injury to our profession.

The competition between various boards acts injuriously in many ways, but chiefly by lowering the general standard of the final test. Examiners are unfortunately only too well able to recognise the inexorable logic, that a high standard of examination means so much less for their breeches-pockets. How can this evil be remedied? I see but two ways. Either by the State recognising the diploma granted by one examining body only, and thus forcing all to pass it, or else, by all the examining bodies agreeing to require a very high standard of proficiency, and in order that the same might really be carried out, it would be requisite for the Examiners of the College of Surgeons of London to go to Edinburgh to examine the candidates for admission to the College at that place, and for the Edinburgh examiners to come to town. In this way a fair examination might be established, and the very obvious objection to my proposition avoided, and thus a great step would be gained on the present order of things. I would here devote a few words to that particular body with which we, as Englishmen, have chiefly to do. I mean the College of Surgeons of England. That institution, placed by the Government of this country in a most responsible position, and having the twofold duty to perform of providing the public with fit and competent practitioners, and at the same time cherishing and elevating the status and scientific reputation of its alumni, has not acted up to its high mission, and hence has drawn down on its head severe, but merited castigation. I have, on an occasion like this, no wish to enter on to the past of that institution, for did I do so, I am sorry to say I could find but little to recommend to your praise. Therefore, let the curtain drop on the past, and, as the Council seems in some degree awakening to a better state of things, I would, as a member of the English public, ask it these questions—What right have you to let loose on me a man who is utterly incapable and incompetent? What right have you to cause my death to take place at the hands of such man, either by an act of omission or commission on his part? I am quite sure the Council would reply that it had no such right. I would then ask it—How, then, is it that you do allow incompetent men to pass your examinations? I will not put it to the pain of answering this question, but I will answer it myself. The reason why incompetent men are able to pass your examinations is, because your examinations are inefficient, and are no tests at all, or at least very bad ones, as to a man's efficiency. The Council may, perhaps, deny that its examinations are as I have represented them to be. Let them digest a few facts which I will now relate, and of which I have personal knowledge.

A gentleman, whose entire knowledge of anatomy, as obtained by dissection, amounted to one week's rough dissecting on the lower limb, presented himself at the anatomical examination at the College of Surgeons, passed it, and in due time became a member. Some of you would, perhaps, be anxious to know how he accomplished it. Six months before the examination he placed himself in the hands of a grinder, and the three entire days before the examination he passed in the dissecting-room, going from table to table with an able student, who demonstrated to him the various parts exposed. Here, then, gentlemen, was a case of a student utterly deficient allowed, by the carelessness and inefficiency of the examination, to pass the College and obtain a license to practice. I maintain that, had the examination been conducted as it ought to have been, this gentleman could never have passed. As it was, he came down to the dissecting-room after he had got through his examination, laughing in his sleeve at the examination, and maintaining that he had worked a great deal too hard for it, and persisting that three months' preparation, instead of the six he had given, would have been amply sufficient.

Another instance. A gentleman who had passed the College of Surgeons became a candidate for a certain ap-

pointment. He was called upon to give some evidence of his anatomical and surgical skill, and was requested to tie the common carotid artery on the dead subject. Instead of the artery he tied the external jugular vein. He was then desired to tie the common femoral artery, and instead of the artery he tied the saphena vein. It was thought well to give him some further chance, but he still persisted in tying the veins instead of the arteries.

Some more facts. Six gentlemen, who had all obtained the diploma of the College of Surgeons, were candidates for certain appointments, and were requested to operate on the dead subject. Each applicant had given to him a large artery to tie. After each gentleman had performed his operation, the examiner inspected the parts and then reported, that if each of these gentlemen had been operating on the living instead of the dead subject, he would in each instance have killed his patient.

So much, gentlemen, for the efficiency of the present examinations at the College of Surgeons. But how can we expect efficient examinations conducted by inefficient examiners? With the exception of surgery, I am not aware that the examiners, as a rule, possess the requisite qualifications on their part to ensure efficiency. How can a man who has not practised anatomy for, perhaps, nearly half a century be deemed fit to examine? He is manifestly unfit.

Then, again, we should be glad to know what evidence there is that the present examiners know anything about microscopical anatomy. As to examinations in surgery—a man who learnt his surgery half a century ago is very likely to examine according to what surgery was in his days, and not what it is in ours. Hence it is, that there has always been an inclination on the part of the examiners of the College of Surgeons to give catch questions, which means something I would not like to say. However, I believe better things are in store. The Fellows of the College are now looking after their own affairs, and I trust that before long the Council will be purged of its obstructives, for I know there are men amongst them of enlightened views, and anxious to bring the College in harmony with the requirements of the day. The first step the Fellows must insist on is the publication of the minutes. If the Fellows, as a body, undertake to return no one who is not pledged to obtain the publication of the minutes, we shall soon get them, and thus know who is for us and who is against us.

The College of Surgeons seems never to have realised the fact, that it is for it to fix what the standard of the final test must be. I state most emphatically, that the body of the students will educate themselves up to the standard required by the College, but no further will they go. Why should they? When the mature heads of the Council have deemed that what they ask of a man is amply sufficient to make him a good practitioner, why should the student or teacher carp at the examiner and demand a more strict examination. Would it not be unseemly for him to do so? What would the venerable gentlemen say, if their private patients put their prescriptions aside and demanded stronger doses? Why they would immediately exclaim—"Do you think you know better than we do."

I would, finally, be glad to know how it is that the College of Surgeons, who are virtually Government Inspectors for the department of Medicine, differ so materially and sadly from all the other Government Inspectors. In all other departments we find that when any article, whether it be a soldier, sailor, iron, or wood, which is required for the public service, the Inspectors of the Department of the article required, meet and agree upon the quality the article about to be supplied shall be of. Having done this, they advertise minutely the requirements which the article must fulfil before they will pass it, and then they invite tenders for the supply of the same. They do not care whether the article is made in Kent or Surrey, by Brown or by Jones, all they demand is, does the article evince the quality they require.

No one can doubt but that in time the Inspectors of Medicine will do the same as the Government Inspectors for the other departments do with the best results.

The examiners to the Naval and Military Boards have evinced, to their honour be it said, a keen sense of the responsibility of their position, and hence they consider that because a student has passed the College of Surgeons, that he is not therefore necessarily fit to practise on those costly articles—British sailors and soldiers—and they consequently do all in their power to repair the shortcomings of the College of Surgeons.

And now, gentlemen, having made these few remarks in no unfriendly spirit towards the Council of the College of Surgeons, for many of whom I have the highest respect, I will proceed to take a glance at the teaching in this metropolis, and see if there is anything which admits of improvement.

I much regret the recent action of the Medical Teachers' Association in reference to attendance on lectures. Such a procedure argues a want of knowledge of human nature. It is the old error repeated over again for the thousandth time, for I hold it is just as unphilosophical and unwise to attempt to make students studious by forced attendance on lectures, as it is to attempt to make young men religious by forcing them to attend religious observances. What is it that makes young men so little in love with religious services? Is it not that ecclesiastics have thoroughly nauseated them with a dry formularism during their school and college days? That Apostle was indeed a philosopher who said—

"The letter killeth, but the spirit giveth life."

By making attendance on lectures compulsory, the grave risk is run of rendering students disgusted with that which ought to be a labour of love.

I maintain that the only and proper way in which students can be influenced for good, is to infuse into them a spirit of love for their profession—once get a student to love his profession, and all will go well. He will require no looking up or compulsory attendance on lectures, and if, on the contrary, he cares not for his studies, no amount of forced attendance will make him love them more, but will cause him to still more detest the burden that galls his back.

Some people do not seem to realise the fact that Medical students are not mere school boys, but reasoning, thinking, intelligent young men, who are quite capable of appreciating the fact, that as they make their beds, so they must lie on them, and my remark applies with especial force to English students, for they above all others in the world, have an eye to the main chance. I should be glad to know why a student should be compelled to attend the lecture of a teacher who cannot teach him anything. It is perhaps rather a startling assertion to make, but I maintain that no lecturer on anatomy can, to any purpose, teach more than twenty students at the same time. I hold that all lectures which are not demonstrative are useless, and hence it is that every lecturer ought to assure himself that each of his class can not only hear what he says, but also see what he demonstrates. In the larger schools the majority of the students get up their knowledge of anatomy without any assistance from the lectures on anatomy. How can it be otherwise? Let anybody sit in the fourth or fifth benches, and then say how much he can see of the dissected parts. Practically nothing. But you will perhaps exclaim, "see how the operating theatre is crowded on operating days." So it is. But what, I ask, do the majority of the spectators see of the operation of lithotomy? Why, they see everything except the operation. Under the present regulations the student is burdened with a most cumbersome and useless machinery, which forces him to select one school, and to take it for better or for worse. Thus he loses his liberty of action, the better promptings of his heart are stifled, and he leaves London, not feeling that he must for ever remain a student if he would do his duty properly, but thanking himself for having at last escaped from the drudgery of his school.

It must be confessed that the quality of teaching not

only varies in different schools, but in different departments of the same school, so that one school has a first-rate teacher of clinical medicine perhaps, and an indifferent teacher of clinical surgery. That such is the case we have abundant proof. Go to any school in this metropolis, and you will find the clinique of one teacher crowded, whilst that of another is deserted. In fact, students are constantly to be heard saying, "What is the use of my going round with Mr. So and So. I cannot learn anything from him." Some teachers are extremely communicative, and encourage students to ask questions, and to take an interest in the case; others are reticent and cut short any attempt on part of the young student to obtain information. Then, again, clinical teaching must be regarded as defective at many of the larger schools. There are some teachers to whom I would say, "How many students have you in your class?" and the answer would be "50 or 100." "And pray, how many students can be taught at once and the sametime, at the bedside?" "Not more than a dozen at the outside." "And what provision is made for the other students?" "None at all."

At one time I was strongly opposed to the smaller schools of medicine in this metropolis, and considered it would be well if they were abolished, but having had experience in teaching in a large and a small school, I must give my preference, in the present state of things, to the smaller school, for in it the student is brought, on his very entry, into close connection and daily intercourse with his teachers. In large schools many of the students do not get five minutes conversation with a single teacher during an entire session, whereas at the smaller ones the teachers are conversant with the habits, wants, and feelings of every student. With medical students a little kindness goes a great way, and I have always observed when a thoroughly efficient teacher takes a personal interest in the members of his class, the number of absentees is reduced to zero.

One evil that is creeping into clinical teaching, and impairing its efficiency is, that many of our general physicians and surgeons are specialists, and hence they convey no weight or no authority with students, beyond their particular selections. Students are beginning to exercise the same freedom of choice as regards their presence or infrequency of attendance on the lectures of a teacher's course, as they do when they fix upon who is to attend them for their occasional complaints. If a student has the misfortune to have a stricture, he goes to a surgeon whom he calls "a stricture man," when his chest is bad he goes to "a chest man," when his kidneys are out of order he goes to "a kidney man," if he squints he goes to an "eye doctor," if he sneezes too much he goes to a "nose man," if his throat tickles him he goes to a "throat man," and if, when he is coming to town by rail, he happens to be unlucky, and gets into a collision, he goes next morning to a "railway man." Now, all this is only right and proper, but the student should, in all fairness, be enabled to make the same selection as regards his teaching as he does regarding his doctor; but as long as the present regulations obtain he cannot do this, inasmuch as the teachers he would select are scattered over the metropolis.

When our present wretched anti-English system of rules and ordinances, monopoly and protection, is abolished, we shall find that students will go to that man who can teach them best, a thing they are now practically unable to do.

I maintain that the privilege of selecting the man from whom he can most profit, is the birthright of every English student, and of this right he has been deprived by the present *strait*-laced system.

When that day comes, which is I trust not far off, when the student will be as free as such as he is as a man, we shall find only thoroughly efficient teachers in this metropolis, because the incompetent ones will die of pure inanition—their benches will be deserted, and their supplies cut off. In this way the student will, of his own unaided efforts, be able to set all things to rights. Once strip him of all the useless machinery under which he now groans, and you will at once see what a splendid fellow he is, and what good running he will make in the race of life. At present the medical student is like a high mettled racer with a bad rider on his back, who is worrying him and fretting him, and won't allow him to have his head. I would say to the rider, "The best thing you can do is to get off his back, or otherwise you may goad him into shaking you off. You have given abundant proof that you do not understand him, and that you are unable to ride him."

Another glaring defect in the present regulations is the period fixed for studentship. If four years be a right and proper time for some, it is evidently much too long for a few, and much too short for others. To fix a stated time for the duration of a student's education, is about as rational a proceeding as if the College of Surgeons were to issue an edict ordering all the medical students of London to have their breeches cut the same length. The Council seem to imagine that all men are of equal mental and physical power, and live under the same conditions, whereas it is a notorious fact that the Deity has made no two men alike. No one can, therefore, say what time is requisite to make a man fit to exercise his profession, and hence the absurdity of gauging all men with the same measure. I, finally, strenuously contend that examinations ought to be made the test, and the only test, of a man's proficiency. What does it matter when, where, or how, a student obtains his information, provided he does obtain it, and if he has not got it what do all attendances on lectures profit him? Let us convert students into living realities, and not reduce them to museum preparations as they too often are now.

Let the University of London, the champion and vanguard of all improvements, do for medicine what it has done for arts. It has allowed the candidate for the Bachelor of Arts degree to throw of his shackles. May it permit the candidate for medical degrees to do the same.

And now, gentlemen, having taken this hasty and imperfect sketch of examiners, teachers, and students, let me look for a few minutes at the patients—Can their condition, as recipients of relief, be improved? Can we do more for them than we are now doing? Is there anything which we ought to grant them which they do not now enjoy? I answer, there is. I would draw attention to two glaring defects in our hospital administration. *Firstly*, the system of admission by letter; and, *secondly*, the enormous loss of time which the out-patient incurs in obtaining advice and medicine. With a few noble exceptions the admission into our hospitals is, for cases of disease, procurable by letters of recommendation only—a system which, I believe, obtains in no Christian country except our own, and the hardships of which are known only to the poor wretch who has to go about from place to place begging for a letter. I maintain that any other, or more recommendations than poverty and disease, are immoral and the system, as at present existing, will, in subsequent ages be looked back upon with disgust. When subscribers to charitable institutions fetter their charity with such absurd conditions that the poor sufferers are obliged to go about limping for letters, I hold that their charity avails them not. What a mockery of charity, to force a destitute creature to expense or pain in order to procure the badge of his slavery!

The evil acts in this way. Supposing, for instance, the wife of a labouring man with a large family is ill and wants to get into a hospital; she is obliged to get a letter, and for that purpose she must either pay some one to go and look for a letter, or go herself and pay some one to stop at home to look after her children.

The result of all this is that subscribers have taxed heavily those they relieve, both in time and money. Then again the system of admission by letter increases the amount of disease and consequent mortality amongst the poor.

I need only mention one instance to condemn the system. A poor woman brought her child, which was suffering from purulent ophthalmia, to a hospital. The child's eyes were

perfect. Three weeks afterwards the woman again brought the child. Its eyes were destroyed. It was a rule of the hospital that no patient could be seen a second time without a letter. There was an exception, however, in favour of diseases of the eye. But what did the poor woman know of exceptions—she could not even read. All she knew was that letters were required and it took her three weeks to get a letter, during which period the child's eyes were spoilt. I am sure the majority of subscribers to a hospital are both enlightened and humane, and the abolition of admission by letter is one of those things which has only to be asked for to be granted.

The second evil is that at present patients are kept a great length of time which they cannot afford to lose, waiting for advice and medicine. The majority of the out-patients' rooms are crowded from 12 P.M. to 4 or 5 P.M. and each patient is kept on an average at least two hours before he can get both advice and medicine.

The result is that a working man cannot make use of a hospital, for no employer will permit him to absent himself for the requisite period without a deduction from his wages. Hence a working man goes on till he drops, and so, largely increases the bills of mortality. If instead of a brace or so of dispensers at hospitals, there were a dozen put on the above evil might be considerably lessened, and the usefulness of our hospitals proportionably increased.

I would be glad to know where the working man with a pound a-week to live on, and a wife and children to keep, is to go when some slight ailment attacks him.

He cannot go to a hospital, because the time fixed for seeing out-patients is during his work hours, when, as I have said, the employer will either not let him go or else make a deduction from his wages. He cannot afford to pay a doctor, and so this honest fellow—one of those who has contributed to make this country what it is, is left totally unprovided for in case of slight illness.

If working men could go after their work was done to a hospital, when suffering from any light complaint, I maintain that it would be an enormous boon to them, that it would enrich the nation and greatly lessen our national mortality.

Why should there not be appointed at every hospital an additional assistant-physician and assistant-surgeon to see the patients in the evening after they had done their work?

Much and more there is, gentlemen, which I would have wished to touch on, but time will not permit, and I have therefore contented myself with touching, feebly and imperfectly perhaps, but still in earnestness, those evils which seem to me to require immediate attention and remedy.

And now, gentlemen, in conclusion, let me congratulate you all as to the way in which Man is getting on in this world. From whatever point we regard him, wherever we may look, we see on all sides signs of gigantic progress. So great is it, so swift is it, that we, passengers, are almost unable to discern the objects brought into view. The future historian who shall calmly and dispassionately sit down to write the record of our age, will alone be able to measure the immensity of its progress.

All the world over, far above the din and turmoil of life, we hear but one sound—that happiest of all sounds—man breaking his chains; and this poor wretch, this worm of the earth, as he has been called, which has been bled, beggared and oppressed for countless ages, is now proclaiming in no faltering or uncertain tone, his great and indefeasible right to his magnificent heritage and splendid destiny. What is all history but the narration of the struggle of man against self-constituted and self-imposed authority? At last he has struck off his shackles, he breathes freely, and, with head erect, he may now indeed put his hand on his breast, and, with truth, exclaim:—

"Homo sum."

Hospital Report.

MATER MISERICORDIÆ HOSPITAL.

ACUTE PLEURITIS, WITH EFFUSION.

Under the care of Dr. HAYDEN.

ANNE GAFNEY, aged 26 years, a servant, admitted into Hospital February 11, 1868. She stated that on Friday, January 31, whilst engaged in baling out water, which had found entrance through the roof of her master's house, stript during the rain-storm of that night, she caught cold, and was attacked with pain in the left side on the following day. She gave little attention to this pain, endeavouring to perform her duties as house-servant for several days, during which she received no medical treatment of any kind.

When admitted she was pale and weak, respiration quick and embarrassed; pulse rapid and feeble. The left side of the chest was dull from base to clavicle, *but moved freely in respiration;* to the same extent vocal fremitus was abolished, and respiratory sound was absent, except along the spine and beneath the clavicle, in the former of which situations was heard tubular breathing, and in the latter a faint vesicular murmur. Over a space of about two inches, measured from the clavicle downwards, a squeaking vocal sound (œgophony) was heard when the patient spoke. Measurement of chest showed an increase of half an inch in the girth of the left side, as compared with the right; heart displaced to right of mesial line, and *heard* pulsating under right costal cartilages; decubitus dorsal, or diagonal. Directions were given that the left side of the chest should be painted daily with the tincture of iodine, and that the patient should have the following diuretic mixture, in doses of two tablespoonful every second hour, viz., infus. juniper ℥vii., spirit. ether nitros, spirits juniper, aa. ℥ss. Small quantities of whiskey, and light nutritious diet were to be given repeatedly, according to necessity.

February 18.—Over a space of about one inch below the left clavicle percussion-resonance is normal, and here respiratory murmur is heard; to an equal extent lower down there is comparative dulness, and here œgophony is audible. To have gr. iii ss. iodid. potass. in ℥i. aquæ camphoræ thrice daily; to continue painting with iodine; to be restricted in the use of liquids, and to have a sedative nightly, consisting of tinct. of hops and tinct. of hyoscyamus, of each ℥ss. in an ounce of water.

March 6th.—The patient has been out of bed for the last few days; she has recovered strength and colour; can now lie upon either side; dullness has all but entirely cleared up in front, but is still partial posteriorly; the heart has returned to its normal situation, where it is felt pulsating.

Dr. Hayden made this case the subject of a short clinical lecture, and after detailing the diagnostic symptoms and signs by which serous effusion into the pleura may be distinguished from pneumonic and tubercular solidification, cancer, inflammatory thickening of the pleura, &c., he directed the attention of the class to the specific value of the evidence furnished by the free movement of the affected side of the chest, mentioned in the record of the case, in establishing the differential diagnosis of acute pleuritic effusion upon a previously healthy lung, from the diseases above mentioned. He also stated that in cases of pleural effusion on the left side, causing dislocation of the heart to the right, the cardiac impulse is, according to his experience, frequently lost; and explained how this might be the consequence of the anatomical disposition of the left pleura with reference to the apex of the heart; in the state of health the impulse of the heart is felt in the left sub-mammary region, through the pericardiac and costal pleuræ; but when the left pleural cavity is distended with serous, or other liquid effusion, the greater portion of the heart, including its apex, being surrounded by a liquid medium, the apex beat is not communicated to the chest

wall. Hence, the precise situation of the heart can be determined, as in this case, only by the point of maximum intensity of its sounds. The impulse is, however, occasionally felt, as in a case lately observed, in which the heart pulsated below the right nipple. In such cases it would probably be found that, owing to some cause, such as unequal pressure on, or yielding of the mediastinum, the apex of the heart is pushed towards the right side to a greater extent than the remainder of the organ. Dr. Hayden also reminded the class that having watched the progress of the case from day to day, they were enabled to observe the gradual return of the heart to its natural situation, and, concurrently with this, the subsidence of the level of percussion, dullness on the left side of the chest; finally, he pointed out the efficacy of iodide of potassium, given in moderate doses, in such cases.

REPORT TO THE REGISTRAR-GENERAL ON THE METROPOLITAN WATER SUPPLY.

By Dr. E. FRANKLAND, F.R.S.

ANALYSIS OF THE METROPOLITAN WATERS FOR MARCH, 1868.

1 Companies.	2 Date and Place of Collection.	3 Temperature in centigrade degrees.	4 Total solid impurity in 100,000 parts.	5 Organic Carbon.	6 Organic Nitrogen.	7 Nitrogen as Nitrates and Nitrites.	8 Ammonia.	9 Total Combined Nitrogen.	10 Previous Sewage Contamination (Estimated.)	11 Total Hardness.

Worthing ...	NOVEMBER. Worthing.		36·7	·162	·000	·426	·000	·426	3940	23·8

For the purpose of comparison, I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by the waters supplied to the towns of Lancaster, Manchester, Leicester, Preston, and Worthing, when submitted to the same analytical processes. The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 4th March at the Horse Guards cab-rank had a temperature of 8·3°C.; 100,000 lbs. of it contained 29 lbs. of solid impurity; the organic matter constituting a portion of this impurity contained ·187 lb. of carbon and ·029 lb. nitrogen. This solid impurity also contained ·262 lb. of nitrogen in the form of nitrates and nitrites, besides ·003 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·293 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 2320 lbs. of average filtered London sewage.

By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the Company, this sewage contamination had been converted into innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 18·5 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The effects of the great January flood in the Thames have now nearly disappeared. Nevertheless, the water delivered by the Lambeth Company on the 4th inst. was nearly as muddy as the samples collected in January and February. The waters delivered by the Chelsea and Southwark Companies were likewise turbid, whilst the West Middlesex and Grand Junction Companies, who also draw their supplies from the Thames, delivered water which had been efficiently filtered, and was, therefore, perfectly transparent.

The water taken from the river Lea, and supplied by the New River and East London Companies, was also quite transparent. The amount of organic nitrogen in the turbid waters is considerably higher than in the transparent samples. It is therefore highly probable that solid particles of unoxidized sewage enter into the composition of the suspended matter in the turbid samples.

The peculiarities presented by the Kent Company's water, delivered at the Deptford Railway Station, and noticed last month, are exhibited by the sample collected on the 2nd inst., in a still higher degree. The water was turbid from floating fibrous particles. Its total solid impurity has increased from 59·2 in 100,000 in February, to 70·2 parts in March. Nearly the whole of this increase is due to common salt, which, amounting to the very large proportion of 14·4 parts in 100,000 of water last month, has now increased to 23·7 parts.

REPORT OF AN OPERATION FOR HERNIA CEREBRI: WITH OBSERVATIONS.

BY DR. MED. H. HIRSCHSPRUNG.

Translated, with abridgment, from the *Ugeskrift for Læger*, Nos. 16-19, March and April, 1867.

By W. D. MOORE, M.D.Dub. et Cantab., L.K.Q.C.P.I., M.R.I.A.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 70.)

In proceeding to bring forward some points which naturally present themselves for consideration after the communication of the foregoing case and post-mortem examination, I may be permitted to preface my remarks with a review of the forms of tumours which, proceeding from the interior of the cranium, may show themselves upon the head of the new born child. In treating of these forms of disease we touch upon a very fruitful, but at the same time very dangerous soil,—fruitful, because it suggests a number of questions which require an answer; dangerous, because we still must want in various directions firm resting points for a thorough investigation of this kind, and for want of explanation one is easily lost in speculation. It is, therefore, easy to understand that theories play an essential part, and my sketch would not be faithful to the truth, if it did not give a view of the prevailing uncertainty.

Cerebral substance is not necessarily met with in these tumours. Thus in Bednar (*loc. cit.* p. 149) and in Rokitansky (*Lehrb. der patholog. Anat.* 1856, 2, p 408), not to speak of earlier writers (Meckel), who cursorily touch upon the subject, dropsical sacs are mentioned, which are merely diverticula of the membranes of the brain. But even before these statements appeared, the subject was separately treated of by a Belgian author, Spring (*Monographie de la hernie du cerveau etc.* in *Mémoires de l'académie royale de Belgique*, 1854), who is the first who has given a more detailed description of these forms, as the name Meningocele is derived from him. In 1859, Houel in strong terms disputed the existence of meningocele (*Archives générales de médecine*, p. 409); I am not aware whether Spring himself has answered the attack. On the other hand, Gintrac, in 1860 (quoted in the *Journal für Kinderkrankheiten*, 1860, p. 235), undertook the defence of the meningocele or, as he proposes, the hydromeningocele, against Houel, and as Virchow has finally declared himself on the same side, there can no longer be any doubt as to the correctness of admitting such tumours into the nosological system.

It is, however, more difficult to clear up the anatomical side of the question, which we come in contact with in speaking of the mode of origin of the meningocele. Spring looked upon the tumour as an hernial prolapse of the parietal layer of the arachnoid, or as protruding through an accidental opening in the dura mater, or that the latter has been pushed out with it and formed a constituent of the hernial sac. As it appears, Spring still entertains the idea, inherited from the time of Bichat, of the arachnoid as a serous sac, presenting anatomical and pathological relations common to it with the serous cavities in the other regions of the body. But it is well-known that this theory has been overthrown, especially by Luschka's investigations; it has been obliged to yield to the view which looks upon the arachnoid as a single lamina, having an epithelial investment on its outer side, corresponding to that of the dura mater, while its inner surface closely adjoins the pia mater, being separated from it only by the greater and less subarachnoid spaces filled with fluid; indeed Virchow even reduces (l. c. p. 173) the number of the membranes of the brain to two, as he says: "The arachnoid or pia is the membrane which invests the brain, the dura mater that which joins the bone." But even if we could coincide in the earlier view of the anatomy, Spring's explanation of the commencement of the tumours from a circumscribed inflammation in the arachnoid, whereby its boundaries become defined, with consecutive destruction of the adjoining bone, is too improbable to find acceptance. On the other hand, we feel ourselves undeniably appealed to by Virchow's arguments. He admits that there are not yet before us sufficiently accurate investigations, but it appears to him not to be doubtful, that an hygroma developed at an early stage in the dura mater, or a vesicular œdema in the pia mater, may be developed to such a degree, as to present itself externally in the form of a tumour. In support of this opinion he states, that even in adults, atrophy of the lamina vitrea may be produced as the result of partial vesicular œdema of the pia mater, nay, that even protrusion as a lump, of the outer layer of bone, may be so caused.

A weak point common to the theories of Virchow and Spring is this: that they leave unassigned the cause of the meningocele occurring in most cases upon a given part of the head. Spring and Gintrac are on fact agreed on this, that the occiput is the usual seat of the affection. The opening is generally found in the bone itself, more rarely in the sutures or fontanelles. According to Gintrac, the tumour is at birth generally not very large, but it grows by degrees to a considerable size. Most frequently the contained fluid can be pressed back, and the ease of reduction is said to be the best distinctive mark between this affection and Hydrencephalocele, which diagnosis is not always easy. The prospects of the child's life are unfavourable, although not quite so bad as in hernia cerebri. The cases of the last named affection cured by compression, ligature, &c., have, in Gintrac's opinion, undoubtedly been instances of meningocele.

It is clear that the description given will, in cases with which we meet, justify us in assuming the possibility of an encysted tumour; but in turning to the case above reported, we will recollect that what in our patient made the evidence of meningocele rather doubtful, was the fact, that in the neck of the tumour a somewhat irregular solid swelling was felt proceeding from the bone, and as it seemed, from a slight depression in the latter. This would involuntarily direct one's thoughts to a prolapse of the cerebral mass, and only the peculiarity that the projecting apex gave to the touch a feeling of fibrous, nay, almost of bony hardness, shook the conviction of the presence of hernia cerebri.

It may be added that at least one case is found in literature, respecting which it is stated that in the neck of a large congenital sac, a process of the pia mater was met with, which simulated a prolapse of the brain. The case is reported at second-hand in *Medical Facts and Observations*, London, 1797, vol. 7, p. 281. In the right side of the sac, close to the opening in the occipital bone, lay a fungous tumour as large as a walnut. Through the small opening in the bone, the tumour could be traced to its origin from the pia mater on the surface of the brain, while the brain itself was not implicated. But a more accurate acquaintance with this case, has certainly in my mind thrown great doubt upon the explanation. The feeling of a tumour projecting in the neck of the sac, may therefore certainly always be considered as indicating the presence of a cerebral hernia, and it remains only to direct special attention to the peculiar deception of the sense of touch, which might cause a perfectly soft body to present to our feeling a considerable degree of hardness,—a phenomenon which I have subsequently had the opportunity of demonstrating under similar circumstances though in a less degree. In the last mentioned case the child was dead, and the idea hitherto entertained, that the tension produced by sanguineous congestion might be the cause of the illusion, was thereby refuted.

If the tumour contains a prolapse of the cerebral mass, the case is different. Hernia cerebri in fact comprises two ideas, which nevertheless have points of contact, and are by no means clearly defined: Encephalocele and Hydrencephalocele. By the first we understand in general a simple prolapse of the brain, by hydrencephalocele prolapse of an hydrocephalic brain. In both forms fluid may be found in the hernial sac, so that the external occurrence of the latter does not indicate any essential difference.

The pathology of Hydrencephalocele is most developed. Even Morgagni had recognised hydrocephalus as the only cause of hernia cerebri (as well as of spina bifida), and many later writers have supported this opinion, which, however, has not met with general adoption, because of the difficulty of understanding the limitation of the pressure to the points peculiarly liable to the protrusion of the hernia. So long as it was supposed that the hernia cerebri invariably protruded through the sutures and fontanelles, or through defectively ossified parts of the skull, the explanation was always ready, as it was inferred from this circumstance, that these parts had less power of resistance against the intracranial pressure. Experience shows, however, that the opening in most cases is accidental, is excavated in the bone itself, even in the thickest parts, as it is certainly doubtful (Spring) whether the osseous mass is better adapted to resist the certainly weak, but constant pressure, than the tough membranes. It was therefore necessary to seek for other causes of the constant occurrence

of the hernia in the same points, and it is upon the theory of a circumscribed dropsy of the ventricles of the brain that Spring builds his explanation of the origin of hydrencephalocele, which is advocated also by Houel and Virchow. The last named writer expresses himself as follows:—If a general hydrocephalus be met with and the cranium yields, a kind of macrocephalia is developed, but no tumour-like affection. But some parts may be predominatingly affected, as the communication between the several portions is interrupted. It is thus, for example, common to find the cornu posterius in its whole extent or partially obliterated. In this manner an hydrops cysticus cornu posterioris may arise. The several dilated parts of the ventricles with the surrounding cerebral mass may now by increase of growth press outwards, and either hinder the closing of the skull or by pressure gradually produce an opening in the bone, and protrude externally in the form of herniæ. A meningocele is not unusually met with at the same time. Perfectly similar conditions are found in the spinal canal, but these incomparably more frequently, giving rise to spina bifida.

Our experience of partial dropsy of the ventricles reach, however, farther back. Early writers spoke of hydrocephalus dimidiatus, *i.e.*, in one lateral ventricle. The lateral ventricles have been found distended, the third ventricle empty, and *vice versâ*. Dropsy has been seen limited to the pineal gland, and to the cavity of the septum lucidum, &c. The certainty that such partial dropsical processes are met with, affords the foundation of the theory, and if experience shows that the hernia protrudes only at the points of the cranium corresponding to the ventricles of the brain or their prolongations, we have—this must be conceded to Spring—a powerful argument in favour of his pathogenetic theory. Of his scheme I will put forward the following:—

1. Dropsy in the posterior horns of the lateral ventricles: hernial opening between the angulus sup. oss. occipitis and the spina occipitalis near the middle line. Hernia supraoccipitalis.

2. Dropsy in the fourth ventricle: hernial opening beneath the spina occipitalis near the middle line. Hernia infraoccipitalis.

3. Dropsy in the anterior horns of the lateral ventricles: hernial opening at the meeting of the nasal and frontal bones, rarely in the frontal bone itself, near the middle line, still more rarely through the os. unguis. Hernia frontalis seu frontonasalis.

4. Dropsy in the descending cornua: hernial opening in the region of the spheno-maxillary fissure. Hernia orbitalis and spheno-maxillaris.

5. Dropsy in the third ventricle: hernial opening through the body or inner part of the ala major oss. sphenoidei.

If, with the light which the above scheme throws upon the origin of hydrencephalocele, we subject our own case to analysis, we shall find that it is by no means at variance with Spring's theory.

Had we, immediately after the operation, been in doubt whether we had removed a simple hernia cerebri, or whether the latter was complicated with hydrocephalus, this uncertainty must have disappeared on the occurrence soon after of undoubted signs of hydrocephalus. The prolapsed part appeared on dissection to have been the posterior portion of the left cornu posterius, and the hernial opening was found. in accordance with the theory. over the spine of the bone, and in the middle line itself. The left posterior horn formed a direct continuation of the other strongly dilated cavities, but this, of course, by no means excluded the possibility that in its time an obstruction may have existed, which was gradually forced to yield to the constantly-increasing pressure of the augmented quantity of fluid. The occlusion which was met with in the passage from the aqueduct of Sylvius to the fourth ventricle might even, by analogy, justify the inference that a similar occlusion had existed in other points of the cerebral cavity. On the other hand, we cannot, inclined as we might be to believe in the importance of the obliteration for the whole process, disregard the influence which the fluid, by its own weight, might have in protruding the brain through a corresponding point of the skull. nor has Spring shut his eye to this possibility. Of sixty cases which he has collected, forty-one were situated on the occiput, which, in consequence of the usual position of the child's head in the majority of instances, will form the most dependent part, to which the collection of fluid must necessarily gravitate. I, therefore. believe that in the foregoing case we can easily, without taking refuge in the assumption of a then existing closure of the posterior horn, explain the origin of the hernia by the aid of obliteration of the aqueduct of Sylvius, which has placed an obstacle to dilatation in this direction, and also of the concomitant, somewhat increased intra-cerebral tension, but especially of the specific gravity of the fluid, whereby strong pressure was produced inferiorly towards the lowest point of the cranium.

Obliteration of the aqueduct of Sylvius seems moreover not to be a rare phenomenon in these affections. Hyrtl (Haandbog i den topograph Anat., p. 80) says that the serous accumulation in the brain is most frequently confined to the middle and lateral cavities, while the fourth ventricle is rarely dilated, "which suggests the idea of an obliteration of the aqueduct of Sylvius, which may be due to the great narrowness of the canal in connection with the thickening of the serous investment common in all dropsies." We accept the fact, while the explanation must certainly be regarded as highly problematical. I have myself since had an opportunity of seeing the closing of the canal in the same place. On the 10th September, 1866, I made the post-mortem examination, at the Lying-in Institution, of a still-born, mature male infant, who had a large hydrencephalocele hanging down from the occiput. The report forms, so far as the head is concerned, essentially a companion piece to my first case: the hernia protruded through a deep crescentic opening in the upper part of the squama oss. occipitis; it was formed of the posterior part of the left hemisphere, which had broken out through a wide opening into the hernial sac; the tubercula quadrigemina were also here changed to a thin, medullary layer; but the fourth ventricle was uninjured. In this child, too, the head presented.

If we attend to the state of the tubercula quadrigemina in these cases, and remember that the filaments of the optic nerve proceed chiefly from these bodies, we may reasonably put the question, whether vision is possible in such a child. In the concrete case the decision of this point is always difficult, especially when hearing is present, and the child's head may be supposed to turn instinctively towards the sound, which attracts its attention; but absolutely it cannot be denied that the filaments of the optic nerves may have preserved themselves in the medullary layer, which represented the tubercula quadrigemina, as it must be remembered that the optic nerves get filaments also from other parts of the brain—namely, the corpora geniculata and thalamus. Therefore, I ought not decidedly to deny the correctness of the mother's assertion as to the child's power of vision, inclined as I would be from my own observation to ascribe it to an easily comprehensible illusion.

(To be continued.)

WEDNESDAY, APRIL 15, 1868.

THE ST. ANDREWS GRADUATES' GENERAL SESSION.

THE meeting of the St. Andrews Graduates' Association was held last Wednesday evening, according to our announcement, and passed off very successfully, Dr. Richardson, President, occupying the chair.

There is a large increase in the numbers of the Association, upon which we offer our congratulations to the members, though this fact, unfortunately, entailed a great loss of time and materially hindered the progress of other business.

The ballot is a slow process even for the admission of a small number of persons who are well-known to all, and who may probably be elected as a matter of course, how much more so when about 100 persons scattered over the Kingdom are to be submitted to the test! With every wish on the part of the majority to expedite matters it was found quite impracticable to get through the work of the evening, on account of the length of time consumed in balloting for new members ; and it seems to us that the Council of the Association might be trusted with the admission of members. If not, we can only hope that, on a future occasion, some other method may be tried. Why should not a printed list have been circulated beforehand, and the voting carried out by marks placed against the names by the associates present at the meeting? It would perhaps be simpler to admit, as was done last year, all graduates who chose to join, and such liberality would well accord with the primary object of the Association.

The Parliamentary business was not prolonged, as the Secretary had condensed into a very able report an account of all that had been done by the Council, as well as a history of all that had come to his knowledge respecting the movement for securing the rights of graduates. It is now looked upon as a settled thing that the graduates shall be admitted to the franchise, and we may, therefore, trust that the Edinburgh section will cease from a futile opposition, which is only likely to irritate the St. Andrews Graduates into organising a plan to defeat any candidate who may hail from Auld Reekie. Already, as we have mentioned, the friends of some candidates are at work, in the hope of securing hasty promises. It would be good policy to wait awhile; for, as we last week stated, there will be other candidates whose names have not yet been announced, and who will seek for support in the medical interest. No one has yet given a distinct pledge to stand by the principal of justice to all graduates of both the Universities, and without such a pledge we hope no one will obtain the support of the doctors of medicine of either.

Besides the franchise, the Association is anxious to secure for the graduates a voice in the government of the university. This is a natural desire, and when we look at the privileges of the graduates of other universities, and the moderation with which they have been exercised, we cannot see why the authorities at St. Andrews should hesitate to grant all that is asked. Concession is the order of the day at all the universities, and the House of Commons, if appealed to, is likely to make a clean sweep of all obstructive bodies. We should therefore advise that the flag of "no surrender" should not be raised, for so sure as it is unfurled it will lead its followers to destruction. It will bring at once to the front a united phalanx of hundreds of graduates, whose resistance to one or two petty oligarchies will be pronounced by the Parliament and the people as both natural and just. In these days the assertion of *privileges* upon the part of the few only provokes the demand for *rights* on the part of the many. Let all obstructives bear this in mind, and while they may, act justly, and so get the credit of also acting generously.

After the conclusion of the debate on Parliamentary matters, in which many well-known graduates took part, the President brought forward his scheme for a registration of disease. In a few pointed remarks he urged the utility of such a collection. He was authorized by the Society to head a deputation of its Council to Lord Devon, with a view of obtaining such a modification of the form of record kept by Poor-law Medical Officers as would answer this important national purpose. Of course the Association recognizes and urges the necessity of paying Poor-law Officers for the extra work. We know it would be well done—no one doubts that it would be useful, but few hope that the Poor-law Board will entertain any plan for putting a few coppers into the pockets of the disgracefully over-worked and under-paid Poor-law doctors of the kingdom.

THE NEW REGULATIONS FOR ENGLISH POOR-LAW MEDICAL OFFICERS.

The regulations lately issued by the Poor-law Board, impose a fresh series of obligations on the unfortunate men who serve in the medical department. It is bad enough that these over-tasked officials should have new burdens laid upon them, but besides this they are to be deprived of any security that they will be supported if they attempt to obey. They are to inspect the institutions with which they are connected, they are to report upon the conduct of the Guardians who employ them, but these Guardians are to retain the power of dismissing them for their impertinence. In process of time we shall discover what kind of a being the Poor-law Board is looking for as Medical Officer. It is clear that he has long ago been expected to be so angelic as to disdain all creature comforts, to need no food, to require no rest. He ought to rejoice in the privilege of attending the pauper at a loss, and if he can accept, as the best of stimulants, the kicks which the severely cruel Mr. Fleming may think fit to administer, he may possibly be suffered to enjoy them during the pleasure of that awful functionary. If, on the contrary, he should cherish the delusion that the Poor-law doctor is "a man and a brother," and so dare to assert his rights as such, the fate of Dr. Roger's will soon be his, and his Guardians will have as great a triumph as the directors of the "Brimstone Hotel."

It seems strange that with two medical men, whose duty it is to advise the Poor-law Board on all questions, such failure of bare justice should continually occur. We remember very well, before these gentlemen were selected for their responsible positions, that such appointments were expected to afford protection to the hard working officers, whose groans filled the whole profession with indignation. When they were appointed, hope at once rose, but how bitter has been the awakening from that dream! In putting on the official cloak, they seem to have put off all care for the sorrows of their profession, and lost all interest in its honour. Had they but done the work for a few months, which their poorer brethren are compelled to do, are doing year after year, they would not so easily forget the toil, as to stand by and suffer an addition to be made to it without remonstrance.

As we have urged over and over again, the inspection required is that of well-trained, independent men, and the scheme to palm off for it a mere supplementary report, procured from the over-tasked medical officers, and at their personal peril, is neither more nor less than an attempt to hoodwink the public. That the plan will meet with the reception it deserves, we hope and believe. That all may understand the gist of it, we add the following remarks, which have been forwarded us by a correspondent, well acquainted with the whole subject :—

"The truth is, that this is an attempt on the part of the central board to supplement the now notorious deficiencies of the lay inspectorate by imposing unpaid, onerous, and personally penal obligations upon the unfortunate union medical officers without holding out to those gentlemen the least hope that they will be protected in any way, provided they honestly discharge the duty. That such services should be performed, and that medical officers should be secured in every way from the wrath of the local boards cannot be doubted; but what hope is there that such will be the case so long as the central poor-law permanent staff remains as it now is—so radically, incurably, inefficient, and corrupt.

"In many unions the regulations cannot be carried out with even an approach to safety to the medical officers—viz., in those where the appointments are only for a stated time, and not for life.

"I know not to which of the medical advisers of the Poor-law Board the proposal of these additional duties is to be attributed. Perhaps it has had a joint parentage. But whether it proceeds from one or both, we can now plainly see that the selections of medical inspectors made by the late and present governments have been most unfortunate for the interests of poor-law medical officers generally. Their unfitness for their office unquestionably arises from the fact that owing to their education and previous pursuits these gentlemen have not been, and, what is more never can be *en rapport* with those who bear the heat and burden of poor-law medical work. The old association of poor-law medical officers, of which Mr. Griffin was chairman, always urged the appointment to the office of medical commissioners to the Poor-law Board of a gentleman who had seen some lengthened service under a local board, and who would thereby be rendered capable of appreciating the difficulties, and of sympathizing with the troubles of his less fortunately placed brethren. Had such been done I am convinced that these new regulations would never have been issued without a distinct intimation from head quarters that the officer should be protected in complying with them, and provision being made that these extra services should be paid for.

"In conclusion, I cannot resist asking whether a great outcry would not have been raised in the sister services of the army and navy if the directors-general and inspectors were chosen from the ranks of hospital physicians and surgeons who had never seen the interior of a military or naval hospital, and who were wholly unacquainted with the necessary details of such services.

"Yet the same thing has been done by the Poor-law Board; and the interests of 3000 medical officers have been confided to gentlemen who have little sympathy with, or knowledge of, the position and duties of these officers."

Notes on Current Topics.

The Public Health.

The rate of mortality continues to be much the same as for the last few weeks. The annual rate was 25 per 1000 in the large towns together; while the rate in each was as follows:—London 22; Edinburgh 26; Dublin 27; Bristol 28; Birmingham 26; Liverpool 29; Manchester and Salford, each 29; Sheffield 21; Leeds 23; Hull 20; Newcastle-on-Tyne 22; Glasgow 32.

There were 1346 deaths registered in London, which is 201 less than the average number of this week in the year. The deaths from zymotic diseases numbered 252, the average being 326. Of these 17 are registered as due to small-pox, 46 to measles, 12 to scarlatina, 11 to diphtheria, 58 to whooping-cough, 24 to fever, and 23 from diarrhœa. Of diseases of the chest we note in the returns 186 deaths from phthisis, 147 from bronchitis, 70 from pneumonia, and 65 from diseases of the heart.

Health of Madras.

We have several times had occasion to comment on the sanitary condition of our Indian dependency, and now we wish to draw attention to a report of Mr. Ellis, sanitary commissioner of Madras, which has just appeared, and some of the figures in which are of unusual interest. The population of the districts from which returns were received in 1866 was 21,844,694, and the deaths were 586,225, or 26·8 per 1000 of population. The deaths from cholera were 197,977, or 9·1 per 1000 of population. The districts which suffered most severely were Ganjam, in which the death-rate was 55·3 per 1000; and Bellary, 41·8 per 1000, of which 19 per 1000 arose from cholera.

Some allowance must be made in these figures for the necessarily considerable number of cases entered as cholera which were due to other causes, such as starvation, but the termination of which would be marked by alvine flux. It should also be mentioned that imperfections may result in the statistics from ignorance or want of practice in those who collect and compile them, since 1866 was the first year in which the deaths of the civil population were returned. Besides cholera, fever also caused severe ravages—107,846 deaths being referred to that disease.

If we turn to the *town* of Madras, we find that imperfect death registers have been kept since 1855. Attempts to remedy the sanitary conditions of the town encourage us to hope that the returns may in future be more favourable.

The population of the town in 1866 was estimated at 450,000; the deaths were 13,881, affording a death-rate of 31·2 per 1000 of population, against an average rate in the six previous years of 28 per 1000. The deaths from fever were 2256, against 2190 in 1865; diarrhœa, 949, against 1062 in 1865; dysentery, 1316, against 1159 in 1865; small-pox, 103, against 44 in 1865; and cholera, 2984, against 944 in 1865.

Besides the improvements being effected in drainage, water supply, and other sanitary conditions, it is to be observed that the year was peculiarly unhealthy. Both cholera and fever were epidemic, and in some parts famine added to the people's sufferings.

For these reasons, we may fairly hope that the mortality in future will seldom be so high.

Turning now from the civil population, we find that the statistics relating to the European army serving in the Presidency of Madras and at Port Blair, Singapore, and Penang during the year 1866, return the strength of the troops at 11,498. The admissions into hospital were 16,795; the average number daily sick was 779, or 68 per 1000; and the mortality was 250, or 21 per 1000 strength. The number invalided for discharge was 645, or 57 per 1000 strength. The sanitary condition of the European army showed a slight retrogression in 1866, but the mortality contrasted favourably with that in the other Presidencies, the death-rate per 1000 strength being 17·9 in Madras, 29·9 in Bengal, and 23·4 in Bombay. The strength of the native army in 1866 was 32,121, but the statistics of the medical returns related only to 27,217, of whom 22,135 were admitted into hospital; the daily average sick were 870, and the deaths were 375, or 13·7 per 1000 strength.

It may interest some to compare with this the account of the criminal population, which numbered 9457. The death-rate was 124·5 per 1000.

At Berhampore there was over-crowding and bad ventilation in the gaol, while famine prevailed for four months. The mortality was 461 per 1000. This was not the worst place, for at Tellicherry the mortality reached the frightful figure of 783. Surely there is much to be done yet.

The Royal College of Physicians of London.

In spite of the prognostications of our contemporaries, the Fellows of the College of Physicians have re-elected Dr. Alderson president, by an overwhelming majority. It is rather amusing to be told that "this fact is in apparent opposition to the perfectly correct statement" previously put forward, with a view of influencing the election, especially when two journals bring forward the same name as a favourite. Let it pass, however. People who indulge habitually in prophecy do not produce much effect by their lucubrations. We have heard it whispered that there is no more truth in the talk about Dr. Alderson's conservatism than in the predictions that have been falsified, and we hope that this may prove to be the case.

Royal College of Surgeons of England.

The contest at the July election still excites much interest, though there is little to call for remark since we last wrote upon the subject.

The candidature of Mr. Erasmus Wilson assumes a more important aspect than was expected, for besides taking his stand as a representative of science, he has sketched a programme so liberal that it cannot fail to secure him the adhesion of a large party, and compel his opponents to speak out. There is one point which we think deserves further elucidation—viz., the association of fellows which Mr. Wilson wishes to see established. What does he mean? We believe there was once a Fellows' club or a Fellows' association. Would Mr. Wilson revive that? or would he establish another on a broader basis? We think the Fellows would like to hear more about this.

King's College.

The appointments at King's College and its hospital seem always to be a source of complaint, and no wonder; for some of them have been most transparent jobs. Mismanagement, or something worse, again makes King's College the talk of the week. The claims of Dr. Conway Evans who, in the zealous discharge of his duties as assistant-physician for more than twelve years, has proved himself an able clinical teacher, seem to have been once more forgotten. Dr John Harley has also been for many years connected with King's, during which he has proved himself an able investigator. It was said to us the other day that some men would rather be doorkeepers at King's College than sit in the seat of honour elsewhere. Verily, the institution has a knack of retaining, as her doorkeepers, men who elsewhere would reap the reward that is their due. Still the quotation about "hope deferred" should not be forgotten.

The Case of Dr. Stirling.

A correspondent of the *Army and Navy Gazette* relates how Commodore Randolph has ejected from office Staff-Surgeon Stirling, M.D., under pretence that this gentleman had not been sufficiently attentive to another naval officer, who was ill under the Commodore's roof. The doctor seems to have been under the impression that sailors dangerously ill should have precedence of a captain less severely afflicted. In fact, it would seem, that the gravity of the said captain's case was not increased, in the doctor's eyes, by the fact that he was the Commodore's friend. What obliquity of vision in a professional man.

As Dr. Stirling left the Cape for England by the last mail, we shall no doubt shortly hear more of the matter. It cannot rest where it is.

The Epidemiological Society.

On the 6th inst., Mr. Radcliffe read a paper on Cholera, in which he had collected all the facts of the late epidemic that he could rely upon. A discussion of a somewhat desultory nature followed. Several speakers directed their observations towards the question of contagion. It was objected by some that the paper did not broach this doctrine. Others thought that although full of facts, there was an evident leaning in the paper to the theory of contagion, and therefore, they proceeded to show that the facts were equally in accordance with the opposite view. This led to the question of quarantine, which was denounced as erroneous in theory and useless and oppressive in practice. The debate is adjourned, and we hope may be fairly carried out, for there are few more important questions that could occupy such a society. We should be glad, indeed, to see this question of quarantine sifted to the bottom by the society.

Mortality of Scotch Children.

In 1867, of all the deaths in the eight principal towns of Scotland, 43 per cent. were those of children under five years of age. Further, a comparison of the deaths with the population, shows that the mortality per 1000 of children under five, in the several towns, was: in Perth 50, Aberdeen 63, Paisley 79, Edinburgh and Greenock 87, Leith 88, Glasgow 96, Dundee 106. Here is an ascending scale, at the foot of which is Perth, while Dundee is at the top. In this last town the infant mortality is more than double that of Perth. Figures like these should excite inquiry. No slight circumstances will account for them.

History of Anæsthetics.

Mr. Syme thinks there is a prevalent erroneous understanding with regard to the history of this subject. Accordingly he has thought it right, in justice to our Transatlantic brethren, to issue, in pamphlet form, an extract from the work of the late Dr. Mason Warren, who details the early discovery of the power of ether by the dental practitioner, Dr. Morton, and the earliest use of the agent in surgery, which was by Dr. Warren and his colleagues in the Massachussett's General Hospital, whence it spread throughout the world, and was shortly followed by the discovery of chloroform.

In noticing this, we may mention that Dr. Mason Warren, like many of his countrymen, prefers ether to the more pleasant smelling, but, as he believes, less safe anæsthetic.

Those who have not looked up the history of anæsthetics, will be pleased to meet with the extract Mr. Syme has issued (through Messrs. Edmonston and Douglas), from the "Surgical Observations" of Dr. J. Mason Warren.

Diarrhœa: Dr. Chapman's Therapeutical Method.

Since publishing on the 1st inst. the case sent to us by Dr. Fitzgibbon, of "choleraic diarrhœa, which had resisted other treatment, checked by the application of Chapman's ice-bag," we have received from another source, information confirming his report of its action. Dr. J. S. Hackett, Physician to the Colonial Hospital, New Amsterdam, Berbice, British Guiana, has written to a friend, who has placed the information at our disposal, that, having read

with great interest Dr. Chapman's treatise on Diarrhœa and Cholera, he has been induced to put the doctrines in that work to the test of experience, and that the application of the spinal ice-bag was followed by "marked benefit in all the cases" in which he used them. . There was no cholera at Berbice at the time he wrote, but in the treatment of diarrhœa by the method in question "I have not," he says, "been disappointed."

When reviewing Dr. Chapman's work on the subject, we expressed our admiration of the ingenuity of his theory, as well as of the clear and logical form in which it is expounded, and recommended it to the careful attention of the profession. The facts we now mention seem to justify that commendation, which is strengthened by the evidence given on the 13th ult., at the Surgical Society of Ireland, that the spinal ice-bag does really exert an appreciable physiological and therapeutical action.

According to Dr. J. H. Benson, it cured a case of obstinate suppression of the menses, accompanied with severe and continuous headache, and greatly benefitted a patient suffering from partial hemiplegia, after other remedies had been tried in vain ; and Dr. Hewitt informed the Society that he had used the ice-bag in a case of delirium tremens, after capsicum had failed, and tartar emetic and opium had seemed to do harm, and found that it checked perspiration, cured the tremors, and produced sleep almost immediately. As he observed, the results in this case were precisely those attributed to the remedy by Dr. Chapman, and we agree with him in thinking "they are fraught with interest." Indeed, it seems impossible to withstand the evidence, now fast accumulating from different sources, that Dr. Chapman's pathological theories have led him to the discovery of a therapeutical power of the first magnitude, and possessing a very wide range of application. We again commend it, therefore, to the attention of our readers, with the earnest advice to test its efficacy as a remedy for diarrhœa ; for if, happily, a large and varied experience should prove that the spinal ice-bag is really remedial of this disease, it will, while countenancing Dr. Chapman's theory of the essential nature of diarrhœa and cholera, afford strong hope that we may find in the spine-bag the most potent remedy for cholera itself.

The Royal Visit to Ireland.

We revert with pleasure to the agreeable topic of the visit of their Royal Highnesses the Prince and Princess of Wales to Ireland, and the approaching reception of the Prince at the Royal College of Surgeons. The Council has erected, for the accommodation of the Fellows and Licentiates to view the installation procession, three large balconies ; the interior of the College has undergone redecoration, and the address to His Royal Highness was adopted at the last meeting of Council. The hope which we ventured to express last week, that Mr. Adams, the President of the College, and Surgeon-in-Ordinary to the Queen in Ireland, may be deemed worthy of a special mark of distinction at the hands of the representative of the Crown, has been most warmly entertained by the College, and has derived strength from the fact that, although the medical section of the profession has been distinguished in the person of Sir Dominick Corrigan, the Physician to Her Majesty in Ireland, the medical baronetcy rendered vacant by the death of Sir Philip Crampton never was filled up.

The gracious act of honour towards Mr. Adams which we have indicated, would be most fittingly supplemented by the election of a Surgeon-Extraordinary in the place of the late Dr. O'Bierne, and we cannot hesitate in pointing to Mr. Porter, the Vice-President of the College, as being most justly entitled, both by his professional position in this capacity, as the senior surgeon to the County Dublin Infirmary, and as an adroit and advanced operative surgeon, to such a decoration.

The Election to the Meath Hospital, Dublin.

The choice of a Surgeon to occupy the vacancy caused by the transference of Mr. William Stokes to the Richmond Hospital, took place on Saturday last, and excited much interest amongst the profession in Dublin. The names of many gentlemen had been mentioned as either actual or probable candidates, including those of Dr. Stronge, late of Belfast ; Dr. Mapother, Professor of Anatomy and Physiology in the Royal College of Surgeons ; Mr. Tufnell, Surgeon to the City of Dublin Hospital ; Mr. Richardson, of the Adelaide Hospital ; Mr. White, of Jervis-street Hospital ; Mr. Mayne, son of the late Dr. Robert Mayne ; Dr. P. C. Little, and many others. As nearly three months intervened between the appointment of Mr. W. Stokes to his new position and the election to his office at the Meath, there was ample opportunity for the consideration of the claims of various candidates, and the interposition of religious considerations by certain members of the Town Council, from whom the hospital derives an annual grant of £300, added to the conjectures as to the probable result.

The event has resulted in the election of Dr. Stronge, of whose qualifications and previous services we append the following notice from the Medical Directory :—"James W. Stronge, 49, Great George's-street, North, Dublin, M.A., M.B., T.C.D., 1841; L.R.C.S.I., 1843; L.M., Dublin Lying-in Hospital, Mem. Path. Soc., Dublin ; Med. Officer Health, Belfast ; late Surgeon Ranensdale Dispensary, and Res. Surg., Whitworth Hospital, Dublin Contrib.—'Remarks upon the Epidemic Fever and Bowel Hæmorrhage of 1846-47,' *Dublin Quarterly Journal.*"

Original Communications.

DISEASES OF CHILDREN: CONVULSIONS.

CASES AND OBSERVATIONS.

By P. C. LITTLE, F.R.C.S.I., L.M., &c.

The study of infantile disease is daily attracting much attention. It affords a wide and fruitful, yet comparatively uncultivated field of observation. The ancient popular prejudice, that only old women can understand the ills of childhood, is fast declining, and the necessity of scientific knowledge for the proper treatment of disease, assailing life from its budding to its decay, is now very generally recognised. The greater value hitherto attached to adult existence, influenced our predecessors in devoting themselves almost exclusively to the morbid conditions of that state, although, in social and national aspects, the lessening of infant mortality is of vast importance. Great and special difficulties oppose our efforts in this direction, yet the very magnitude of those obstacles, and the helplessness of the little creatures whom we desire to preserve, and who may one day "fill our places," should animate us in our labour of love. Through the courtesy of The Medical Press and Circular, of which I have before so frequently availed myself, I purpose offering occasionally, from my

practice, contributions upon this most interesting class of diseases.

I now beg to present some cases of Convulsions, a fearful malady, prevalent in early life, and too often the herald of death and sorrow. This disease has been divided in so many ways by authorities on the subject, that it is necessary I should here state what classification I adopt. I have selected the following, which is based on pathology, and sanctioned by Dr. Churchill, a name in which Irish medicine is honored, and which will ever be associated with the names of West, Graves, Gölis, Rilliet and Barthez, in connection with infantile disease.

1. *Primary or Essential Convulsions.*—Caused by irritation, as teething, fright, &c.

2. *Sympathetic.*—Occurring in the progress of other ailments, as whooping-cough, diarrhœa, fever, &c., excepting diseases of the head or spine.

3. *Symptomatic.*—Arising from disease of cerebral or spinal organs, as tubercular meningitis.

PRIMARY CONVULSIONS.

Case 1.—Feb. 15.—At half-past five A.M., I visited M. C., a female child, aged a month, suffering from convulsions. The infant appeared lean, immature, and exhausted. It lay in the nurse's arms, its head thrown backwards, limbs extended, thumbs and great toes crooked. It was quiet, but rather wakeful, at one time widely opening its eyes, and then dozing asleep, during which it sighed heavily. The skin was dusky-looking, dry, wrinkled, and warm; feet cold; head very hot, fontanelles normal; face dark, sunken; tongue bluish; mouth with a painful expression; eyes symmetrical, conjunctivæ blood-shot, pupils natural, highly sensitive to light. Pulse weak, irregular, about 140; heart and lungs sound, but feebly acting; spine congested, its temperature exalted; bowels and stomach tender on pressure; abdominal muscles in tonic spasm; no paralysis. The stools were scanty, light grey, mixed with slimy matter, and passed with much straining; urine nearly colourless.

The following is the history of the case:—The infant was born at eight months. Its parents were very young. The mother, a rather delicate primipara, was scarcely eighteen years of age when I attended her upon this child, just a month ago. She attributed her premature confinement to anxiety at the serious illness of a near relative. Nothing unusual occurred during the labour. At birth the infant seemed very thin, poor, and undeveloped. The mother had no milk for it. I therefore recommended her to provide a wet nurse; or, in the event of her not procuring one, to bottle-feed the baby on pure fresh milk, with hot water and sugar added, as hereafter described. She, however, acting on the advice of a nurse who thought such diet not nourishing enough, fed the infant upon bread, biscuit-powder, and milk. The bowels and stomach soon became deranged. Peevishness, constipation, and flatulence followed. The child wasted and pined away, and within the past week was slightly convulsed three or four times. Last night, about twelve o'clock, it got a severe attack of general convulsions, which continued for about ten minutes. The fit was immediately preceded by great restlessness, was accompanied with strong excitement of the voluntary muscles, and on its subsidence the baby seemed faint, breathless, and inclined to sleep, as remarked. A second, more prolonged and violent, paroxysm recurred a short time before my visit.

My immediate treatment consisted of—firstly, a warm bath for about three minutes; sinapisms to the abdomen and spine, from occiput to lumbar region; a lotion of spirit and water (equal portions) applied to forehead and fontanelles, and the following:—

℞ Pulveris rhei gr. iij.
Calomelanos,
Sacchari albi aa. gr. ij.
Pulv. aromatici gr. j.

Misce fiat pulvis. Statim sumat.

A tea-spoonful of castor-oil to be given in two hours afterwards. The infant to be wrapped in flannel, and a good wet nurse provided forthwith.

Mid-day.—An excellent nurse has been procured. Since morning the convulsions returned twice—the last time with great severity. The child seems, however, much improved. The bowels have been evacuated of a quantity of offensive whitish stools; tenesmus continues. The pulse is 130, more natural; skin moist, head cooler, eyes more lively; the lotion quickly evaporates on the forehead. The abdomen is not so hard and tender, its muscles less rigid. I ordered a warm linseed cataplasm over the bowels, and this medicine:—

℞ Hyd. cum creta gr. iij.
Sacchari albi gr. ij.
Pulv. aromat. gr. j.

Misce fiat pulvis. Tales duodecim mitte, quorum unum tertiis horis capiat.

Midnight.—The bowels have been again free, the motions are curdy and slimy; the head and whole body of natural warmth; stomach and bowels soft; sleep tranquil; appetite ravenous; had one strong and protracted fit at six o'clock in the evening.

The skin of the abdomen being tender from the poulticing, I ordered it to be smeared with sweet oil and covered with French wadding. Continue the powders.

16th.—Is better; had two attacks of the spasms during the night, the first at one o'clock, the second, a violent one, at day-break. Treatment as before.

17th.—Is very well to-day; stools greenish; has had no fit since my last visit; enjoys its food and sleeps soundly. The powders to be given only three times a-day.

18th.—The stools are natural; the child is in perfect health and spirits. Discontinue the medicine.

On my calling two months after this, I found that the infant had had no return of the fits, and had grown stout and strong.

I have been particular in detailing this case, as it appeared typical of its kind.

SYMPATHETIC CONVULSIONS.

Case 2.—J. G. N., a male child, aged 11 months; hitherto healthy, now suddenly affected with fearful convulsions, especially of muscles of face, neck, and arms. The surface of the body is hot, the head remarkably so; face dark and congested; eyes closed, sensitive to light, conjunctivæ injected, pupils natural; pulse weak and rapid; respiration hurried; bowels hard, distended with flatus, and long constipated. The fits recur at irregular intervals, at present two or three times in the day, continue from three to five minutes, and leave the little sufferer weak and irritable. Some time since, he got his incisor teeth easily, now the molars seem to be coming to the surface. The gums are tumid, tender, and red; no tooth can be felt beneath. To relieve the congestion, the lancet had been freely used before I was in attendance, but so far from doing good, it seems to have increased the frequency and severity of the spasms. There is no hereditary disease in either parent, that I could learn. I prescribed immediately the mercurial purgative as in Case 1, and castor-oil; also, a large sinapism to abdomen. The bowels were well evacuated, stools hard, and slimy. The intervals between the fits grew longer, the attacks less severe. They returned occasionally, however, for thirteen months; were always amenable to the aperient mentioned, and disappeared entirely on the completion of dentition. The child has become a fine healthy fellow.

Case 3.—L. N., æt. eight months, sister of the last patient; afflicted with spasms of upper extremities, and hideous contortions of the features; winking, fixing of eyes, pupils turned upwards under lids, sensitive to light, and contracted; skin very hot; face blue and swollen; bowels constipated and tender on pressure. She, too, had cut her front teeth easily, but her gums were tender; the molars yet impalpable. In her case the paroxysms were more violent and repeated, but more brief than in her brother's.

She had had twenty-three fits in the forty-eight hours preceding my first visit. Subsequently neglect of keeping the bowels free, brought on an attack at times during five months, at which period the teething ended, and with it the convulsions. The treatment was the same as in the previous case.

Case 4.—Isaac B., æt. four months, attacked by convulsions during teething. On my visit his eyes were fixed, insensible to light, the lids easily opened, pupils natural; face thin and sallow-looking; bowels not free; stools slimy and green; pulse very small, too rapid to be counted; skin dry and hot. The fits recur two or three times every day, and are growing more severe. The incisor teeth are out, the molars approaching the gums. The parents are healthy. I followed the same treatment here as in Case 1, only, however, giving the hyd. cum creta powders for about three days, when the fæces became more natural. Slight attacks occurred now and then for nearly four months, on the bowels being confined. The child is now robust.

Case 5.—June.—Ed. F., æt. five years; always a delicate boy; had been ill for three or four days with febrile symptoms, attributed to the heat of the weather. He then complained of headache, drowsiness, sickness of stomach, and thirst; skin burning, bowels constipated. These conditions had increased so rapidly, that on the day of my visiting him, he had lost consciousness, hearing, sight, and speech. When turned or moved he screamed fearfully. He drank automatically, and relapsed into a comatose state. Frequently he had strong convulsions of right side of the body, and particularly of right arm, attended with shrill, pitiable cries. The pulse was feeble, rapid—about 160; respiration 40; heart's action weak; bowels tympanitic; urine passing unconsciously; tongue dirty; sordes on teeth. The pupils—unaffected by a bright light, were fixed, widely dilated, and equal; the conjunctivæ blood-shot.

An infant brother of his died, sometime ago, of water on the brain. The parents are both affected with strabismus, one very much so; otherwise, they are healthy.

I ordered a terebinthinate enema at once; the head to be shaved, ice applied, and a powder, three times a day, as follows:—

℞ Hyd. cum creta gr. iij.
Pulv. jacobi veri gr. ij.
Pulv. aromatici gr. j. Misce fiat pulvis.

I allowed cooling drinks, and chicken-broth. In about a week the gums became slightly affected, though the symptoms were much the same; the insensibility and screaming continued; the temperature of the body was diminished; tongue brown. I advised a blister to the head, a dressing for it of unguentum hydrarg.; the powders still, and a little brandy very frequently. He used so freely the spirit, that for the next fortnight his consumption was half a-pint in twenty-four hours, I was informed. After the twentieth day, he gradually returned to his senses, regained his appetite, and made a good recovery. He has ever since enjoyed health. He, however, appears somewhat dull in comprehension, and has a remarkable dilatation of the pupils.

SYMPTOMATIC CONVULSIONS.

Case 6.—I visited P. F., a male, aged 10 months, with convulsions of upper half of body. The head seemed unusually large transversely, fontanelles bulging and pulsating. He lay listlessly in the nurse's arms, with opisthotonos; eyes half open, glassy, pupils slightly convergent, dilated, insensible to light; lips asunder, now and then quivering; hands bent inwards, fingers crooked; respiration feeble; pulse slender, very quick; skin cold, damp, wrinkled; features pale, apparently œdematous, blue around eyes and mouth; veins of temples and forehead dark, prominent; abdomen large, pendulous; urine abundant, stools watery,—both running away. The spasms recur four or five times in the day, are increasing in length, and during the attacks the eyes wink quickly, the arms syncronously jerk upwards.

For a few days I prescribed grey powder, and counter irritation by the frequent application of small blisters to the head; and a generous diet of chicken-broth, wine, &c., but finding no satisfactory result from this course, I substituted for the powders, the syrup of the iodide of iron, which I had often seen beneficially used in such cases, at the Institution for Children, by my distinguished friend Dr. Moore. This remedy also proved useless, as the child sank rapidly, and died on the eighth day of my attendance.

Much light is thrown on the case by the annexed particulars. The child was considered very healthy at birth, subsequently got incisor and some molar teeth without much trouble, and up to its eighth month throve well. It then began to decline, had occasional derangement of bowels, irregularity of appetite, and restlessness. About a week before I was called, it began to roll its head, toss its arms about, and, on the day before my first visit, convulsions appeared. Its father has a strong constitution. The mother's family are consumptive. Two former children of these parents died at an earlier age of water on the brain. The present case occurred in my practice nearly five years ago, the notes of which I have given. In a few months after that time, the mother being pregnant, consulted me with a view of anticipating, if possible, a similar fate to her coming infant, as had befallen her previous children. I ordered her cod-liver oil, iron, generous diet, and change of air, by which means she grew very hearty, had a female child at eight months, which is at present about four years old, and is smart and strong.

Case 7.—Jan. 10—At 7 A.M., J. J., a lad aged 7 years, while in bed, became unexpectedly ill with general convulsions, loss of consciousness and sensibility, which had continued with scarcely any intermission, up to my arrival at 8 A.M., when his condition was lamentable. His parents were endeavouring to control his violent movements, and to prevent his tossing himself out on the floor. His decubitus was supine, with pleurosthotonos of right side. I observed that the right arm was most strongly convulsed. The tongue was protruding, swollen, and lacerated; face dusky, congested, its muscles affected with a spasmodic action, as if under electric shocks; eyes firmly closed, pupils contracted, insensible to light, conjunctivæ suffused; skin, especially of head, hot; hands clenched; respiration hurried, irregular; heart's action rapid, nervous; pulse small, quick—120; bowels soft, regular. I could find no tumours at nervous centres, or peripheries. There was no hereditary disease in his family, and he had been thought a very healthy boy. A few days ago he caught cold, since which he has been dull, and fond of the fire. On inquiry, I learned that for more than a year he had had otorrhœa of left ear, which, however, had ceased lately.

I ordered four leeches to be applied over the left mastoid process, sinapisms to the calves of the legs, and, should consciousness return after the leeching, I prescribed to be administered—a brisk aperient of rhubarb and calomel with castor-oil in two hours subsequently.

In the evening I found him in a very satisfactory state. I was informed that before the leeching had been completed, the convulsions ceased, consciousness returned, and soon afterwards the otorrheal discharge re-appeared. He now complained of soreness all over, pain in the left ear, noise in the head. Having examined with the speculum the external meatus of the left ear, I observed that the mucus membrane and the tympanum were inflamed, and covered with thin purulent matter. By continued counter-irritation over the left mastoid process, syringing with suitable astringent lotions, and by general tonics, the boy, in a few weeks, perfectly recovered his health.

The obstacles to a correct diagnosis in this class of diseases are many and peculiar. Amongst the latter is commonly, inability of the patient to make known his ills. His frail organism, ever changing, developing, susceptible of disturbance from slight causes, yet so wonderfully recup-

rative, also increases our difficulties, and shows the necessity of careful examination of the sensible phenomena of the case, and of precise knowledge of the antecedents of the little sufferer. In him trifling violations of nature's laws are visited with severe penalties. While, on the other hand, our efforts to restore his health are in general amply rewarded. Guided by those views in my investigations, I was led to conclude that the prime pathological origin of the convulsions in each of the foregoing cases was as follows :—

Case 1.—Irritation of digestive organs, caused by improper food.

Cases 2, 3, 4.—Dentition, and absence of proper counter-irritation, *e.g.* of bowels.

Case 5.—Fever, which preceded and attended the paroxysms.

Case 6.—Tuberculosis. The hydrocephalic evidences were, bulging of fontanelles, dilated pupils, convulsions, history, &c.

Case 7.—Cerebro-meningeal derangement in left hemisphere, probably near medulla oblongata. The violent action of right arm, and the history decided my diagnosis.

One of the most ordinary causes of disease in infancy is unsuitable nourishment, which often creates derangement of bowels and convulsions. Case 1 is an example of this, and of the restorative power of a mother's milk. In the absence of the latter, I have in many instances found that, two-thirds of fresh cow's milk, with one-third of boiling-water and a little sugar,—combined, make an excellent substitute for at least the first three or four months, after which the infant tires of it, unless a little arrowroot, corn-flour, biscuit powder, or the like be added. Human milk, unlike that of herbiverous animals, is produced from such a variety of *ingesta* that it seems peculiarly adapted to the demands of the infant economy, with which it always agrees; and experience testifies to its capacity of alone supporting mature life, and supplying all its wants. If the child suffer from flatulence, irritation of bowels, and diarrhœa, or be of low vitality, from five to ten drops of brandy may be added to each bottle of food, with great advantage. I have so frequently observed the efficacy of this simple adjunct, under such circumstances that, I rely upon it to the exclusion of oil of anise, syrup of poppies, "soothing syrups," or other *nostrums*, in high repute with "baby-farmers" and indolent nurses, but which too often purchase a temporary quiet at the cost of the general health, and sometimes of life itself.

The wide-spread, but happily declining, prejudice against bottle-feeding, rests chiefly upon examples in which there was negligence, or ignorance as to the details of that method of nursing. What wonder that bad consequences should follow the use of sour, reboiled, or adulterated milk, unclean bottles, impervious or worn-out mouth-pieces and tubes ! I have again and again traced the failure of this system of feeding to some of those sources, and as often have I been gratified with the success resulting from attention to the following directions :—

1. Make only as much food as may be required for present use.
2. Let the milk be pure, fresh, and unboiled.
3. Add to it one-third of boiling water on going to feed.
4. Add also a little sugar, brown or white, according to the state of the bowels.

The bottle and its fittings should be always perfectly clean. This may be more easily secured by having two bottles, one of which, on being used, should be immediately rinsed with warm water, and kept in a basin of cold water until again required.

Dentition is a fruitful originator of convulsions, as exemplified in Cases 2, 3, 4. And here I must record, as the sum of my experience, a humble protest against the too prevalent, indiscriminate, and, I had almost said inhuman, practice of scarifying the gums during this natural process. It may be noticed that, in Case 2, that proceeding did not relieve, but intensified and multiplied the fits. I have invariably observed that, in children otherwise healthy, the excitement of teething and its occasional consequence—convulsions, may be controlled and finally subdued, by keeping the bowels rather free, on the principle of counter-irritation and derivation, I presume. Whether such be the explanation or not, it seems consistent with natural laws, and with our physiological knowledge, that, as far as possible, local interference with such developments as teething ought to be avoided; and that, we should try to modify any unusual excitement during that function, by constitutional means, after the manner in which our venerable instructor nature, is wont to assuage such ills. Thus, during dentition, we observe her counter-actions upon cutaneous surfaces, causing white or red gum-rash, crusta laetea, &c.; or upon mucous membranes, as of the alimentary canal, the bronchi, or nares, producing diarrhœa, bronchitis, or a semblance of coryza. Such may be called the safety-valves of dental irritation. This appears to me to be a point of the greatest importance in connection with the management of dentition, and I would respectfully solicit observant practitioners to scrutinise it more thoroughly in the light of natural and morbid physiology, and with the view of reforming the old sanguinary treatment.

The occurrence of convulsions in the course of infantile fever is unfrequent, and in my opinion is not always a mere sympathetic expression. I should rather say, it is more commonly a development, at a nervous centre, of the morbid influence which imbues the whole economy. And as such, in Case 5, my treatment was specially directed to the removal of the nervous lesions, since I could not cut short the fever. The early announcement of the typhoid character of the latter was valuable, as indicating the means to be employed, and in particular the necessity of timely stimulation, for the remedying of the cerebral complications.

As a preparation for special treatment in infantile convulsions, I have generally prescribed a mercurial aperient, and castor oil after it. In some cases, this course repeated occasionally, has been all that was required. I have always been pleased with the effects of counter-irritation, especially by sinapisms. Alteratives, such as grey powder, or James's powder, have appeared to me requisite where hepatic or gastro-enteric derangement were manifested—by the character of the stools, the skin, the rigid and sensitive state of the abdomen, and not least of all, the history of the patient, as in Case 1.

My reasons for giving such large doses, particularly of mercury, in those diseases were—1st. I made allowance for waste in administration. 2nd. Experience taught me that, in such cases, especially in teething, means unusually powerful, are necessary to divert the irritation to the bowels. 3rd. As regards mercury, it seems to me to act, in the infant system, more as an aperient, gentle stimulant, and alterative, than as a syallogogue. I consider it to be specifically indicated in diseases of local irritation, by increasing generally, the action of the absorbents, without salivation, or the other depressing effects which it produces upon adult life. Possibly, the undeveloped organic state of the infant ensures for it immunity from the objectionable effects of this medicine, in the same way in which that tender period is exempted from many of the ills which afflict more mature years.

As I have already prolonged this paper more than I had anticipated, I shall reserve for a future occasion some further remarks upon this very important subject, and particularly upon convulsions of hydrocephalic origin, which deserve a special consideration.

REBUILDING OF THE MEDICAL HOSPITAL OF THE ROYAL INFIRMARY OF EDINBURGH.—The meeting which is to be held in the Music Hall on Friday, under the presidency of the Lord Provost, for the inauguration of a fund to be raised for the rebuilding of the Medical Hospital of the Royal Infirmary of Edinburgh, will be one of the most important which has been held in this city for many years. The work to be accomplished is one of great magnitude, and the estimated cost is nearly £100,000.

REPORT OF A CASE OF CHRONIC RHEUMATISM AND DYSPEPSIA, AND A CASE OF PSORIASIS INVETERATA, SUCCESSFULLY TREATED BY MEANS OF TURKISH AND MEDICATED BATHS.

By N. J. BUTLER, L.C.P.I., L.R.C.S.I.,
PHYSICIAN TO LA MAISON DE SANTE, NORTH GREAT GEORGE'S-STREET.

My chief object in reporting the two following cases is to bring under the notice of the profession the great value, particularly in chronic forms of disease, of a judicious course of medicated or Turkish baths in conjunction with proper constitutional treatment. In London, Paris, and many of the Continental and Eastern cities, Turkish and medicated bathing is properly regarded as a remedial agent of great power, while its easy application and the comfort it affords the bather, render it a favourite remedy with both physician and patient. In Dublin, perhaps, more than any other city in the world, is the use of baths in any form regarded with a cold and passive indifference, which certainly cannot be due to their want of real merit as curative agents, nor yet to any deficiency of appreciative intelligence (if I may use the expression) on the part of the Dublin practitioners, a fact which their universal reputation proclaims. And yet, that such is in reality the case, I have upon the authority of one of the most venerable, and at the same time, illustrious practitioners in Dublin or any other city. I regard the present apathy of the profession on the subject not to any hostility upon their part to the use of baths grounded upon physiological or scientific data, but to the fact, that up to the present, the subject has never been brought under their observation, nor, I presume, are the majority aware that there is an establishment in Dublin at present second to none in the United Kingdom, and where every facility is afforded for fully testing the value of the different descriptions of baths. The first case that I will describe is that of J. B., æt 40, a man in rather comfortable circumstances, married, but with no family, had been suffering from chronic rheumatism for upwards of nine years. He was sent to me for the purpose of taking a course of Turkish baths, by an eminent provincial practitioner who had previously treated him with all the reputed specifics for the disease. When he submitted himself for examination before entering the bath, the following were the most prominent symptoms he presented—his face was thin and drawn, of an ashy hue, and cadaverous expression. The tongue was slightly swollen, covered with a thick creamy fur, and deeply fissured. The stomach was distended with gas, and the parietes of the abdomen boggy, action of the heart extremely feeble but normal; pulse at wrist almost imperceptible. He complained of great lassitude, loss of appetite, constant headache, and stiffness of the back of the neck, extending upwards to the base of the skull, while the pains in his loins, hip, and knee-joints rendered locomotion an exceedingly difficult and painful operation. After the second bath, he felt much improved in his general condition. The stiffness in his neck vanished, he complained less of headache, and his appetite improved. Encouraged by so good a beginning, he persevered, and after a short course of only eight baths, he was quite convalescent, being able to attend to his ordinary avocations with a restored appetite, and an increase of muscular strength, and an immunity from pain, which enabled him from not being able to hobble more than a few perches at a time, to walk a distance of six miles without the slightest feeling of fatigue. He continued in the enjoyment of good health up to a couple of months ago, when he was exposed to a whole day's rain, got his clothes thoroughly saturated, and, as a natural consequence, an attack of acute rheumatism, from which he has not yet completely recovered.

The next case is that of J. F., a young man, æt. 18, of fair complexion and robust constitution. When he consulted me he presented an excellent example of psoriasis inveterata. Every part of his body, except the scalp, was the seat of the disease, but it had selected the lower extremities as the particular field for its depredations—from the knee of each leg to the sole of the foot was one mass of diseased cuticle. In many places fissures of great depth and extent existed, and communicated an aspect at once repulsive and alarming to the limbs. Upon the right leg also two small, but deep, and unhealthy looking ulcers had formed, and these I found most difficult to heal. I commenced treatment by ordering him a Turkish Bath, which cleanses the skin and rids it of all extraneous or effete matter more effectually than any other agent with which I am acquainted, and by so doing prepares it for the application of more specific remedies. I then ordered him to take sulphuret of potash, bath every day for a fortnight, and at the same time I prescribed four drops of the liq. arsenicalis three times daily after food. Before the expiration of the fortnight, during which he had a bath every day, he was very much improved in every respect. The desquamation of cuticle was much reduced; the tormenting pruritus from which he had previously suffered intensely, was almost completely allayed, and the whole of the diseased surface assumed a healthier aspect. The small ulcers, however, previously mentioned, did not participate in the general improvement that had taken place, so I passed the nitrate of silver pretty freely over the surfaces, and ordered him to apply a linseed meal poultice the following night. He did so, and when I next saw him, after two or three days, the ulcers were greatly improved, and were secreting a much more healthy-looking pus. As, however, I did not quite like their appearance, I again applied the caustic, and followed it up by simple dressing. Under this treatment one of them completely healed, and the other became reduced to about the size of a split-pea. He now, unfortunately, regarding himself as completely cured, contrary to my advice, discontinued all treatment, and for a period of about three months he enjoyed almost perfect immunity from the disease. It then, however, returned, slightly, and as he neglected obtaining any advice or adopting any treatment for a considerable time after its reappearance, when he again consulted me it had assumed some of its former virulence. I at once adopted the same treatment that had before proved so successful, with the exception, that I alternated the sulphuret of potash with iodine and sulphur vapour-baths. The happiest results followed the adoption of this plan, and he is now again making rapid and certain strides towards convalescence. I should have mentioned that before he consulted me, he had been about nine months ill and had been pronounced incurable by more than one practitioner.

In my next communication I shall feel much pleasure in bringing under the notice of the profession the therapeutical action of some of the less-known medicated mineral baths, and if I can only succeed in obtaining for them a fair trial, I shall congratulate myself not only upon having in an humble manner contributed something towards the advancement of the profession, but also, on having done good service to the community at large.

Proceedings of Societies.

SOCIAL SCIENCE ASSOCIATION.

MARCH 30, 1868.

MR. BRENDON CURGENVEN read a paper on the Contagious Diseases' Act, 1866, and its extension to the civil population, of which the following is a full abstract:—

He stated that it was with the view of saving the country from the expenses attending the hospital treatment of diseased soldiers and sailors, and from the great loss occasioned by their absence from duty, that the War Office and the Admiralty in the year 1864, conjointly appointed a committee of eminent surgeons and physicians to inquire into the best modes of treating the diseases in question, and to suggest some methods of prevention.

He then detailed the following evidence given on the subject of prevention, which clearly showed that in those places, such as Malta, Gibraltar, and the Ionian Islands, where sani-

tary regulation and medical surveillance of the prostitutes had been in force, venereal diseases had almost disappeared.

"The regulations had been in abeyance for several years at Malta, and the consequence was, that from forty to fifty beds were ordinarily occupied in the Malta Hospital by patients who had contracted the venereal disease in the Island. After the regulations with reference to the police and the Lock Hospital had been in force for a few months, there was not a single patient, I believe, in the Malta Hospital who had contracted the disease in the Island."—*Admiral Sir W. Farnshaw Martin, K.C.B.*

"Females leading a life of prostitution were, from the time of the Knights, I believe, subjected to certain police regulations and to 'periodical personal inspection;' but in the beginning of 1859, it was found that the 'personal inspection' was not ordained by law, but was a traditional abuse of power, which may be put at defiance by the slightest resistance. The fact was artfully communicated to the peculiar class of persons concerned, and a general resistance was soon made to the practice.

"The awful consequences of non-restraint soon became apparent, more especially in the wards of the military and naval hospitals, and the Local Government was moved to enact the enclosed Ordinance, with the view of preventing the spreading of the disease.

"From its few and brief enactments the 'details of our management' can be very easily inferred.

"The operation of this law has had the effect of checking public prostitution to a great extent, besides of almost annihilating the disease.

. . . . . .

"The Malta law, you will observe, does not involve 'a system of legal recognition of public prostitution,' it does not 'license females to the unlawful occupation,' but simply places those who practice it under a kind of surveillance, with a view of obtaining a sanitary advantage by enforcing a measure which tends to mitigate or prevent the awful consequences of neglected syphilitic affections. Besides 'periodical personal inspection,' the Malta law also enjoins the establishment of 'Lock Hospitals,' without which the good results I have described would not have been obtained.

"Syphilitic affections, being thus timely discovered and forcibly placed under medical treatment, are generally primitive in their character, and consequently easily overcome. Cases of consecutive syphilis are comparatively rare, and none present those horrid forms so common where the disease is under no surveillance.

"Seasons have come during which the wards of the 'Lock Hospital' contained but one or two cases, and were it not for the inoculation from imported affections by foreigners and others, the disease would have long been extinct."—*Mr. Inglott, Comptroller of Charitable Institutions at Malta.*

"When I held the office of Her Majesty's Lord High Commissioner of the Ionian Islands, I gave a good deal of attention to this subject, and I found that the disease prevailed in all the larger islands, and that the troops suffered a good deal from it.

"It was determined to apply with care and vigour the powers given by the law as regarded registration and inspection of prostitutes, and all the women of the town were registered by the police, and periodically inspected by the police physician.

"This careful and periodical inspection was attended with the happiest results, and the disease may be said to have almost disappeared in the Islands of Corfu, Zante, and Cephalonia.

"In Malta, the same police regulations exist, and I know of no place so singularly free from venereal disease as regards the professional prostitutes.

. . . . . .

"The amount of disease and misery that would be prevented by enforcing a sanitary inspection of prostitutes is incalculable, and it is a subject which earnestly claims the attention of the authorities competent to deal with it."—*Lieut.-Gen. Sir Henry Storks, K.C.B.*

Such evidence as the above, together with that of several others who were examined, induced the committee in their report to recommend that—

"1st. A periodical inspection or examination of all known prostitutes be made compulsory, under a well-organised system of medical police.

"2nd. That a surgeon be appointed by Government in each town for this duty; the said examination to be made by him either at the homes of the women, or at a dispensary or hospital appointed for the purpose; and that such surgeon be provided with the necessary powers for sending to lock hospitals all women found to be diseased either with primary venereal affections or constitutional syphilis, and for retaining them until cured or restored to their friends.

"3rd. That a penal clause be introduced into the act for the purpose of punishing those who infringe its regulations.

"4th. That the operation of the act be extended to all garrison and seaport towns in the kingdom, where troops or ships of war are stationed.

"5th. That a clause be introduced for the prevention of the residence of prostitutes in public-houses and beer-shops."

The committee state that "they also feel that more particular instructions should be given to the borough police in the garrison and seaport towns, with a view to prevent the open solicitations by prostitutes in the public streets, and the scandalous and barefaced immorality which is spoken of by some of the witnesses as disgracing Portsmouth and other towns of the same class."

The Act of 1866 is confined to the following naval and military stations:—Portsmouth, Plymouth, and Devonport, Woolwich, Chatham, Sheerness, Aldershot, Windsor, Colchester, Shorncliffe, the Curragh, Cork, and Queenstown. It provides that the expenses attending the execution of the act shall be borne by the Admiralty and the War Office. It directs visiting surgeons and inspectors of certified hospitals to be appointed. It gives power to provide and certify hospitals; power to justices to order periodical medical examination of common prostitutes; power to detain them when found diseased, in a certified hospital until discharged by the medical officer; and power to punish women by imprisonment for refusing to be examined, for quitting hospital without being discharged, and for neglecting to conform to the regulations of the hospital. It provides that the justice's order subjecting a prostitute to periodical examination shall continue in force one year.

That she may obtain relief from examination on discontinuing prostitution; and that persons knowingly harbouring diseased prostitutes shall be punished.

The act was not put in force immediately in all the towns named, but its operation was first extended to Woolwich, Chatham, Sheerness, Portsmouth, Plymouth, and Devonport.

Mr. Curgenven stated that after the necessary appointments had been made, there was little or no difficulty found in enforcing the provisions of the act. The women and their haunts were equally well known to the police, and they experienced no difficulty in inducing the "suspects" to appear before the medical officer to be examined. Compulsory examination of all the women has not yet been adopted, as there would not be sufficient hospital accommodation to receive those found diseased. Those only are examined whom the police suspect to be diseased, or who are informed against by a soldier or sailor. This is one of the defects in the present working of the act, for a woman must be very ill, or show some outward sign of her complaint, to be suspected by the police; and, again, a woman may spread a considerable amount of disease before she is informed against.

One obstacle to the effectual working of the Act has been the want of hospital accommodation. About one-third the total number of women is found to be diseased. London, therefore, with about 10,000 common prostitutes, would require 2500 beds; but this number might be reduced to perhaps 1200 beds. A large number of beds would be required only for the first year or two, if the Act were effectually carried out, for, by the example of Malta, the forty or fifty beds occupied before the regulations were put in force, were reduced to one or two after the surveillance had been exercised a few months.

A third obstacle to the effectual working of the present Act is the limited number of towns that have been placed under its provisions. Constant changes take place amongst the troops of our garrison towns, and ships are as often passing from one port to another, and it is always found that with any arrival of troops or sailors from an unprotected town, in one that is under the protection of the Act, fresh disease breaks out, not only amongst the women but also necessarily amongst the men in garrison or in the harbour. Women also are constantly passing from one town to another, and following troops from one garrison to another; they likewise import new foci of disease.

Mr. Curgenven then turned to the good results derived from the Act. The army statistics for 1864 showed that of an average number of 73,000 troops stationed in the kingdom

there was a "loss of service by venereal diseases in the whole force, of nearly an entire week of that body's time.

During the year 1864, a total of 4385 cases of syphilis were under treatment in the royal navy, of which 1 died, and 101 were invalided. The daily loss of service from this disease was equal to 460 men.

The reduction of the amount of disease in the army by the operation of the Act although considerable is not as evident by statistics as in the naval and marine services. Among the troops in garrison at Plymouth and Devonport the number diseased was in April, 1865, 18 per 1000; September, 31; March, 1866, 28; September, 21; March, 1867, 13; September, 35.

These fluctuations in the amount of disease in the troops are due to the periodical arrival of regiments from unprotected garrisons bringing disease with them.

The marine division at Plymouth being a stationary corps, the beneficial operation of the Act in their case is very evident; the number of men diseased having fallen, with but slight fluctuations, from 24 per 1000 in April, 1865, to 12 per 1000, in October, 1867. In the navy, also, the numbers have diminished from 21 per 1000 in April, 1865, to 4 in October, 1867.

While the amount of disease among the naval and military population has diminished, a marked decrease has also taken place amongst the inhabitants of these towns. There is an absence of the severer forms of the disease, that formerly entailed acute suffering and death, the constitutional form which conveys the disease to the innocent wives and children has greatly diminished as seen by comparing the entries into Melville Hospital, Chatham, for the third quarter of 1864 with those of the corresponding quarter of 1867:—

1864	Syphilis	95	1867	Syphilis	45 cases.
——	Gonorrhœa	21	——	Gonorrhœa	33
	Total	116		Total	78

Many of the women who enter the hospitals do not return to the streets.

At the Royal Albert Hospital, Devonport, about one-third of those admitted are sent home to their friends or into refuges.

The obvious moral objection to the Act, that it removes one chief deterrent for the sin of fornication—viz., the fear of contagion, was greatly modified to the minds of the clergy present (at a meeting at Chatham) by the experience of the Rev. J. G. Baily, the chaplain of St. Bartholomew's Hospital, Chatham, who stated his conviction that the Act was the means of bringing under religious and moral instruction many scores of degraded women who had never been under such influence before; and that, during his chaplaincy of only ten months, no less than thirty-nine of these unfortunates had been restored to their homes, or induced to enter reformatory institutions.

One other benefit derived from the Act is that it prevents young girls, who are not depraved, from becoming prostitutes through the fear of surveillance and examination. It also tends to prevent soldiers' and sailors' wives living as prostitutes in the absence of their husbands, through fear of incarceration in hospital, and the consequent discovery of their evil lives.

Mr. Curgenven next recapitulated the labours of the society, of which he is one of the Honorary Secretaries, showing that with a view to open the subject for discussion and inquiry in England the Harveian Society of London, in February, 1867, appointed a committee to investigate the extent of the spread of venereal diseases among the population: "to discuss the best means of preventing that widely extended evil, and to report thereon to the International Congress in Paris."

This committee issued circulars to the surgeons of all the hospitals, and nearly all the dispensaries and infirmaries in the United Kingdom, and to all the workhouses in London, Manchester, and other large towns. By this means they gained a great amount of information as to the actual amount of venereal disease existing amongst the patients and applicants to these charities. The amount of the existing disease exceeded their anticipations. At St. Bartholomew's Hospital about one-half of the surgical out-patients' cases were venereal. At St. Guy's Hospital, out of 295 surgical cases, seen by Mr. Cooper Forster, 174 were venereal and 121 non-venereal. At the other hospitals in London the proportion ranged from one-fifth to three-eighths of the surgical out-patients. At the Eye and Skin Hospitals the proportion varied from one-eighth to one-fifth of the cases seen. At the Children's Hospitals the number amounted to one-fifth of the surgical cases. At Manchester and other large towns the amount of disease was about the same, averaging from one-eighth to one-third of the surgical cases. In addition to the great amount of venereal disease thus shown as being treated at the public charities, an equal if not greater number of cases come under the hands of chemists and quacks, to say nothing of those seen in the private practice of the profession. Thus the Committee at Manchester, co-operating with the Harveian Committee, in their reports say, "We are fully convinced that the quacks and chemists attend a large proportion of the entire number of venereal cases occurring in Manchester." The same is the case elsewhere, and there prevails in some places an extraordinary notion which prevents sufferers with this disease applying at the hospitals. Mr. Cardell, writing from Salisbury, says, "You will scarcely believe that there is a prevailing notion here (not only amongst the lowest orders) that if venereal patients got very bad in the hospital they were smothered."

The report of its committee was adopted by the Harveian Society in July, 1867, when a resolution was passed directing that a translation should be read before the Medical Congress of Paris by a deputation from the society. It was also determined that the evils revealed and remedial measures suggested, should be brought before the public, and the assistance of all those interested in the subject enlisted for the purpose of bringing the suggestions of the society within the sphere of practical legislation.

It was resolved:—

"That it is the opinion of the Society that an association be formed, to be called 'The Association for promoting the Extension of the Contagious Diseases Act of 1866 to the civil population;' that it should be composed of both lay and medical members, and that the gentlemen comprising 'the committee for the prevention of venereal diseases,' be asked to act as a provisional committee (with power to add to their number), for the purpose of organizing such an association."

This offspring of the Harveian Society has already been fully noticed in our columns. It numbers upwards of 500 members, and its objects are—

"To promote the extension of the 'Contagious Diseases Act' of 1866 to the Civil Population of the United Kingdom."

"To promote measures for increasing the amount of hospital accommodation for poor persons afflicted with contagious venereal diseases."

"To assist in every way the establishment of Refuges or Homes in connection with Lock Hospitals, for the purpose of receiving women who desire to leave their previous mode of life, and helping them to obtain respectable employment, or to emigrate."

MEDICAL SOCIETY OF LONDON.

March 30th, 1868.

Dr. Richardson, F.R.S., President, in the Chair.

Ten new Fellows were *elected*, and eleven candidates proposed.

ALOPECIA.

Mr. Hunt showed an example of complete recovery after alopecia. The patient, a steam-stoker, lost all the hair from the scalp at the age of 14. Mr. Hunt's treatment consisted in the internal administration of the chloride of arsenic and topical ablution with cold water; after treatment for 2½ years, there was complete recovery.

Mr. Rogers Harrison and Mr. Dunn, considered that recovery from alopecia occurred spontaneously or by the use of topical stimulants alone.

Dr. Chapman considered that arsenic in virtue of its tonic action upon the capillary circulation effected the same object as external stimuli.

Dr. Broadbent said that alopecia occurred quite independently of the course of nerves.

Dr. Tilbury Fox had seen equally good results follow the internal administration of dilute nitric acid. He considered the sporules, &c., of the fungus co-existing with alopecia to be very minute, and therefore frequently overlooked.

IODIDE OF METHYL.

The President exhibited a specimen of iodide of methyl, which he said was the most energetic of all known iodine compounds, and he thought promised to prove of the greatest use in practical medicine. The iodide was first experimented with

physiologically by himself, in the course of last year, and was reported on by him to the meeting of the British Association at Dundee. It is made by distilling wood spirit with iodine and phosphoros; it boils at 110° Faht. and its composition is CH_3I. It is a very heavy fluid, its specific gravity being 2199, its vapour density is 71. In the concentrated form the fluid is rather easily decomposed, free iodine being given off. Methyl can be administered by inhalation, and so given it produces general anæsthesia; but if it is undergoing change, the free iodine causes lachrymation, salivation, and excessive bronchial secretion; in an experiment, an animal died from the artificial bronchitis thus induced. The iodide of methyl can also be given by the mouth, one minim being equal to three grains of iodide of potassium; of all the iodides, it possesses the greatest activity of action on the body, it neutralises organic poisons and may be expected to be of service in tertiary syphilis specially. At his, the President's, request the iodide of methyl was now being tried in some cases of cancer at the Middlesex Hospital by Mr. Nunn, but sufficient time had not elapsed to report results. The facts, when sufficiently ascertained, would be brought before the society—the iodide of methyl also produced new compounds with some organic bodies, such as nicotine and other alkaloids and the author had endeavoured to make it applicable as an antidote. On this principle, iodide of methyl should be prescribed in a solution of mere mythylic alcohol.

The PRESIDENT concluded by referring to the antidotal effects of iodide of methyl on the alkaloidal bodies, such as strychnine; and to the substitution principle in therapeutical research.

NEW MODE OF TREATING THE CONJUNCTIVA.

Mr. SPENCER WATSON exhibited some discs composed of cocoa-nut butter, mixed with tannin and other astringents for ready application to the conjunctiva; passed beneath the upper eyelid, they melt, and diffused over the whole conjunctival surface, they possess many advantages over lotions; and cases of pannus with granular lid have been much benefitted by such treatment.

RUPTURE OF SPINAL CORD.

Mr. HENRY LEE showed a specimen of rupture of interior of spinal cord from concussion. Two cases in which the concussion had been induced by a fall upon the vertex had recently come under his care, in each there was complete sensory and moter paralysis, with diaphragmatic breathing. The seat of lesion was accurately diagnosed ante-mortem. Death occurred from apnœa. Such cases are sometimes related with the announcement that the cord had sustained no injury; this would have been said now, had the external portion alone been examined; it was only on longitudinal section of the spinal cord that the cause was apparent. A portion of the nervous substance was softened, and of a bright red colour.

Mr. HENRY SMITH brought forward a young girl, whose knee he had excised three months previously. The limb had been condemned to amputation, and the patient was in a state of extreme debility. Now this was a most useful limb, and the patient was in florid health.

ON SOME EXCEPTIONAL MODES OF THE TRANSMISSION OF SYPHILIS.

The paper of the evening was then read by Mr. VICTOR DE MERIC.

The author urged the value of etiological investigations that are easily undertaken in cases of communicable diseases. Though the history of the propagation of syphilis is generally well understood, there is yet much obscurity as regards some modes of its transmission, and especially as to the phenomena following contamination by secondary manifestations; moreover, at the outset it is difficult to understand why primary lesions affect certain parts of the generative organs, in preference to other parts equally exposed. The evidences of contamination are usually slight, so slight, sometimes, that we fail to discover them. The author related seven examples to illustrate his remarks, which are briefly as follow:—1. A lady, æt. 60, infected by her grand-child. 2. A gentleman of 40, covered with secondaries, no trace of primaries ever manifest. 3. Wife, æt. 23, communicating disease to husband by buccal symptoms, no affection having followed co-habitation. 4. Mucous tubercles on vulva of girl, psoriasis palmaria following, no initial symptoms. 5. Insidious secondaries in young girl, habitually watched and examined. no primaries. 6. Unexplained mucous signs in anal region of child. 7. Severe syphilis in a newly married lady, husband ever free from disease. Mr. De Méric concluded by stating that we should not (at once) attempt to explain exceptional cases by uncharitable surmises, but study the facts indicating unusual modes of transmission of which experience convinces us.

An animated discussion ensued, in which Mr. Bryant, Mr. Julius Levy, Mr. Dunn, Mr. Spencer Watson, and the President took part.

Mr. HENRY LEE advanced an important theory, to which observation had led him—that pregnancy seems to awaken a power of transmission in the dormant virus, as if the disease-germs, under such new condition, attained a higher vitality. The author replied, and in answer to Mr. Levy, stated his opinion, that the assumption of a urethral chancre was not a feasible explanation of doubtful cases, for such could scarcely exist without local symptoms leading to its discovery.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

WEDNESDAY, 18TH MARCH.

The President in the Chair.

PURPURIC MEASLES IN SYDNEY, N.S.W.

IN the absence of the Secretary, Dr. Atthill read a communication which had been received by Dr. Hayden from his friend Mr. Walter J. Carroll, L.R.C.S.I., of Sydney, New South Wales. The following is an abstract of that communication:—

Mr. Carroll had observed from the Medical Journals, that much controversy had arisen in Dublin relative to an epidemic which had been called purpuric fever, febris nigra, and by other names. He had observed an analogy to exist between the so-called febris nigra and a form of malignant measles which he had of late met with to a large extent in the course of his considerable private practice in Sydney. In the first five months of 1867, a most severe and general epidemic raged there. It commenced so mildly that of the first 250 cases treated by Mr. Carroll, none died. "Unfortunately (observes that gentleman) I soon met with a most malignant form of the disease. In this the eruption was always darker than it ought to be, sometimes purple or chocolate; and persistent often for eight or ten days, if the patient lived that time. In some cases of greater malignity, only a few dark spots, sometimes so few indeed as to escape notice, appeared on the face or thorax, while on the extremities three or four vesicles would form, which would appear in the morning, perhaps no larger than a flea-bite, and at noon would be so extended as to involve a surface equal to the disk of a stethoscope, at which size they would usually break, exposing a black or chocolate surface, gangrenous to the sight and smell." This, if the patient still survived, usually spread so as to lay bare and raw within twenty-four hours, almost the entire surface of the body. "In all forms (continued Mr. Carroll) the tendency to convulsions was most remarkable." The attack was frequently ushered in by them, and nearly every fatal case terminated by them. "Some cases, which undoubtedly gave evidence of ventricular effusion and spinal lesions, were remarkable for the duration of life, when complete paralysis of all voluntary muscles, and complete inability to eat or drink existed." Patients perfectly and hopelessly comatose have existed ten and twelve days on nutritive enemata. None of the resident practitioners, who all treated more or less of them, doubted their being measles; but Mr. Carroll's practice "being more among the middle and working-classes, and very much among the clubs," he saw and treated more cases than any other person in Sydney. His cases he computes at 900, and his loss by death at 6 per cent.

Contrary to the general law of epidemics, this came in mildly, and gradually became more severe and fatal, and so continued to the end. An aphthous condition of the mouth and intestinal canal was observed in many cases. Gangrene and complete sloughing of the cheeks occurred in some instances. Beside the marked tendency of the epidemic to induce cerebral and spinal complications, almost every case showed evidence of more or less spinal irritation. "Dysentery and diarrhœa were very prevalent, and often most intractable. Inflammation, simply of the large intestine, often demanded attention, when all other symptoms were light."

Mr. Carroll's treatment was most stimulating in all cases. "When the disease was severe (he observes) quinine and turpentine were freely given. Where irritation of the spinal canal was present I gave, night and morning, half a grain of calomel, besides, every two hours alternately, I gave two or three minims of spirit of turpentine, and an astringent antacid mix-

ture containing tincture of opium and trisnitrate of bismuth. Of the many modes I tried I found this the best. The calomel acted gently on the liver and improved the secretions. Brandy, port-wine, isinglass, and beef-tea, where permissible, were freely given.

"Some persons here used largely the bisulphites of soda. I cannot, however, speak freely of them, as my experience was limited to two fatal cases. Many do, however, praise them highly here. I have administered chlorate of potass. It was of service, but not equal to the turpentine. I sometimes thought that it had provoked that severe irritation of the bowels, which was sometimes diarrhœa and sometimes dysentery, and always hard to manage. To the rectified spirit of turpentine, given in an emulsion, with or without quinine in solution, my most marked recommendation is given. It surpasses all other stimulants, being most rapidly diffused, and maintains the circulation in the engorged capillaries of the lungs, the integuments, or the extremities. Under its use I have seen respiration improved, the eruption grow brighter, and the circulation increased, heat being generated. It is, therefore, indirectly if not directly, an oxygenizer of the blood. The dose which I have named above is a medium one for a child one and a-half years old."

When this paper had been read an interesting discussion ensued, in which several members took part; and a general desire was evinced to encourage communications of this kind, from their highly useful and practical tendency. A vote of thanks was given to Dr. Hayden for his kindness in bringing before the society Mr. Carroll's most interesting letter to him, and he was requested to communicate to that gentleman the views expressed during the discussion as to the utility and interest of the letter itself, and of similar communications.

Correspondence.

ORNAMENTING THE WALLS OF HOSPITAL WARDS WITH PICTURES AND PRINTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with pleasure in your last number a leading article on the ornamenting of the walls of hospital wards with pictures or prints, to vary the dull monotony of the view, and to present objects that might be productive of pleasure and instruction to the patients.

I also concur with you in your observations that in choosing Scripture extracts as the decorations of the walls of hospital wards it is difficult, if not impossible, to select such as would be applicable to all.

Many years ago I was desirous of introducing a cheap decoration for the walls of the wards of the Whitworth Hospital (one of the House of Industry Hospitals), and I can now recommend, after an experience of some years, the system I adopted in principle and practice.

I foresaw the inconveniences that might arise from leaving the selection of pictures and prints as decorations of the hospital walls to private benevolence, as charitable persons, however well intentioned, might send pictures or prints that would not be acceptable to all, and thus the governing body of the hospital would be placed in the unpleasant predicament of either refusing the kindly meant donation, or of placing in the wards, pictures or prints that they could not approve.

I wanted, therefore, a tribunal to decide upon such prints or pictures as might, without offence to any or all, be placed upon the walls of my wards, and, after much consideration, I selected a tribunal to select the prints for the decoration of the walls, and I am proud to say that the prints selected by that tribunal have not given offence to any, and have given satisfaction to all—patients, attendants, chaplains, and governors.

The tribunal I chose is the *Illustrated London News*, and the prints selected for the decoration of the hospital walls are the chromographs published two or three times a year in that journal.

Those chromographs are laudable as works of art, are pleasing to the eye from the brightness of colouring, and are always directed to the cultivation of good taste and kindly feeling.

Latterly I have been able to supplement these with similar contributions from the *Illustrated Melbourne News*.

Now for a word as to the mode of mounting them. It was, of course, an object to have them set up with as little expense as possible, and some of my pupils, desiring, with their usual kind feelings to the sick, to aid me, undertook to fix them on thin pasteboard backings, and then varnish them. This was done, but it was found that after some time the backings warped, and that the face of the prints became discoloured from the dust and air of the ward.

They are now set up, on the recommendation of Mr. Mullen, Steward of the Hospital, in very plain frames of narrow gilt beading, with plain glass in front. This framing protects the prints, gives a finish to them, and does not cost more than about two shillings for one of the large sized chromographs.

These chromographs are published, I think, two or three times a-year, and an abundance of them can, I am sure, be always obtained *gratis* for hospitals from purchasers and subscribers of the *Illustrated London* and *Australian News*, and thus, for an expense of one pound (the price of framing), ten prettily coloured and improving pictures can be obtained for a hospital ward.—Your's truly,

D. J. CORRIGAN.

Merrion-square, W., April 5, 1868.

JUVENILE SCRIBBLERS ON THE HEALTH OF EUROPEAN SOVEREIGNS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was delighted with your witty remarks upon the nonsense that has been for the last few months circulated by your so-called *medical* contemporaries, respecting the health of European sovereigns. Some of the juvenile scribblers for these journals would be delighted to be thought well-known courtiers, though every one knows when they do not invent their silly statements, they merely echo second-hand rumours set afloat by idlers *outside* club ranks. The pretence to fathom the secrets of the Vatican may be looked upon as the culminating point of this folly. Personal experience in Rome satisfies me that no reliance is to be placed upon the news circulated by those who are really cognizant of the facts. How then can a young doctor waiting for practice, and filling up the interval by writing paragraphs for a London medical newspaper, know anything about it? For him to sit in his back-parlour and pen a sketch of the health of the Pope savours of confidence in the ignorance of the reader that is positively ridiculous. Surely the force of folly "can no further go." As to the editors who insert such stuff for the sake of getting it quoted in the daily press—which is the only point aimed at—they are guilty of one of the most offensive forms of quackery, and I trust you will again favour them with some of your able sarcasms.—I am, &c.,

ROMANUS.

THE PROFESSORSHIP OF HYGIENE IN THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

THE election to this chair, vacant by the resignation of Dr. Mapother, Professor of Anatomy and Physiology, took place on Thursday last at three o'clock, at which hour the Vice-President and Council and a number of the Fellows of the College were present. The gentlemen whom we enumerated last week—Dr. C. F. Moore, Dr. Cameron, Dr. J. Little, and Dr. Hewitt—presented themselves as candidates, and their respective letters of application were read by the Secretary of the College at the table. The Vice-President then, in accordance with the bye-laws, called upon the Junior Fellow in the room to draw from the box the numbers of seven members of Council to act as electors. The gentlemen on whom the lot fell having been duly sworn, retired to consider the claims of the candidates, and, after a prolonged absence, returned, and the Vice-President declared Dr. Cameron duly elected.

The election was regarded with some interest, as two of the candidates, Dr. Cameron and Dr. Little, were not members of the College, while Dr. Moore was a Fellow, and Dr. Hewitt a Licentiate.

Dr. Cameron, who has been selected for the vacant Professorship, is Analyst to the City of Dublin Corporation, and a Chemist and Lecturer of attainments and position.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper *only*.

Owing to the pressure on our columns we are obliged to hold over several Letters and Communications.

The Medical Press & Circular.

FURTHER OBSERVATIONS ON CHRONIC HEART DISEASES.

By JOHN C. THOROWGOOD, M.D.,

ASSISTANT-PHYSICIAN TO HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK.

ON MITRAL CONSTRICTION.

RECENT medical observation and research has done much to facilitate the diagnosis of constrictive narrowing of the mitral orifice from mere mitral incompetency with regurgitation of blood back from the ventricle to the auricle.

Some may think it a matter of needless refinement to take pains to distinguish between these two morbid states of the mitral aperture, but this is not the case, inasmuch as useful therapeutical rules depend on the correctness of the diagnosis; hence, although the question is often one difficult of solution, it is one worthy of some time and attention on the part of the physician. We proceed to lay down what appear to be the best guides to the diagnosis of a constricted mitral aperture, and then to speak of the prognosis and treatment of these cases.

The onward passage of the blood from the left auricle into the ventricle through an orifice that is abnormally constricted and narrow is frequently attended with a murmur having certain characters which distinguish it from the murmur of mitral regurgitation.

The murmur of *mitral regurgitation* is distinctly systolic, it is loudest at, above, and rather to left of, the apex, beat, losing quickly in intensity and pitch on passing to the cardiac base. At the inferior angle of the left scapula, and beside the dorsal vertebrae, from the sixth to the ninth, the murmur is more or less clearly audible; as we should expect, remembering that this is a backward, not a direct, murmur, and is caused by blood flowing back from the ventricle into the auricle.

The murmur of *mitral constriction*, on the other hand, is a direct murmur, and occurs at the time when the ventricle is filling from the auricle, hence it is not systolic in rhythm, nor is it diastolic, as sometimes stated in books, but it is post-diastolic, or pre-systolic, and this last seems the better term, since in a well-marked case, this murmur is caught just before the systole, running up as it were to the first sound. When strongly developed, it may completely cover the second sound at the left apex, but it is not often loud enough to do this.

With respect to situation, this murmur is loudest at, to right of, and above the apex beat; it is very soon lost, passing upwards and towards the left, and is not audible at the inferior angle of the scapula.

When the murmur is uncomplicated with the murmur of mitral regurgitation, and it may occur where the mitral valve is quite competent, loudness of the second sound over the pulmonary artery is a sign that, according to Stroda, the case is one of narrowing of the mitral orifice, rather than of mere roughness of the surfaces.

Reduplication of the second sound at the base may be noted, and is due to want of synchronism between the actions of the two sides of the heart.

In character this murmur has been described by Dr. Flint, of New York, as "somewhat rough, resembling the sound produced by throwing the lips into vibration by the expired breath. When this character of sound is strongly marked I have called it a *blubbering* murmur. This character of sound I suppose to be due to the vibration of the curtains which compose the mitral valve. It is heard with its maximum of intensity around the apex of the heart. Often it is limited to a small space. It is propagated best in a direction from the apex, anteriorly towards the median line, not so well in an opposite direction. Sometimes it is so loud as to be heard over a considerable area. It is pre-systolic in rhythm, and I have three cases now under my care in the Bellevue Hospital presenting this murmur. Its presence denotes, with some exceptions, the existence of mitral obstructive lesions; but its absence is no proof that such lesions do not exist. It is present in only a certain portion of the cases in which obstructive lesions exist; and it is especially apt to be present in one variety of these lesions, viz.—when the mitral curtains become adherent at their sides, and form what is known as the button-hole contraction."[1]

Dr. Flint observes further, that this mitral direct (presystolic) murmur may be caused by aortic regurgitation, even when the mitral orifice is quite normal. He explains this by the fact that the aortic regurgitant current fills the ventricle just at the time when the mitral direct current is doing the same thing, the regurgitant aortic current by distending the ventricle approximates the curtains

1 For two excellent illustrations of the "button-hole" mitral orifice see Hughes Bennett's Principles of Medicine, page 582 of the 3rd Edition.

of the mitral valve, and then the incoming blood from the auricle throw these into vibration, and so causes the murmur.

I have not myself had opportunity to verify this observation of Dr. Flint's, but it appears to me of interest in reference to the occurrence of "tactile thrill" or "tremor" in connection with the murmur of mitral constriction. When the mitral murmur is caused in the way alluded to by Dr. Flint the probability is that the eddying together of the two currents (the aortic regurgitant and the mitral direct) in the ventricle would produce thrill felt by the hand applied in the usual way over the heart.

Those who, like Dr. Peacock and Dr. Sutton, have lately drawn attention to this mitral constrictive murmur recognize tactile thrill as a common, and yet by no means a constant, sign of this form of valvular disease, and to ascertain under what conditions this thrill does or does not occur, is a subject for further observation and inquiry.

The presystolic mitral murmur may exist by itself and with a perfectly competent mitral valve, but often it coexists with a mitral systolic regurgitant murmur; then its diagnosis by physical signs with any certainty is impossible.

The points most likely to guide us are to watch the rhythm of the murmur while the pulse is felt in the carotids by the finger; to examine for thrill over the ventricle, and to remember that the effect of the constrictive murmur is to diminish the amount of blood that passes into the left ventricle, so that the chief amount of action will be found on the right side of the heart, a significant fact pointed out by Dr. Peacock in the *Medical Times* 1867, p. 131.

With respect to the effect of a constricted mitral aperture on the general circulation it may be stated that they resemble in a measure those of mitral regurgitation.

The left auricle, having to act with extra power, becomes hypertrophied and thickened; at times a notably dull spot may be found at the left back opposite the fourth dorsal vertebra, where very marked tubular breathing is heard in consequence of the left bronchus being compressed by the enlarged auricle, and, in regurgitant disease, the murmur is distinct at the same spot.

The effect of regurgitant disease on the left auricle is to dilate and thin its walls, rather than to produce the thickening and hypertrophy, which constrictive disease causes.

Be the auricle thickened and hypertrophied, or be it dilated and thinned, the lungs are sure to suffer; dyspnœa, cough, with bloody expectoration, and in bad cases, pulmonary apoplexies, are the results, but they do not come on so fast in mitral constrictive disease as they are apt to do in regurgitant disease, nor yet does dropsy of the extremities so soon make its appearance. The pulse, in mitral constriction, is small but regular, the face pale rather than livid, and the appearances those that betoken an imperfect distribution of arterial blood over the system.

I now subjoin a few short notes of a case to illustrate the statements that have been made.

The case was marked down in my note-book as an instance of mitral constrictive disease in August last, and the patient is still under observation.

Eliza W., æt. 23, first seen August 5th, 1867. Been ill between five and six years since she had rheumatic fever. She now feels very weak, has cough, dyspnœa, palpitations, and frequent attacks of hæmoptysis. She looks pale, rather thin. Now and then has noticed very slight œdema of ankles; pulse 112, remarkably small, not hard, regular; chest well-formed, sounds well; breathing harsh at both sides, with rhonchal sounds over left; heart's impulse not extended, scarcely felt at xiphoid cartilage; at apex and to right of it a short murmur inaudible at base, and inferior angle of left scapula. This murmur seems to precede the first sound of the heart, and was noted in August as presystolic. Under the influence of tr. ferri., great amendment took place, and of late there has been no hæmoptysis.

In this case the symptoms dated from an attack of rheumatic fever five years previously; since which time the chief complaint was of great debility, with now and then hæmoptysis, the patient looked weak and anæmic, had no dropsy and no certain signs of phthisis, the pulse was very small and regular, and the interval before the ventricular systole was occupied (as I judged by several auscultations) by a murmur. The second sound over the aorta was weak, and the right heart did not seem to suffer much. Under the influence of steel much amendment took place.

From all these circumstances I judged the case to be one of narrowing of the mitral orifice, not to any great degree, for the presystolic interval was not unduly prolonged, as it is when the channel is very narrow, and the ventricle therefore long in filling, neither as yet was the right heart notably involved, hence it seemed a case that might be viewed, as the event proved, hopefully.

To conclude with a word on treatment. In cases of constricted mitral this should be pretty uniformly on the tonic plan. Good diet with moderate allowance of stimulants, and twice a day from 10 to 20 drops of tinctr. ferri in water after food. By such measures we give power to the left ventricle and enrich the blood. The iron may be changed now and then for quinine or bark, for a time, but I believe the best results will be obtained by a prolonged course of the chalybeate in small doses in simple form, and always administered soon after a meal.

Digitalis is not to be relied upon in cases of pure mitral constriction; it is, indeed, more likely to do harm than good, by enfeebling the power of the already poorly nourished left ventricle.

In mitral regurgitation, on the other hand, digitalis is invaluable for the relief it affords, while chalybeates very often embarrass the circulation, increase the regurgitation, cause hæmoptysis, and have therefore to be abandoned.

THE TREATMENT OF DELIRIUM TREMENS BY THE APPLICATION OF THE SPINAL ICE-BAG.

WITH SOME REMARKS ON THE THERAPEUTICAL VALUE OF CAPSICUM.

By D. B. HEWITT, B.A., L.K. & Q.C.P.I.,

ASSISTANT-PHYSICIAN TO THE CITY OF DUBLIN HOSPITAL.

(A paper read before the Medical Society of the College of Physicians of Ireland, April 13, 1868).

My object in bringing this case under the notice of the society is to elicit the experience of any who may have adopted a similar line of treatment, and to direct attention to a therapeutic agent not yet very generally adopted in this city. I distinctly repudiate any wish to draw any general conclusion from a single case, but I am anxious to have the question ventilated as it deserves.

James Mulholland, a strong muscular fellow, of about 45 years of age, was admitted into the City of Dublin Hospital, on the 25th February, 1868. He had served in the 45th regiment for a number of years, and since his retirement had kept a tavern. For the last twenty years he had led an intemperate life, but since he became a vintner he drank night and day for about six months, and had not ceased up to the time of his admission. At that time he was in a most excited state, and while in the hall of the hospital he shouted and kicked about in a most violent way. On being visited by me, he told me that he had taken a little too much, and then proceeded to talk to imaginary persons, and to order his wife to begone out of that. He assured me that he should get some grog, as he always coaxed his stomach in that way. He was perspiring freely; his face and eyes were congested; his tongue moist and coated with a creamy fur; his pulse was slow, full, but very compressible, and his hands were tremulous. He was ordered to have beef-tea and milk, *ad libitum*, and a bolus containing twenty grains of capsicum in ℥ss. of honey.

In about two hours he fell into a disturbed sleep, which was broken by dreams, and phantoms of dogs, horses, soldiers, and spiders; and at my evening visit I found him dozing, and comparatively free from excitement. He con-

tinued to sleep all through the night, and at the morning visit on the 26th told us that he had not slept so well for months, for that, during that time, he had never gone to bed unless when "three parts on the wind," and when the effects of the spirit had passed off he could not sleep. His pulse was 56, full, regular, and very compressible; there was some muscular tremor, especially in the tongue when protruded; his head felt hot to the hand; there was no gastric irritation, but he told us that we had cut open his belly. He had taken a liberal amount of milk and beef-tea.

In the evening he was still quiet, but talked in the same rapid unconnected way. The capsicum bolus was repeated.

About 1 A.M., on the 27th, he awoke and became very noisy and violent, insisted on getting out of bed, and walked down to the kitchen; his shouting disturbed the entire hospital.

On the 27th, at 11 A.M., I ordered him gr. xxx. of capsicum with honey, but it had no more effect than the preceding dose. The sweating and tremors were much aggravated, and he was loud in his complaints against his wife, for not having made preparation for some distinguished visitor, who, he said, was staying at his house. His thirst was excessive, but he never asked for whiskey.

On the 28th, he was worse, not having slept any. He was ordered one-twelfth of a grain of tartar emetic, and fifteen minims of tincture of opium every second hour.

In the evening he was seen by my colleagues Dr. Benson and Mr. Tufnell; he was talking in the same excited way, his head was hot, he was sweating profusely, his pulse was slow, full, and regular, he told Dr. Benson that I had opened him, but complained of no tenderness on pressure in the epigastrium. At Dr. Benson's suggestion I had his head brought over the side of the bed and a stream of water directed from a height of some feet, and the adoption of this measure was productive of temporary relief, but he soon became worse than ever. An enema of 40 minims of tincture of opium and 20 minims of tincture of belladonna in a little mucilage of starch was administered, but it had only temporary effect, for he became so violent that he frightened two male attendants to such a degree that they ran out of the ward and would not return without the resident Purser's student. During the night it was found necessary to restrain him by putting on the strait-waistcoat until some more experienced person could be obtained to watch him.

On the 29th I found him pale, tremulous, sweating, with a cold clammy skin, and great exhaustion marked on his face. I ordered the strait-waistcoat to be removed and found the pulse in the radial so rapid and indistinct that it could not be counted, it was 116 in the femoral. I gave him one pint of porter which he drank eagerly, and this had the effect of rendering the radial pulse more distinct, and reducing the femoral pulse to 108. I ordered him to be dressed and walked about in the yard for about twenty minutes, as suggested by Dr. Benson. He was supported between two men at whom he shouted every few minutes. He imagined that he was surrounded by gold and strove violently to prevent the attendants getting any of it. When put to bed he still continued to talk in the same way. I then applied the ice-bag from the 4th cervical down to the upper lumbar spines. In a very short time after its application he fell asleep and slept so soundly that it was left on for more than two hours, when he awoke, took some beef-tea, and then fell asleep once more. In the evening I found him *free from the slightest trace of sweating, the surface was of a uniformly good temperature, the pulse had lost all its feebleness, and had become again slow, full, and regular, the face had acquired its natural colour and expression, and the tremors had greatly diminished; he had slept well all through the day.*

From this period his recovery was complete, his appetite soon returned, and he was given a liberal diet, without any stimulant. He slept for the greater part of three days, during which the ice-bag was applied thrice daily; he always found it strengthen him, and he said it made him feel as fresh as ever. It was discontinued on the 3rd March, owing to its giving rise to such depression of the circulation, as to produce an intermission in the pulse. He was allowed to walk out in the open air for short periods each day, and although he staggered about a little on the first day, he soon recovered his muscular power.

On the 10th of March he was dismissed cured, and he has since been seen by Dr. Benson and myself, and has had no relapse.

And first, as to the use of capsicum in delirium tremens, I can state from my experience of its effects in three cases, that it is decidedly beneficial, and that there are many cases in which it will effect a cure without the use of any other remedy, still there are cases, of which the present is an example, where it will fail.

This remedy was introduced to the notice of the profession in Dublin by Dr. Lyons, and he has published some cases in which its use was most successful. These observations bear out the statement of Kinnear, of the Melville Royal Naval Hospital, who had extensive experience of the action of this drug.

I have administered it in doses of twenty to thirty grains, in half an ounce of honey, directing the patient to swallow it without chewing.

I have never found it produce vomiting or any tendency to epigastric tenderness, although I gave it every six or eight hours; on the contrary, I have found the tongue clean, the appetite improve, the tremors and delirium to vanish, and in some instances even sleep to follow from its administration.

As to its *modus operandi*, it furnishes an example of the want of accordance between the physiological action of a drug and its therapeutical effects which is most instructive. All experiments hitherto made on the action of capsicum, have resulted in representing its action as that of a local and general stimulant, but in no degree a narcotic. Yet, that its action in many cases of delirium tremens is primarily stimulant, and finally antispasmodic, and even sedative, I think can scarcely be doubted. Of course it may be urged that the action of the drug is to so effect the brain and nervous system as, by its physiologically stimulant action, to restore them to a condition compatible with sleep, but this is only saying, in other words, that its *therapeutic* action is narcotic.

I am happy to be able to quote so well-known an authority as Mr. Macnamara, on the action of capsicum in delirium tremens, and I trust he will give the society the benefit of his experience. I understand that in one case which came under his notice it worked a cure, when almost everything else had failed.

In this case it had a temporary good effect, sleep was induced the first day it was given, but the two doses which were subsequently administered, seemed rather to excite than to benefit. It is a remarkable fact that the craving for grog exhibited by my patient was quite dispelled by the capsicum, and if this be found a general effect, it will prove an additional argument for its use.

In the next place, the tartar emétic and opium entirely failed in my judgment, and rather seemed to aggravate than to improve the condition of my patient, and I think this combination has been found to act better in those cases where stimulants have been administered in conjunction with it.

Finally, I was led by reflection on the state of my patient to adopt the use of the spinal ice-bag, and it is well to bear in mind that at the time of its application, the man was in a much worse condition than on admission into hospital, its effects cannot, therefore, be set down as due to any natural tendency to cure.

As the subject may give rise to discussion, I think it may not be amiss to give a detailed account of Dr. Chapman's views in a series of categorical propositions:—

1st. The nervous power in the spinal cord and sympathetic ganglia is in direct proportion to the amount of blood contained in those centres.

2nd. That all secreting cells derive their nerve influence,

and consequently their functional power, from a branch of a spinal nerve, which he calls the positive motor nerve, but their functional activity may also be affected in a less degree by increasing or decreasing their supply of blood, as may be done through a branch of sympathetic—the negative-motor nerve.

3rd. All blood-vessels are supplied by branches of the sympathetic, which supply the so-called muscular fibres of the arteries.

4th. Hyperæmia of the cord is said to produce cramps, spasms, and convulsions of the voluntary muscles.

5th. Hyperæmia of the cord increases the activity of the glandular system through the so-called *positive motor* nerve.

6th. Hyperæmia of the sympathetic ganglia induces a maximum amount of nervous effluence, which will give rise to excessive contraction of the minute capillaries, and thus produce peripheral anæmia and a fall in temperature.

7th. That this hyperæmic state of the spinal cord can be induced by the application of heat along the spine. The effects are : to increase the activity of the glandular system ; to lessen the general circulation ; and in some cases to bring on spasm of the muscles.

8th. Anæmia of the cord checks secretion and diminishes spasm.

9th. Anæmia of the sympathetic ganglia gives rise to a dilated state of the capillaries, and a rise in temperature.

10th. Anæmia of the spinal cord and sympathetic ganglia is induced by cold applied along the spine.

Much of all this is purely theoretical, and Dr. Chapman has not furnished us with any direct experimental proof of his views, except in as far as he makes use of the experiments of Claude Bernard on the function of the sympathetic, and on the nervous supply of the salivary glands, and I confess that up to the commencement of this winter I was a decided sceptic as to the effects of ice or hot-water to the spine. Having, however, witnessed the good effects of the ice-bag in some cases of amenorrhœa under the care of my colleague, Dr. John H. Benson, I was induced to use it in this case for the following reasons :—

From Dahlström's experiments on dogs we know that alcohol gives rise to muscular spasms, and to distension of the capillaries of the nervous centres. This hyperæmic state is, therefore, likely to be the cause of the tremors, spasms, jactitation, &c., as well as the excessive sweating of delirium tremens, assuming Chapman's views to be sound.

The coldness of the surface, and its coincident paleness are, on the same hypothesis, probably due to a hyperæmic state of the sympathetic ganglia.

In my case, the tremors, the sweating, the coldness, and paleness of the surface of the body were well-marked at the time of the application of the ice-bag.

I think that it is a remarkable fact that in a short time after the application of the ice-bag in this case, the following phenomena were observed :—

1st. The induction of sleep.

2nd. The diminution, and finally the disappearance of the tremors.

3rd. The regulation of vascular action.

4th. The cessation of sweating.

5th. The production of a rise in temperature all over the body with a return of the natural colour to the face.

I am quite alive to the fact that the same result may not be attainable in every case, and that further investigation is needed as to the effects, both in this and other cases of the application of ice to the spine, nor do I believe that we need necessarily adopt Dr. Chapman's explanations because we use this therapeutic agent.

I think we should alike avoid extravagant laudation, and blind and unreasoning condemnation when speaking of this as well as every other therapeutic agent, and while I am satisfied that its merits are not all that some would have us think, I feel confident that there may be many cases in which the application of heat and cold along the spine will be productive of benefit, and I am thoroughly persuaded that they are by no means impotent agents. As doubt has been thrown upon the possibility of the application of the ice-bag giving rise to an increase in the temperature of the body, I have made some exact observation with the thermometer which I shall lay before you, but I must also remind you that it is perfectly possible that even a fall in temperature might be the result of the use of the ice-bag ; for if, from any cause, the spinal and sympathetic centres be anæmic, a further degree of anæmia would be induced by the remedy, and I have observed a fall in temperature in one case, where the autopsy exhibited white softening due to disease of the arteries and consequent deficiency in the supply of blood. The amount of diminution of temperature, as observed by one of Casella's instruments in the rectum, was three-fifths of a degree.

In a man suffering from chronic bronchitis the temperature, as taken in the axilla, was four-fifths of a degree higher after the ice-bag had been applied for one hour and forty minutes.

In this case also there was a considerable diminution in the amount of expectoration, and in the severity of the cough during the application of the ice, and it was remarked to me by the patient that he had only coughed twice during the three hours he was under treatment.

I would not, however, advocate the use of ice in chronic bronchitis, if there was much congestion of the bronchial tubes, as it is calculated to induce congestion.

I have used the ice-bag in a case of hemiplegia in which the fingers were strongly flexed, and the wrist bent in the arm, there were also tremors in the muscles of the sound side. In this case, the rigidity was removed and the patient recovered the use of her fingers sufficiently to enable her to hold a needle and sew. She had been under various forms of treatment previously without much benefit, and I was led to adopt the ice from some improvement which I found to follow from the use of Belladonna.

The following table represents the results of three observations made with one of Casella's maximum thermometers. The instrument in each case was placed in the axilla for ten minutes prior to the application of the ice, and again for ten minutes prior to its removal. The period of application of the ice was in each case one hour.

	Before ice.	After ice.	
1st observation	99·4	99·8	Rise of 2-5ths 1°.
2nd observation	98·6	99·2	Rise of 3-5ths 1°.
3rd observation	97·6	97·8	Rise of 1-5th 1°.

These observations were most carefully made by Mr. Richard Croly, one of the Purser's students resident at the hospital.

At a subsequent date, Mr. Finlay, the senior Purser's student, made another careful observation for me with the object of contrasting the effects on the sound and on the diseased side, and the result was extremely interesting.

The temperature of the sound side was 98·4 both before and at the termination of the observation. While the temperature of the paralysed side rose from 97·°8 to 98·°2, thus indicating a rise of two-fifths of a degree.

I have thus wandered from my case, in order to establish the fact that the application of the ice-bag in some persons at least, and under certain conditions of the system, may produce some of those effects which Dr. Chapman's theory attributes to it ; it will require a much larger number of experiments than this to establish his views, but as far as I have gone, they tend to confirm some of his statements.

I think the thanks of the profession are due to Dr. J. H. Benson, for directing attention to Dr. Chapman's views and affording us an opportunity of confirming or refuting them, and I wish to contribute my observations to this Society in the hope that some may be induced to give the ice-bag a trial when they meet with a case of delirium tremens.

I think that the most suitable cases for its use would be those in which there is profuse sweating, with a pale exhausted expression of the face, much tremor, and continued wakefulness.

ON INSURANCE CERTIFICATES.

By Sir D. J. CORRIGAN, Bart., M.D.,
PHYSICIAN TO THE QUEEN IN IRELAND.

(A Paper read before the Medical Society of the College of Physicians of Ireland, April 13, 1868.)

THE relations which exist between insurance companies and our profession may be classed under three heads. The first comprises those duties which are discharged by members of the profession who are medical referees to insurance companies.

The medical referee, as counsel and adviser for the company which depends on him to protect it from loss by bringing all his professional skill and knowledge to the examination of the life proposed for insurance, to reject the unsound, to pass the sound.

On this, the first head, I have little observation to make. The duties of the referee are clear. He is bound to use all his professional skill for those who have engaged his services. They have a right to expect that his examination shall be searching, and those proposing themselves for life insurance assent to the examination and submit to it with a full knowledge of its object and its consequences. This is a straightforward matter of business between the insuring and the insured, and it is not necessary to say more about it.

I now come to the second head or division, comprising the relations which insurance offices desire to maintain between them and members of the profession in reference to lives insured without the knowledge of those whose lives are proposed to be insured, of which I cannot speak in any other terms than of condemnation.

The cases I class under this head are those in which A, desiring to insure the life of B, goes privately to an insurance company, expresses his desire to effect an insurance on the life of B, without the knowledge of B, or he proposes to B to effect the insurance, and B declines to be a party to it, to subject himself to examination.

Under such circumstances the course pursued is this:—The insurance company finds out the name of the medical attendant of B, and addresses a private note to him requesting him to give the company all the information in his possession, all he knows of B, all the knowledge he has been able to acquire of B's state of health, of any disease B may have suffered from, and of his habits of life; in fact, to betray the confidence B has placed in him, and, keeping the matter secret from B, to give all this information to a third party, the insurance company. The following is a copy of the communication addressed by an insurance company to the medical adviser of a case such as above. I, of course, omit the name of the insurance company and of the person whose life it was proposed to insure without his knowledge:—

"[Private and Confidential.]

"London, 7th January, 1867, S.W.

"SIR,—Having occasion to effect an assurance on the life of Mr. , Dublin, who has at times, I believe, been under your professional care, I have to ask that you will favour me with all the information you can touching his general health and constitution, and his present prospects of longevity, without, however, troubling him in any way. On receiving your opinion as to his fitness for assurance, I shall have much pleasure in sending you the usual fee of one guinea.—I am, sir, your obedient servant,

"————————."

Insurance companies would not venture to make such communications if there were not members of the profession who would (thoughtlessly, it is hoped,) reply to such inquiries; but I trust it is only necessary to draw attention to the matter to make every member of the profession, however humble, resolve to respect his own honour and the trust reposed in him by no longer answering such communications. I think every member of the profession will agree with me in unqualified condemnation of permitting this relation between insurance companies and the profession to continue, and in omitting no opportunity of giving such public utterance to their opinion that insurance companies will not henceforth ever presume to address to members of the profession such communications.

Suppose the intending purchaser of a horse were to write privately to a veterinary surgeon in these terms, and I shall follow as closely as possible the wording of the insurance letter just read—

"[Private and Confidential.]

"SIR,—Having occasion to purchase the horse of A. B., and hearing that the horse has been shod in your establishment, and has at times, I believe, been under your professional care, I have to ask that you will favour me with all the information you can touching his general health and constitution, without, however, troubling his owner in any way, and, on receiving your opinion as to his fitness for purchase, I shall have much pleasure in sending you the usual fee of one guinea.—Yours, &c."

What would be the opinion pronounced upon the veterinary surgeon who would enter into such private correspondence and give information to one of two parties, without the knowledge of the party who placed trust in him? And if such a course would not be defensible in regard to the purchase of a horse, it surely would be less defensible in regard to the speculation on a life, and on the life of a fellow-man, who has placed trust in the honour, and has placed the secrets of his life and of his diseases in the keeping of his medical adviser, that that medical adviser should reveal to others the information he had thus acquired. I do not think it is possible to defend the medical adviser who would be guilty of such conduct. It might, perhaps, be thought that if the life of the person proposed to be insured were fit in every respect for insurance there might be no objection in stating it. I cannot take this view. I think it is wrong in principle for the medical attendant of any one to enter into private correspondence with a third party on the health or life of any one who has been under his care. And on the ground of expediency it would be equally wrong, for, were such a principle adopted, insurance companies would soon come to know that when an answer was not returned it would mean that the prospects of longevity were little, and thus the insurance directors would, indirectly by silence, get the information required. I have heard it also put forward as an excuse for what I cannot consider other than a betrayal of confidence, that B, the life to be insured, is obstinate—that A has been wronged by him in pecuniary matters, and that A is justified in desiring to insure B's life without his knowledge, and, in order to effect this object, communicates to the insurance directors the name of B's medical adviser, that they may obtain privately such information as will enable them, with a prospect of profit, to speculate on the life. The end cannot, however, justify the means. And even if A were quite right in seeking to insure the life of B, and the insurance company were quite justified in seeking for all the information they require, all that would not justify the medical adviser in violating the confidence reposed in him. Moreover, were such conduct justifiable on the part of the medical adviser on the ground that B, the life to be insured, had been acting wrongly towards A, it would be impossible for the medical adviser to discover if the allegation were true, to defend his conduct on this ground, for he could not know what party was in the wrong unless he heard the statements on both sides, and these he cannot hear, as his communication is to be kept "private" from one of the party, to say nothing of the fact that it might, and often does, puzzle a Lord Chancellor, with all the facts before him in a case, to know which of two sides is right or wrong, or, it may be, which is the more in the wrong. I hope very many will now agree with me in reference to this second head of the relations between insurance companies and members of the medical profession, that it ought to be no longer tolerated.

The third head includes the class of cases in which an insurance company with the full consent of the person proposing to have his life insured, sends a series of questions to the medical attendant of the insurers, requiring to be furnished with all particulars as to past or present ailments, state of health, hereditary predispositions, habits of living, in fact, requiring information on every particular, marking the communication "private and confidential," and promising to preserve the secrets of it inviolate.

The following, copied from such an insurance inquiry, is a fair sample of the queries usually forwarded to the medical adviser, and requested to be answered:—

MEDICAL REFERENCE.

Question 1.—Are you the usual attendant of Mr. , and how long have you been so?

Question 2.—How frequently have you been consulted by him, for what description of complaints, and at what periods?

Question 3.—When did you last see him, and what was his state of health at that time?

Question 4.—Do you believe him to be now in perfect health?

Question 5.—What is your opinion of his constitution and general state of health?

Question 6.—Are his habits of life temperate as to eating and drinking, and have they always been so?

Question 7.—Is he active or sedentary?

Question 8.—Has he ever experienced any injury from accident, and of what nature?

Question 9.—Is he subject or predisposed to insanity, pulmonary disease, or any other constitutional or hereditary disorder having a tendency to shorten life, or is he addicted to any habit having that tendency?

Question 10.—Do you consider him likely to live as long as any other healthy person of his present age, being years?

Question 11.—Is there any other circumstance or information respecting his past or present health, constitution, or habits of life within your knowledge or belief, with which the directors ought to be made acquainted?

I feel that at first sight the view that I take of the course which the medical adviser should take in such cases may be a surprise to some, and may not obtain the assent of others. The view that I take of the course which the medical adviser should take in reference to the relations existing between himself and his patient and the Insurance company under this third head is, that he should no more reply to such a communication than he should to the class of inquiries comprised under the second head. It is true it appears at first sight there is nothing morally wrong in principle on the part of the medical adviser in his revealing to an Insurance company what he knows of the past and present state of health, of the proposed insurer, when he does so with the permission of the insurer. But is the consent of the insurer given with a full knowledge of all circumstances—with a knowledge of all the medical adviser has learned in professional confidence from him as to his constitution of mind and body, of his predispositions, of his hereditary tendencies, of his habits and of his morals? So far, however, is this from being the case that in a number of instances the medical adviser has a knowledge of matters that he never mentioned to others or even in his professional interviews with his client, matters often that it would be cruel to repeat, and from any allusion to which much evils might arise. Take the ninth question in the list of queries I have given. "Is he subject or predisposed to insanity, pulmonary disease, or any other constitutional or hereditary disorder, having a tendency to shorten life, or is he addicted to any habit having that tendency?" The answer to that query in many instances, must be either evasion, untruth, or revelations that should for ever be concealed in the medical adviser's own breast. Take the first member of the sentence, "Is he predisposed to insanity?" Cases occur to us in which the seeds of insanity, the first deviations from soundness of mind begin to show themselves, and which we are able to extinguish with attention to the general health and with the aid of the patient's own reason. Surely these things that we withhold for his own good even from the patient himself we never could be justified in communicating to others. Yet we must either be guilty of evasion or untruth if we withhold what we know. I have known the fond mother conceal from her own child that she was dying of cancer, and lay it as an obligation on her medical adviser when on her deathbed that he should never reveal the nature of her disease in order that her child should not have the fear of hereditary taint before her.

The medical adviser would not be justified in revealing the nature of her illness, and he would not be an honest man, if in order to avoid that he answered untruly or had recourse to evasion. Assuredly, in such instances as I have adduced, the insurer would not authorise his medical adviser to answer the insurance queries if he were aware of all the medical adviser knew. His consent then, that the medical adviser is at liberty to reply to the inquiry from the insurance company is given in ignorance, and the medical adviser is, therefore, in my opinion, not justified in acting on it.

Query 2.—Is there any other circumstance or information respecting his past or present health, constitution, or habits of life within your knowledge or belief with which the directors ought to be acquainted.

Can any medical adviser answer that query fully and truly without, in most cases, committing a breach of confidence? I think he cannot. I might adduce numerous other instances, but I know it is unnecessary, as nearly all my friends around me can, I am sure, call up many such from their own stores of memory. The question now naturally comes, how ought the physician, as medical adviser, to act in regard to those cases which I have classed under the third head of relations between insurance companies and the profession, viz., those cases in which, with the sanction of the insurer himself, the insurance company requires a confidential or secret statement from the medical adviser. I think there is but one course to be followed by the medical adviser in order to preserve his own integrity, and the inviolability which he owes to his patient, and that is, to refuse in all instances to reply to such queries. Very early in my professional life I felt the greatest repugnance to answer insurance queries. I felt that I was often placed in this predicament, that to answer in a full and explicit manner would be prejudicial to my patient would be a breach of confidence, and on the other hand, that not to do so, would be evasion or untruth on my part, and at length, after long reflection, and many years ago, I formed the resolve which I have never broken, to decline giving any reply to Insurance office queries as to the health, constitution, or diseases of any one who had ever been under my care. It required a little firmness in the first few instances to carry out my determination from the pleading of the patients, and the reiterated request of Insurance companies conveyed through the patients themselves. At length an incident occurred that fixed my determination. I received a communication from an Insurance company, threatening that they would not insure a certain life unless I gave them the information required, that this would entail on the applicant's family the loss of the life assurance, and that they would view me as culpable and responsible for the results. This was too much to be borne, so I wrote to my client to express my belief that there was competition among Insurance offices and recommended him to go to another. The original Insurance office on this intimation took up his life assurance without any certificate, and I have had no trouble since.

Let the insurance office take the constitution of a man whose life they are about to insure in like manner as they would take the constitution of a horse they would desire to purchase. Let the insurer be examined by their own referee. It is their business to have a referee on whose perception or knowledge they can rely, but I hope the profession will no longer tolerate a system under which they may apply to the medical adviser of the insurer for information acquired in confidence in the course of professional intercourse. To sum up, I would submit to you these conclusions—1st. That, in reference to the first head, the medical referee of the insurance company is bound to make the closest scrutiny of every case submitted to him for examination, and to exert all his professional observation and knowledge for the protection of the company for whom he is acting; to see that the life is a fit one for insurance. 2nd. That as regards the second head, viz., when an insurance company asks for information as to the health, constitution, habits, or probability of life of any person from his medical adviser, concealing it from the life proposed to be insured, the medical adviser should not give it. 3rd. That even where the person applying for insurance authorises his medical adviser to communicate to an insurance company all that he knows of his (the insurer's) constitution, predispositions and diseases, the medical adviser should equally refuse it, inasmuch, as the consent of the insurer is given in ignorance of what may be revealed, and the information required to be revealed may be of such a nature as should not be communicated to any one, even in some instances to the insurer himself. I do not expect at once assent to my views. I may be wrong in some of them; but believing that they are worth consideration as a branch of the ethics of my profession, I have ventured to bring them before this meeting.

At the conclusion of the paper there was loud applause. A lengthened discussion followed.

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

CASES BEARING ON SOME OF THE POINTS TOUCHED UPON IN DR. R. MACDONNELL'S LECTURES ON SYPHILIS.

By CHARLES R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

Case 1.—Incubation of primary sore—Feb. 20, 1868.—H. B., 37, a clerk, had intercourse with a prostitute on December 10, 1867. In a few days after this, gonorrhœa appeared, with scalding, &c., and still continues.

January 6, 1868.—A hard knot and chancre appeared on prepuce; and, some days afterwards, multiple glands in groin. Incubation about a month in this case.

Case 2.—The wife of this patient came before with discolouration, of "café au lait" colour, at sides of the mouth, and hoarseness and spots of psoriasis on arms, on February 10, having been some weeks ill. Did not remember having had any primary affection. This is frequently the case

in women, and they constantly say that they have not suffered from any ulceration.

Case 3.—J. B., aged 27, employed in the Custom-House, 14th January, 1868. Pustular syphilide; enlarged inguinal glands. Connection with prostitute once in November, about the beginning of the month. Hard sore on penis about Christmas, 1867; eruption in January, 1868. Incubation 30 days.

Case 4.—T. Meyers, aged 30, seen June 4th, 1867. Patient had intercourse with a prostitute at Christmas, 1866, while his wife was near her confinement, and *two months* afterwards observed a hard sore on the penis. At present, June, 1867, has excavated ulcer of the tonsils, and scaly eruption.

In another case, seen about the same time, the incubation appeared to have been as long as three months.

Case 5.—John C., 50, shopkeeper, had once intercourse with a prostitute after his wife's death in July, 1866; *four weeks* after this he noticed a small sore on the penis, rather hard, and in August, or the beginning of September, a skin eruption appeared. At present, February 19, 1867, he has alopecia, sore throat, roseola, and a papular eruption on the abdomen, with headache and great weakness.

January, 1868.—The patient is now perfectly well, having been treated by means of small doses of chlorate of potash, as a placebo, in order to allow the eruption to gradually evolve the poison.

It will be noticed that the time of incubation in the above cases of the primary lesion is about four weeks on an average. It has been remarked by Dr. McDonnell in his last lecture (Medical Press and Circular, February 19th, 1868), that syphilis is an intoxication, like variola, and may in many cases get quite out of the system, like the other intoxications. He says, "When I see a patient with a hard chancre, accompanied by hard glands in the groin, followed by the usual syphilitic sore throat, pains in the bones, affections in the cervical lymphatic glands, several successive crops of syphilitic eruption on the skin; and when I see this patient getting well and married, his wife in good health, in good health himself, and the father of healthy children; when I know that from first to last he has not taken one grain of mercury; that he has been treated on the simplest principles of hygiene, how can I refuse to believe that there has been a poison which has been eliminated, and that health has been as perfectly re-established as after recovery from small-pox or typhus." The following cases will illustrate these admirable remarks:—

Case 5.—Charlotte D., age 16, seen at the Farringdon Dispensary August 2nd, 1863, with roseola, alopecia, and enlargement of the posterior cervical glands. Was treated by doses of chlorate of potash—thus, pot. chlor., gr. v., acidi. hydrochlorici, diluti m. v., aquæ menth, ℥j., t.d., for some months, until October of the same year when the roseola had disappeared, and she looked well. She was pregnant at the time.

Case 6.—Thomas P., afterwards husband of Charlotte D., age 20, came at Dr. D.'s request soon after the patient No. 5 was first seen. Posterior cervical glands enlarged, also gonorrhœa and a scaly eruption. Treated in the same way by means of a placebo, with chlorate of potash; he lost all his symptoms in two months. These patients married soon after this, and had a child born at full time, which lived seven weeks, and died of convulsions. On November 5th, 1865, Charlotte brought her second child to Dr. D., aged five months, without any symptoms of syphilis, and the same child has been seen by him recently, February, 1868, now being two and a-half years old and in good health. Both parents are at present free from all trace of syphilitic disease.

Case 6.—Charles C., a gentleman, in 1851 had syphilis, which was treated simply, and gradually vanished. Married twice, and by the second wife had three healthy children. No signs of syphilis in 1866.

Case 7.—Emma P., 24, with ulcers on soft palate, and roseola. Seen at the Farringdon Dispensary, Feb. 10th, 1864. Treated by chlorate of potash and gargles till April, 1864, when all symptoms being gone she left. Seen repeatedly since; but with no signs of syphilis observable. Seen last January, 1868, for toothache. No vestige of the syphilitic affection remaining.

Case 8.—Catherine C., age 24, April 25th, 1864, with stains of "café au lait" colour on face and breast, and spots of psoriasis on thighs. Was treated for this affection for four and a-half months at the Farringdon Dispensary by means of the following mixture:—Pot. chlor., gr. v., acidi hydrochlorici diluti. m. v., aq. menth. ℥j., t.d. The eruption, though more obstinate than in the last two cases, disappeared; the patient married, and was seen afterwards in 1866, in good health, and free from all appearance of syphilis.

In some cases, in women, the disease seems to consist almost entirely in a few mucous tubercles, and to affect the health but slightly.

Case 9.—Eliza M., 19, was treated from 19th May to 10th June, 1864, for slight sore throat and mucous tubercles of the vulva, which were touched with nitric acid and soon disappeared. The patient was seen frequently afterwards, and no return of the disease was remarked.

Case 10 was equally slight. Catherine H., age 20, 7th Nov., 1864; mucous tubercles of vulva and between toes. Touched with nitric acid. Observed for many months; no other symptoms made their appearance.

Case 10.—George W., age 18, iritis, roseola, and mucous tubercles on scrotum. Atropia drop (gr. ij. ad. ℥i.) dropped into the eye twice a day. The iritis soon disappeared, and the eruption and mucous tubercles, he having been under treatment from 27th March to 16th May, 1865. No further symptoms seen in 1867.

Case 11.—William T., 34, large mass of induration on prepuce. Roseola, mucous tubercles. Treated from 27th March to 14th May, 1865, by means of chlorate of potash mixture, and nitric acid to the tubercles. Seen in 1866 in perfect health.

Case 12.—Mary H., 26. Hoarseness, mucous tubercles on thighs and vulva. Treated by external applications from 27th March to 10th June, 1866; seen again in 1867, in perfect health.

Case 12A.—Eliza M., 27, slight roseola on arms, and sore throat; treated from 12th April to 18th June, 1866; very slight case. No other symptoms. Seen in 1867 without any symptom.

Case 13.—Kitty C., aged 23, indurated sore in umbilicus, hoarseness, alopecia, roseola. Treated from October 8 to November 20, 1866, with chlorate of potash mixture. She was pregnant, and in June, 1867, brought a child, which was suffering from snuffles and dry eruption on buttocks. The child recovered after taking a solution of chlorate of potash for a month. Mother well.

Such are a few illustrations of the remarks made by Dr. McDonnell.

Dr. C. Drysdale is now so convinced of the non-necessity of mercurial interference in cases of syphilitic eruption that he is certain that the practice will very soon be abandoned by all but routine practitioners. The only specific treatment he is in the habit of making use of is the iodide of potassium in cases of tertiary ulcerations of the lower extremities, fauces, or nostrils, &c. He then uses the drug in doses of from xx. to xxx. grains three times a-day in water, and usually with the most happy results. Tertiary symptoms of any severity rarely supervene after careful hygienic treatment of the eruptive stages of syphilis—perhaps not more than once in 20 cases, and are infinitely more intractable and severe when mercury has lowered the vitality, in Dr. Drysdale's opinion.

It is to be hoped that Dr. McDonnell's example may ere long be followed by many practitioners in London and elsewhere, who still adhere obstinately to the conviction that syphilis absolutely requires mercury, a belief which the above cases disproves.

CITY OF DUBLIN HOSPITAL.

CASE OF EXTENSIVE SUICIDAL WOUND OF THE THROAT.

Under the care of Mr. CROLY.

E. L., aged 45 years, who had been in a melancholy state of mind for some time, attempted self-destruction by cutting his throat with a razor; he was found by his friends lying in bed, bleeding profusely from a large wound on the throat; he was conveyed at once to the City of Dublin Hospital. Mr. Croly visited the patient immediately, and found him in an exhausted condition. His countenance was pallid and depressed; his voice was whispering; pulse feeble, and extremities cold; a fearful gash was observed on the front of the neck, through which the air escaped with a hissing sound. The wound gaped widely, and extended from about two inches above the origin of the left sterno-cleido mastoid muscle, in a curved direction upwards across the trachea, and terminated at the internal border of the right sterno-mastoid muscle, at a point corresponding to its centre; the wound was deep and traversed the thyroid body from below, and at the left side upwards and to the right, cutting its isthmus, and severing the two first rings of the trachea, the cricoid cartilage and the crico-thyroid membrane. Syncope supervening arrested the hæmorrhage temporarily. The patient was placed in bed, with warm applications to his feet, and took some wine; when reaction was established the bleeding recurred: three branches of the thyroid arteries were ligatured, and smaller vessels treated by torsion. The edges of the wound were retracted with tenaculums, in order to facilitate the ligaturing of the vessels; and the surface was frequently sponged to prevent the blood entering the windpipe. Venous blood flowed freely from the middle thyroid plexus, and threatened asphyxia; this hæmorrhage was arrested in the following manner: small pieces of lint, with strings attached, were passed down by a director on the front of the trachea through the bottom of the wound, due precaution having been taken to avoid pressure on the air-tube; the ends of the strings were fastened to the neck with strips of adhesive plaster. The patient at first offered some resistance, but subsequently submitted quietly to treatment. The weather having been cold, he was carried from the large accident ward ("the Martin") into the small "Purser ward" adjoining; a good fire was kept up, and a screen placed around his bed. The resident pupils (Mr. Browne and Mr. Finlay), who watched the case with the most praiseworthy care, kept the wound in the trachea clear of the viscid mucus, which collected in large quantities. Open vessels containing boiling water were placed in the ward to moisten the atmosphere, and a thermometer was kept at the head of the bed to mark the temperature. A flannel vest was put on the patient to protect the surface from cold; and besides the nurse, a male attendant was left in constant charge, to prevent him interfering with the wound, or otherwise injuring himself. The patient was turned on his side to favour the discharge of mucus; a piece of gauze, moistened with water, was placed over the wound, and the chin kept towards the sternum by means of a night-cap and a bandage. Beef-tea and milk were ordered, which the patient took freely, and ice was given to allay thirst.

Powders composed of calomel, opium, James' powder, and ipecacuanha, were directed to be taken at short intervals, to anticipate either laryngeal or bronchial inflammation. The plugs of lint were removed in a couple of days, and the wound was sponged with "Condy's fluid," and dressed with carbolic acid. The edges of the integument were approximated with strips of adhesive plaster, an aperture of sufficient size having been left in the centre, corresponding to the opening in the trachea, to allow the free discharge of mucus. The ligatures came away within a week. The wound healed by granulation, and the opening in the windpipe gradually contracted, and finally closed completely. The voice, which was at first whispering, became natural. The patient was taken home by his friends, and was subsequently removed to an asylum by Mr. Croly's advice, as he remained in the same gloomy state of mind, requiring close watching and special treatment.

Mr. Croly made some practical remarks to the pupils on this important case in the lecture theatre, as he could not do so, for obvious reasons, in the patient's hearing. He alluded to the exhausted condition of the man on admission into Hospital, the result of loss of blood and mental depression, and laid considerable stress on the necessity of securing, with promptitude, all bleeding vessels, and drew special attention to the manner in which the venous hæmorrhage was controlled. He next dwelt upon the mode of dealing with the wound, namely, by leaving it open until all oozing had ceased, in order to prevent the blood passing into the windpipe, or by infiltrating insidiously the tissues of the neck, thereby endangering life by suffocation. Mr. Croly also impressed upon the pupils the importance of attending to the temperature of the room in cases of wounds of the windpipe, whether suicidal or made by the surgeon, and alluded to the successful manner in which inflammation of the larynx, œdema of the glottis, and bronchial inflammation (the latter an almost invariable consequence of such injuries) were prevented in this case by such treatment. In conclusion, Mr. Croly demonstrated the mode of fixing the chin towards the sternum, by putting a night-cap on the patient, and fastening the strings to a bandage rolled around the chest, and explained the necessity of leaving an intelligent pupil in charge of such a case, to clear away the viscid mucus, as it accumulated in the wound, and also an attendant to prevent the patient displacing the appliances, or further attempting self-injury.

Should the patient refuse nourishment, or deglutition be prevented owing to injury of the œsophagus, the food must be introduced by a stomach tube passed through the mouth, or administered in the form of nutritive injections.

Literature.

OWEN'S CONSPECTUS.

THIS is a very unpretending book, but one that is likely to prove useful not only to students, but to every one engaged in medical or pharmaceutical work.

The best description we can give of it is the very full title-page, which accordingly we cite at length:—"OWEN'S CONSPECTUS; OR, STUDENT'S REMEMBRANCER: *showing in a tabular form, the Latin name (with its correct termination) of each article as in the* BRITISH PHARMACOPŒIA, 1867, *its English name, together with its synonyms, with a list of preparations into which it enters, and its proportion thereto; to which are added the* DOSE, OPERATION, AND USE; SPECIFIC GRAVITY AND CHEMICAL COMPOSITION." Articles now admitted to the Pharmacopœia, as well as those in which any change has taken place, either in name or composition, are clearly distinguished. Blank ruled pages have been interleaved, which render the work easily convertible either into a student's note-book, or druggist's private receipt-book.

Such is a description of Owen's Conspectus, published (by Messrs. Longmans) at the modest price of 2s. 6d. The author first compiled it as a cheap and simple book, for the first year's student in pharmacy. We are not at all surprised that he should have discovered from its sale that it will also suit many other persons. We have looked through it, with a view of testing its statements, in different places, and have in each case found them correct. We intend to let it lie upon our table to be handy for reference, and to serve as a small commonplace book respecting materia medica and pharmacy, for which its blank pages make it suitable.

VACCINATION.[1]

The offer of a prize for an essay on this subject by the Ladies' Sanitary Association, seems to have directed fresh attention to it, for we have just now a shoal of pamphlets of

1 Vaccination Impartially Reviewed. By Ferdinand E. Jencken, M.D. London: J. Churchill & Sons. 1868.

varying interest and merit, and about some of which we may be expected to say a few words.

Dr. Jencken professes to impartially review vaccination in a shilling pamphlet of 28 pages. He opens with a statement that "philosophers have ever been guilty of two grave errors," and having disposed of these he offers us the somewhat startling proposition that "there can be little doubt that we are possessed of two distinct organisms, accurately corresponding to each other in their minutest details—the one invisible, being immediately contiguous to the organic or vital power; and the other visible, subservient to the requirements of our earthly life." Dr. Jencken tells us further that "the former is permanent, and does not quit the spirit even when it has left its present tenement." He assigns it an "intermediate relation between the soul and the outward tangible organism." What it has to do with vaccination is not very clear, and so we shall pass on to the author's more practical views. He holds that there are minor reasons why vaccination sometimes is less efficient than others. Delicacy of constitution, hereditary taint, change of climate, variations in the virluence of the epidemic of small-pox, or in the power of the vaccine virus, all combine to modify results. Some individuals are also peculiarly sensitive to certain influences. Moreover, Dr. Jencken thinks "a sudden shock to the system, or an insurmountable dread of contagion, will often undo the salutary effect of vaccination, inducing an immediate attack of small-pox." This doctrine is not one that will find many defenders, and the mere appeal to "personal observation" will fail to satisfy most, that the occurrences were more than coincidences.

As to the dangers of the practice, it is admitted by the author that syphilis, and perhaps other poisons, may be conveyed with the vaccine virus, and that therefore the greatest care should be exercised in selecting lymph from healthy vesicles, and encouraging, as much as possible, the propagation of the cow-pock, by direct vaccination from child to child. He would also resort at times to a supply obtained from the cow.

With all the drawbacks he thus freely admits, Dr. Jencken recognizes the inestimable blessing bestowed upon mankind in the discovery of Jenner, and urges vaccination and *re*-vaccination, as safe preventives of small-pox, with its train of hideous and painful symptoms, to say nothing of its numerous fatal cases.

The next essay we shall mention is by Mr. Garlick,[1] for 20 years the Medical Officer and public vaccinator of the Halifax Union, and who promises, on the first page, that he "will endeavour to write what it behoves every parent thoroughly to understand." We may freely admit that Mr. Garlick has fulfilled his promise, and that, too, in a way which has afforded us amusement. He has attempted to give his essay a dramatic turn, for it takes the form of conversation between a mother and daughter. The young lady is not only very sensible, but highly sensitive, and much as we sympathize with her indignation at the infamous treatment of Poor-law doctors, we cannot deny that it is rather overdrawn. Few readers will admit the probability of a heroine becoming so excited by the tale of the parish doctor's grievances as to repudiate her name of Grace, ask to be called Alecto, Megæra, or Tissiphone, call for whisky to make a lotion to cool her fevered brow, and sink unconscious on the floor. Nor after such a scene is it natural that Grace, on her recovery, should recur to the subject with the exclamation—*Fiat justitia, ruat cælum.* Yet, as we have said the pamphlet has amused us, and it contains so much information, written with so much earnestness, that we can wish it a wide circulation. It is a pamphlet that may safely be placed in the hands of the public, and is more likely to be read than the majority of such productions. We shall be glad if Mr. Garlick finds the reward of his pains in the promotion of useful knowledge; still more glad if he tends to awaken a heartless public to a sense of its obligations to an ill-requited profession.

A third pamphlet on the same subject is from the pen of Dr. Godfrey,[2] of Enfield, and is a practical and forcible effort to show that "*bad* vaccination is better than *good* small-pox," while *good* vaccination is a perfect preventive. In spite of such solecisms as the above, the essay may be read with pleasure, and its wide distribution may exercise influence for good. Dr. Godfrey denies that vaccine may be a vehicle for syphilis or other diseases, and gives cases to which he has been called where such a charge was made, and which he proved to be unfounded. He holds that vaccine either conquers any other virus or dies, that it will not in any case mix with them or convey them, that as in presence of small-pox, one virus or other acts perfectly, and the other is destroyed. "The disinfectant destroys the poison when it comes in contact with it." The experiments of Cullerier, Taupin, Heim, Sigmund, and others, are cited in support of this view. In replying to objections he can be pungent too, as when alluding to those who are so fastidious that the idea of transferring morbid material from an animal to the human system is repugnant to them, he observes they are "silent when the diseased livers of animals have been deposited in their stomachs in the form of *Pâté de foie gras.*" Dr Godfrey believes, further, that vaccination is not impaired by lapse of time, but that its preservative power lasts through life. Still, like a practical man, he thinks re-vaccination proper, since, though if once thoroughly done, it will not take again, the second operation will be useful when from any cause the first was imperfect. We have other pamphlets to notice, but most postpone them to a future occasion.

1 An Essay on Vaccination. By Frederick Smith Garlick, M.R.C.S., &c. London: Simpkin and Co. Halifax: Nicholson and Sons. 1868.

2 Vaccination; its True Use and Power. By Benjamin Godfrey, M.D. Enfield: J. H. Myers. 1868.

CLIMATE OF WEST AFRICA.[1]

A work on the climate of the Western African colonies, commonly reputed the most deadly to be found anywhere in the British possessions, cannot fail to possess much interest; especially when we find that the author is himself a native of Sierra Leone, and commenced his meteorological inquiries there some fifteen years ago, so that he is now able to place before us the results of prolonged experience of the climate of West Africa from the Bight of Benin to Senegal.

The author proposes to divide the West African tropical year into three divisions in reference to its medical climatology.

1. The diarrhœal or dysenteric division.
2. The febrigenous or malarial division.
3. The congenital or pulmonic division.

The first division comprises the months of February, March, April, and parts of May, October, and November.

The second takes in May, June, end of August and September.

The third comprehends November, December, January, viz., the "Harmattan" months, a part of June, July and August. The cold dry Harmattan wind stops the manifestation of malarious fever on the system, but occasionally produces congestive fever by driving the blood from the surface to the interior of organs.

During the heavy rains it appears that the malarious beds are so inundated with water that they are for the time incapable of generating anything like malarial fever.

After a chapter replete with figures denoting a long and laborious course of meteorological observations during the years 1865-66, we are introduced to the subject of the effects of tropical heat on the system. The severe heat checks all attempt at prolonged intellectual work and interferes with the nutrition of the body; in males the virile powers are quickly exhausted, and in females the period of fecundity is very limited.

Dr. Horton insists strongly, p. 104, on the danger of cutting down trees, for malaria has an attraction for lofty umbrageous trees, so that a wind blowing over a swamp, and afterwards over a belt of lofty trees, will come pure and untainted to the town, while the cutting down of such a protective belt of trees has been proved to be a sure way of introducing malarious fever among a community.

Some readers may be surprised at finding Sierra Leone spoken of as one of the most healthy spots on the Western Coast of Africa (p. 82), but so it is; the one unhealthy spot appearing to be the city of Freetown, the capital and *entrepot* of trade.

The only breeze that comes pure and uncontaminated into the low lying city of Freetown is the N.W. wind which comes direct from the Atlantic, and yet, notwithstanding this, and other serious drawbacks to the salubrity of the city, the merchants persist in residing there although they might easily enjoy a pure atmosphere if they chose to betake themselves to villas on the adjoining hills.

The red soil of Freetown contains much iron and but little organic matter, because the effect of the iron is to decompose and destroy the organic matters existing in the soil. It is probably this process of decomposition of organic matter

1 Physical and Medical Climate and Meteorology of the West Coast of Africa, with valuable hints to Europeans for the preservation of health in the tropics. By James Africanus Horton, M.D., Edin.; Staff Assistant Surgeon of H.M. forces in West Africa. London: John Churchill and Sons.

induced by the iron of a ferruginous soil that has caused Sir Ranald Martin, and others, to condemn ferruginous soils as decidedly unhealthy, since the decomposing process of necessity evolves noxious miasms and vapours.

The practical summaries that are given by Dr. Horton of the rules for diet, clothing, and exercise, appear to us to be most valuable, They come from the experience of most competent men, and Dr. Horton has doubtless had opportunities of proving their trustworthiness in actual practice. As one example we may refer the reader to the precautions to be taken against an invasion of cholera as given at page 296 et seq.

All through the work we find evidence that Dr. Horton has read much, not only on climate, but also on other kindred matters; thus, we find him at page 231 giving his readers a short resumé of Dr Bence Jones' interesting researches on the presence of animal quinoidine in the body, and referring to Dr Symond's theory as to the true cause of what is called nervous headache.

These little matters, briefly touched upon, in our opinion tend to make the work all the more interesting and readable, even if they do add somewhat to the bulk of the volume, and there can be but little doubt that in Dr Horton's work we have not only a book pleasant to read, but also one containing much new and highly interesting information on the climatology of Western Africa.

GREENWICH HOSPITAL.

Another official report on Greenwich Hospital and Schools reminds us that some subjects seem to be inexhaustible. Yet we are free to confess that the labours of this new committee seem as unsatisfactory as those which have preceded them. It cannot be forgotten that Greenwich Hospital is no mere charity, but one of our most important national institutions, with revenues derived from the Crown and the Parliament. It is, therefore, of public importance that its management should be such as the nation can approve. Before 1763, there were scarcely any out-pensioners, but from that year these absorbed a large sum. In 1814, Parliament devoted a large sum to enable this service to be more completely carried out. In 1829 this was reversed, and Parliament undertook the provision of all out-door pensioners, leaving the hospital the duty of providing for in-pensioners, and an income for that purpose of £140,000.

Since 1848 the inmates have fallen off until the late change providing for those who preferred to live with their friends, and which has nearly emptied the buildings. At present the country has only 370 in-door pensioners, while there are no less than 15,000 out-door. Is it not time to revert to the ancient plan, and devote the revenue of the [hos]pital to out-door pensioners? If not, it is clear, beyond [doub]t, that the money is at the service of Parliament to devote as it deems best for the good of the country. It is incredible, but too true, that Greenwich is one of the costliest hospitals, although it is impossible that the medical department can occasion the outlay. Each bed in this national institution costs £94 a-year. At Netley the cost is only £76; at the Herbert Hospital it is only £61; at Woolwich £57; while the civil hospitals of the metropolis cost less still. Thus, the London Hospital, which may be taken as a medium, only costs £55 per bed, per annum.

Whence the waste? It is not the medical department but the civil which devours the nation's money, for no purpose but providing places for useless officials. The expense of the clerical element alone is such, that Parliament is not likely to suffer it to continue much longer.

If it is found the rule that men prefer to have their pensions and live with their friends, what shall we do with the buildings? Clearly, a large portion of them would be invaluable for a hospital proper or infirmary for the Navy and the mercantile marine.

The claim of the mercantile service on the hospital has been explained frequently enough in reference to the Seamen's Hospital Society, and it certainly does seem preposterous to spend money in new buildings while these are empty. The idea of a Naval Netley seems likely enough to be realized.

A correspondent has noticed an apparent inconsistency in our views in this matter. We, therefore, take this opportunity of explaining that, when we advocated the creation of a large naval medical school, we expressly proposed to sink in that the *Dreadnought*. That good service has been done by the supporters of the *Dreadnought* is on all hands admitted—that its claims are well founded few deny—that its staff deserve recognition is unquestionable. If we are to have a large hospital at all the fine pile of buildings on the river is ample, not only for the requirements of the navy, but for the commercial marine, and by union much better results must follow. In the organization of a school, naval medical officers would not be jealous of the services of the existing staff of the *Dreadnought* being retained. The civil element, in its turn, could not disagree with the naval, since its term would be temporary, probably lasting only for the lives of the present incumbents, after which the appointments would naturally fall into the hands of naval officers.

To attempt to create a great naval medical school without utilizing the staff of the *Dreadnought*, and without absorbing that institution into Greenwich, would be a wasteful blunder which could not fail to draw upon the department the eventual condemnation of the Parliament and the country.

REPRESENTATION OF THE SCOTCH UNIVERSITIES IN PARLIAMENT.

Ever since the proposal to give members to the Scottish Universities was made, we have consistently upheld the rights of these bodies, and urged their claims to even larger concessions than those that have been made. Our readers will remember that at the first we said that one member for each of the four universities would not be too much, and, looking at the representation enjoyed by Oxford, Cambridge, and Dublin, might fairly be asked for. The idea was in some quarters thought extravagant; in others it was supported in the same way that a general claim for more members for Scotland was put forward, but thought

as unlikely to be obtained as the additional fifteen asked for by some reformers for the Northern Kingdom. Still, in no influential quarter whatever was there any opposition to the proposal to grant representatives to the Universities of Scotland.

Further, our view that one member for each of the Universities would not be too much has been widely approved.

A statement issued by the Senatus Academicus of Edinburgh University shows how just is the proposal we put forward before the Scotch Reform Bill was framed. This statement compares the numbers educated at our Universities, as well as the number of Graduates. According to this authority, Oxford, with its immense revenues, only educates about 1700 students, while Edinburgh, with its much smaller resources, educates between 1500 and 1600.

Now, let us turn for a moment to the numbers of the members of these constituencies. Oxford has 4190 graduated members. Cambridge is a larger constituency, numbering 5354. Trinity College, Dublin, is much smaller—only 1877. Let it be remembered that each of the above constituencies returns two members to Parliament, and then we may see the claim of the proposed Scottish University constituencies by the following figures:—

St. Andrews and Edinburgh, which are conjointly to return one member, will number 5358—more than any other University constituency. Surely two members would only be just for these, if politicians could but suggest whence they are to be obtained. The joint constituency of Glasgow and Aberdeen Universities will number 2720 members, being upwards of 800 more than the number of the Dublin University constituency, which returns two members. We have no desire to see any of these institutions deprived of either of their members. Our wish is rather to see more University constituencies. We should have been glad to see two members instead of one conferred on the University of London, and we think four for the four Scotch Universities would have been more liberal and more just, as is abundantly proved by the figures we have quoted above.

Still, as so full a measure of justice is scarcely to be hoped for in the present condition of the question, we can have no hesitation in supporting the claims of Scotland to the instalment offered. The peculiar characteristics of the Scottish Universities are well-known, and that their members would be worthy electors has never been denied. We support, then, the conclusion of the body we have mentioned as *extremely moderate*. The senate submit that "Four Scottish Universities, which educate between 3000 and 4000 students annually, and send between 400 and 500 graduates into the professions of the kingdom, may justly and with much moderation claim two representatives when they find two allowed to Trinity College, Dublin, with one-third the number of students and one-half the number of graduates, and when their pupils amount to nearly the same as the united numbers in the two Universities of Oxford and Cambridge, which now send four members to Parliament."

THE MATERNITY DEPARTMENT OF SIR PATRICK DUN'S HOSPITAL, DUBLIN.

On the 6th inst. extraordinary prominence was given to the recent opening of a Maternity Department at Sir Patrick Dun's Hospital (Dublin), by the inaugural Clinical Lecture of Dr. Sinclair, King's Professor of Midwifery, under the provisions of the amended School of Physic Act of 1867.

The present position of the Obstetric Department of our profession, as compared with its status in Sir Patrick Dun's time, and for long after, is in itself highly significant.

About a century ago—and then Sir Patrick had been long dead—the practice of the Obstetric Art was considered altogether derogatory to the Profession of Physic—so much so, indeed, that the Fellows of the King and Queen's College of Physicians and the Board of Trinity College fell out because the latter body insisted that the degree of M.B. might fairly be granted to Mr. (afterwards Sir) Fielding Ould, whose name is well-known in connection with that great institution, the Dublin Lying-in Hospital. The idea of admitting any midwifery practitioner even a Licentiate of the Irish College of Physicians, had not then been openly expressed, much less advocated; and there can be little question that had any Fellow of that College proposed as a candidate for the Fellowship any Obstetrician, however eminent, he would have been quickly sent to Coventry by his brethren.

But if Sir Patrick Dun were now to rise for a while from under St. Michan's Church he would stare with amazement. He would not only see the Obstetrician so prominent in that College which he endowed, as that some two years ago the President, Vice-President, one Censor, Treasurer, Registrar, and two Examiners were all midwifery practitioners; but he would also behold in the hospital supported with his money a lecturer holding forth on the occasion of setting up the teaching of midwifery within its walls; and he would further observe that not only was that lecturer a distinguished Fellow of his own College, but that, by legal right, he styled himself "King's Professor of Midwifery on the foundation of Sir Patrick Dun."

But, in truth, this is only one of many proofs of the advancing spirit of our day, and of the rapid demolition of ancient landmarks.

We have only to repeat what we said before about this hospital—that, seeing that it can favourably compete with any other on scientific grounds, it ought not to be allowed to *compel* any class of students to resort to it for any time, long or short.

INSURANCE CERTIFICATES.

We publish in another column an important paper, which was read before the Medical Society of the College of Physicians of Ireland, on the 13th instant, by Sir Dominic Corrigan, Bart.

The subject being one of general interest, secured an unusually large attendance of the members, who listened with deep attention to the statements of so eminent a physician as Sir Dominic Corrigan.

The President of the College occupied the chair, and at the conclusion of the paper a discussion took place, of which we can only say, that it fairly established what we have often before heard stated—that the profession in Dublin might favourably compare with any other in the matter of eloquence and readiness in debate.

As we understand that this subject will be resumed in connection with a discussion on another paper, we need not here enter into it minutely, especially as Sir Dominic states his own views with an amount of clearness and precision which require no explanation from us. We must,

however, say, that we share in an opinion which seemed to be generally expressed in the discussion which followed the reading of his paper:—that his third position is untenable, or that at least it requires considerable modification. "The third head (he says) includes the class of cases in which an insurance company, *with the full consent of the person proposing to have his life insured*, sends a series of questions to the medical attendant of the insurers, requiring to be furnished with all particulars as to past or present ailments, state of health, hereditary predispositions, habits of living, in fact requiring information on every particular, marking the communication 'private and confidential,' and promising to preserve the secrets of it inviolate."

Every one conversant with the mode of examining lives for assurance knows very well that in numerous cases, perhaps in the majority, there is nothing whatever objectionable in the physician giving information, if requested to do so by his patient.

That cases, such as those sketched by Sir DOMINIC, will occasionally arise, wherein matters have been expressly concealed from the patient himself, for his own good, by the medical adviser, there can be no doubt. Yet we think these require exceptional treatment, and should not form the rule for the majority, concerning which there is no need for any secrecy, particularly when the good of the patient demands that there should not be any, and when he, himself, desires that there should not.

We fear that the ideal of perfection in medical officers of insurance companies started by Sir DOMINIC is not a practical one, so long as medicine remains an inexact science.

Notes on Current Topics.

The Public Health.

THE same favourable state of the mortuary records continues. In London the deaths in the last week were 238 less than the average of that week—the 15th of the year. The actual number of deaths registered was 1274. The annual rate of mortality for the week, for the large towns, was as follows:—London, 21 per 1000; Edinburgh, 28; Dublin, 22; Bristol, 31; Birmingham, 21; Liverpool, 25; Manchester, 26; Salford, 27; Sheffield, 22; Leeds, 21; Hull, 22; Newcastle-upon-Tyne, 23; Glasgow, 25. The deaths from zymotic diseases in London were 250, the corrected average for the week being 328. Of these 18 were due to small-pox; 49 to measles; 16 to scarlet fever; 8 to diphtheria; 50 to whooping-cough; 31 to fever; 10 to diarrhœa. Of diseases of the chest, we notice 168 deaths from phthisis, 143 from bronchitis, 79 from pneumonia, and 53 from diseases of the heart.

Health of Scotland.

THE month of March this year, in Scotland, has been remarkable for its high mean temperature, which was 44·2 deg., being 4·2 deg. above the average of the last twelve years, and higher than any year since 1859. This may in some degree account for the favourable returns which have been received. The deaths registered in the eight principal towns, viz.: Edinburgh, Glasgow, Dundee, Aberdeen, Paisley, Greenock, Leith, and Perth, during that month were 2409, which, allowing for increase of population, is 176 less than the average of the same month during the previous ten years.

"Forty-three per cent. of the deaths were of children under five years of age—the same proportion as in the entire year 1867. In Dundee, however, the ratio last month amounted to 53 per cent. The zymotic class of diseases proved fatal to 535 persons, constituting 22 per cent. of the mortality of the eight towns. This rate was exceeded in Dundee from the prevalence and fatality of measles, and in Greenock from that of whooping-cough. 110 deaths, or 4·5 per cent. of the total mortality, were caused by fevers. The highest mortality from that cause occurred at Dundee, where 6·1 per cent. of the deaths resulted from fever. Whooping-cough was the most fatal epidemic, having caused 155 deaths, or 6·4 per cent. of the mortality in the eight towns. The deaths from croup numbered 30; from consumption 341; from inflammatory affections of the respiratory organs 392. Diphtheria caused 22 deaths, diarrhœa 36, 66 deaths were ascribed to violent causes, 5 were suicides, 3 from intemperance, 11 from drowning, 31 from fractures. Four of the men and five of the women who died had reached the age of 90 and upwards; one woman was 99.

St. George's Hospital Museum.

WE have to chronicle the completion of the catalogue to the Museum of St. George's Hospital consisting of nearly 900 pages, and the publication of which may be considered an event in the history of pathology. The editors are Dr. J. W. Ogle and Mr. T. Holmes, and they have been assisted by Dr. Dickinson who succeeded them as curator. The work has been long on hand, having been interrupted by the death of Mr. Gray, and other unavoidable circumstances. The care with which it has at length been completed, will be evidenced by the index which occupies nearly forty pages in double columns. It appears to us that this catalogue is arranged in a very simple manner, and will, therefore, afford great assistance to any one desirous of studying Pathology. The whole of the valuable museum of St. George's Hospital is described so as to render it easy to study usefully that collection. Thus, each series of preparations is placed in a separate compartment, and the indexed catalogue of that series is also placed there. The student who wishes to investigate any simple subject has thus only to consult one series; while for more complex subjects it will only be necessary to look over two series. The editors deserve the best thanks of pathological students for the labour they have bestowed on this important volume.

Royal Polytechnic Institution.

OF the many scientific amusements that have rendered this institution so famous, none will be found more worthy of notice than the optical illusions that form part of the Easter programme. Founded on Faraday's experiments with cogged wheels they go far beyond them, inasmuch as they render it easy to demonstrate the laws by which they are governed to large audiences in a popular manner.

Aided by Mr. Pichler, Professor Pepper projects the large figures illustrating his lecture on a disc, and thus makes them visible to the whole audience. The entertainment is unique, and in the words of a late president of the College of Physicians, "Philosophy in sport made science in earnest."

Mr. Pepper's remarkable exposure of spirit-rapping and other spiritual manifestations is not likely to be forgotten, any more than his wonderful *ghost*; or we might dwell upon the newer and more perfect exemplifications of the principles upon which these entertainments were based now exhibited in the "manifestations *á la Home*," where everything is

seen floating in the air, or with the beautiful optical illustration of Anderson's exquisite tale of the "Angel and the flowers."

In a subsequent lecture there is also to be seen a capital *skeleton illusion* devised by Mr. Pepper and Mr. Tobin, which we commend to all young people as sure to amuse them, and to anatomists and physicists as worth looking at on a leisure day.

Medical Education.

THE oration of Mr. Teevan, published *in extenso* in our last issue, supports with considerable force, the conclusions we had expressed in our previous number respecting the curriculum, and ably seconds our appeal for a little more liberty for the student. We have no doubt that this as well as the many other topics touched upon by the orator, have been read with considerable interest; it is, therefore, unnecessary for us to further dwell upon them. We publish with pleasure, this week, a letter from Mr. Walter Rivington, called forth, apparently, by our criticisms on his able speech at the Medical Teachers' Association. The letter supplements the speech, and we are therefore glad to afford him space to accurately define his important suggestions. Whatever may be the result, we feel sure that free discussion of the whole subject of medical education is most desirable. We have spent, ourselves, much time and labour upon it, and we rejoice that at length there is a fair prospect of its exciting that degree of interest which is so pre-eminently due to a consideration of how the next generation shall be provided with men to carry on the noble work of scientific medicine.

A Medical Students' Athletic Club.

WE have much pleasure in stating that the United Hospitals Athletic Club started last year is in a satisfactory condition. It is found that the meeting of the students of all the hospitals once a-year for a day or two's sport exerts an influence not to be despised, and promotes that union which the size of London and the distance of its hospitals from each other so much discourage. Last year Sir Wm. Fergusson was president; this year Sir Thomas Watson has undertaken this part, and the vice-president's list includes a physician and surgeon from each of the hospitals. The meeting is fixed for the 5th and 6th of next June at Beaufort House, and we heartily wish it may prove a brilliant one. Any past or present student may become a member for the modest subscription of 2s. 6d., and we may hint that subscriptions from their seniors will be usefully employed by the students.

Laughing-Gas.

AT the Medical Society of London on the 13th inst., the properties of this gas were discussed, and some important statements made in reference to its revival as an anæsthetic. Dr. Richardson, the President of the Society, who, as is well-known, has devoted great attention to the subject of anæsthesia, related the history of the gas, and detailed his own experiments with it. These clearly showed that laughing-gas is not, properly speaking, an anæsthetic at all; but rather an asphyxiating agent. It has caused fatal consequences before, and Dr. Richardson felt it his duty to warn the members against the indiscriminate use of so dangerous a compound, which would be likely to be followed in a certain percentage of cases by lamentable accidents.

The sense of the Society seemed decidedly to support Dr. Richardson's views, and several members expressed their condemnation of the hasty manner in which the so-called new anæsthetic had been forced upon public notice.

The Ordeal of Battle.

WE commend to the attention of the Medical Council, who complain of insufficient powers to equalize the value of diplomas, the short cut pointed out in the case of Bryant *v.* Popham, at the London Bail Court last week. If an apothecary who falsely calls himself a surgeon can bring his qualification up to the level of his competitor by blackening the eye of an incautious disputant, there is hope that success in the reconciliation of contending factions may be achieved by a little less law and a little more vigour on the part of our medical legislators.

If the Medical Council really means to check diploma-selling, let it morally blacken the eye of the guilty licensing corporation, and we are quite sure it will be justified by the public as the pugilistic apothecary has been.

A Surgeon's Exploits.

WE are quite aware that we have many eminently skilled men in the profession whose services we are always ready to acknowledge; but we were hardly prepared to hear of the performance of such rapid and hazardous operations as we are here called upon to record. Mr. Boustead, Surgeon to the Abyssinian field-force, went out accompanied by two natives "to try and bag a lion," but as none were to be found, they proceeded to hunt for elephants. Five of these were soon discovered, two with large tusks, one with medium, and two with none. Mr. B. stalked the largest, and when within ten yards the elephant charged, but receiving a bullet in the forehead fell stone dead. The next largest he shot in the shoulder with a right and left barrel, and despatched him with a third bullet from his "little Mortimer," smashing the limb to atoms. A third old bull came on terrifying the natives, who, in their agitation, threw down Mr. B. with the butt of a spare rifle. He instantly sprang to his feet, and at five yards distant, calmly sent an "Enfield sized bullet" through the elephant's brain, which fell dead at two paces from him, and rolled over the precipice. Immediately a fourth elephant approached them, blowing and trumpeting hideously. At twenty-five paces, Mr. B. sent a heavy ball high in his head, and as he still advanced, another rather low which checked him; but again on he came, and the two cowardly natives ran up the rocks. Mr. B. made signs for them to throw him down a loaded rifle, he says—

"They chucked it down, and I caught it in the air as it fell, and gave the elephant a No. 12 through the shoulder, which disabled him. He tried to get up to the path where I was standing, but tumbled back, and in his rage commenced smashing to pieces everything in his way, making fearful noises. It was a rare sight to witness his wonderful strength; he bore down trees of considerable thickness by sheer strength and weight of body, and smashed their branches into thousands of atoms. Every bit of jungle was knocked to smithereens and trampled to pieces all around him, and his vain endeavours to get at us, and his terrible rage at being foiled, were really most exciting to witness. He nearly succeeded in getting up the incline to where I was, when I gave him the last bullet I had. His legs gave way, he staggered back on his hocks, and then rolled over heavily with a terrible groan. I can assure you I was thankful when it was all over and that I was out of the row so well."

Of the fifth monster, we hear nothing. He appears to have been too wise to face the fearful rifles, and so very quietly disappeared. If the army when it comes to the encounter makes as quick despatch with Theodore and his native forces as the intrepid surgeon did with the native brutes, we may soon expect to hear that the captives are released, and the expedition is on its way home.

Royal College of Surgeons of England.

In reply to the query contained in our remarks last week, on the coming election, Mr. Erasmus Wilson has addressed to us a letter, containing an explanation of his views respecting an association of the Fellows. We commend the letter, which is printed in our correspondence columns this week, to the attention of the constituency to which Mr. Wilson appeals, and we have no doubt that the frank manner in which he recognizes the right to question candidates, will gain him many supporters. It is clear that the day has passed when a man can expect to be elected to so important a post without a free declaration of his principles and intentions. We feel strongly on this point, and we urge all voters to refuse support to any candidate who does not pledge himself to a definite course. There are questions to be mooted which involve the welfare of the College, and, indeed, of the whole profession. These we shall examine on another occasion, and ask explicit declarations from the candidates. Meantime our columns are open to those who are ready to imitate Mr. Wilson's laudable and straightforward example.

F.R.S.

The Royal Society can hardly be said to have tarnished its prestige when it is in the position of announcing the names of fifty-three candidates for fifteen vacancies amongst its members.

The fact is sufficient proof that the distinction of an F.R.S. is worth having. We understand that twenty-three of the competing candidates are medical men, and we shall look with interest for the list of names that we may see how far scientific ardour outstrips monetary considerations in the contest.

Of the fifty-three claimants, probably one-half are of inevitable candidates who look for everything and get nothing, and who, by asking for that to which everybody but themselves know that they have no title, establish a *prima facie* case against themselves, and consign themselves eventually to the position of unavoidable bores. This class being eliminated, we have the candidates who, with some pretension to favourable consideration, seek for the position as a step to practice and an income. They cultivate science for what it sells for, and work it in the most remunerative direction for the same reason as they publish their compilations, because in the long run it "pays." These persons, having secured the alphabetical decoration have received all they wish for, and settle down into silent mediocrity as far as the pursuit of science goes. The deduction of this class from the list will leave a few—a very few—really earnest students, who work because they want to learn, and publish because they want to teach, and who seek for the F.R.S. as much for the facility of giving and receiving the co-operation of their brethren as for the honour and glory of the distinction.

These are the men, albeit they are usually the opposite of the "pushing" candidates, whom the Society should have, and it is to be earnestly hoped that all other claimants will be remorselessly weeded out, and space left in the scientific soil for the fruition of better material.

The Brown Bequest.

The Parliamentary contest last year between the Universities of London and Dublin, respecting the administration of the Brown bequest, will be in the recollection of our readers.

The testator had bequeathed more than £30,000 to the University of London for the purpose of establishing an infirmary for the diseases of the lower animals, with the proviso that, if after a certain period his bequest should not be carried out, the money was to pass to Trinity College, Dublin, for the endowment of a Professorship of Oriental languages. The University of London attempted, by passing a private bill through Parliament, to divert the money to other purposes, but were defeated by the University of Dublin.

They have now reverted to the original intention of the testator, and propose to apply the money to the foundation of a Professorship of Comparative Pathology and Medicine. Thus the endowment will be applied to the investigation of the highly important branch of science to which the cattle plague gave lately so forcible an impetus, and though it can hardly be supposed that the testator meditated this result in his demise, it appears to us that the application of the bequest to such a purpose is sufficiently near the original intention to allow of the scheme being carried out.

Poor-law Assistants in England.

The Boards of Guardians throughout England have received from the Poor-law Board an important communication in reference to the employment of unqualified assistants by their Medical Officers. The letter embodies an unequivocal condemnation of that practice, and calls upon the guardians to co-operate "in discouraging altogether the employment of unqualified assistants."

The letter continues as follows:—"The Board have no desire, however, to deprive the Medical Officers of the aid of legally-qualified assistants, and they therefore desire to point out that the Medical Officer may nominate his assistant, when duly qualified, to act as his substitute under the circumstances mentioned in article 200."

We anticipate that this decision, if it be rigidly enforced, will exercise very important influence on the demand for legal professional qualifications, and may prove to be the most radical reform of the present year in this direction. The action of the Poor-law Board is entirely justified in the public interest, inasmuch as a very large proportion of the Poor-law medical duty has been hitherto discharged by persons for whose competency no security whatever has existed. It is to be hoped that the enforcement of the rule will be followed by an increase of the salaries of English Poor-law Officers, to enable them to meet the increased expense.

It is, however, a remarkable consummation that the employment of substitutes for the discharge of ordinary duty is now officially approved and provided for in England; while in Ireland the dispensary doctor is not legally permitted to be absent from his district without special permission even for an hour, or to delegate his functions to another except in case of serious illness, and even then, unless he be alive to his own interests, he may be compelled to pay his substitute from his own

pocket. In point of fact, not only is the Irish Poor-law Medical Officer supposed to discharge the entire of the duties *propriis manibus*, but he is not even permitted the luxury of being sick without, in many cases, paying handsomely for the privilege.

A Royal Honour to Irish Surgery.

THE anticipation which we ventured to express, that the occasion of the Royal visit to Ireland may be availed of to do honour to the Surgical profession in Ireland, has, since the publication of our observations, gained strength in the minds and wishes of the profession in Ireland. The natural hope that the Surgeon to the Queen in Ireland might on such an occasion be made the recipient of a distinction intended for the Irish surgeons generally, has ripened into confident expectation that the Royal College of Surgeons in Ireland may, in being honoured by the presence of the Heir-Apparent, receive through the person of its President, the decoration which officially and individually he so well deserves.

We are convinced that the difference which has been made in respect of professional honour between England and Scotland and the sister island, and between medicine and surgery in Ireland itself, has been purely fortuitous, and it will be regretted by the entire profession if an apparent and unintentional slight be permitted to become a real cause for envy in the impression that Irish Surgery is not considered worthy of a single mark of honour to stand beside the five baronetcies conferred elsewhere. In the judgment of the profession, the Surgeon to her Majesty in Ireland, and President of the Royal College of Surgeons, is already Sir Robert Adams, and we venture to trust that our indication of his merits may not appear as an unnecessary dictation to those who have made apparent their earnest desire to act in every respect equally towards the country of which Mr. Adams is the most eminent surgical representative.

Presentation to Dr. Edward Hamilton, of Dublin.

ON the 4th inst., Mr. Hamilton, the Lecturer on Anatomy and Physiology in the School of Dr. Steevens' Hospital, Dublin, and Surgeon to the Hospital, was presented with a very handsome present of plate, and an address from his present and former pupils. The presentation, which was intended as a testimonial of respect on the occasion of Mr. Hamilton relinquishing private teaching, was handed to him in the presence of a very large assemblage of the subscribers and members of the profession. The address having been read, Dr. Grimshaw spoke in feeling terms of the regret which was experienced by the students of Dr. Steevens' Hospital in loosing Mr. Hamilton as their private teacher, and the gratitude which they experienced for the labour which he had uniformly bestowed on their professional education. The President of the College of Physicians occupied the second chair, and was addressed by Mr. Fleming, who, as consulting surgeon to the hospital, bore testimony to the worthiness of Mr. Hamilton to receive such expression of regard from the students of the hospital. Mr. Hamilton subsequently entertained his visitors on the occasion at supper.

WE inadvertently stated that Dr. Little, one of the candidates for the Chair of Hygiene at the Royal College of Surgeons in Ireland, was not a Licentiate of the College, which we were aware that he is.

The Queen's University in Ireland.

WE announced some time ago, that Dr. William Mac Cormac, Surgeon to the Belfast General Hospital, and son of Dr. Henry Mac Cormac, would be put in nomination for a seat on the Senate of the Queen's University in Ireland. On Tuesday, the 14th inst., the Convocation met at Dublin Castle, and Dr. W. Mac Cormac having been proposed by Dr. Mapother, and seconded by Mr. Ross, was duly elected. The new Senator occupies no less distinguished a position than the succession to the seat held by the Earl of Rosse, and he has been chosen by the Graduates of the University as their representative partly on account of the high position which he holds in Belfast where many of the Graduates have been educated, but principally because he contested on the part of the Queen's Colleges the power of the Senate to carry out the Supplemental Charter which, it was believed, would have greatly prejudiced the future of the provincial colleges, and because he succeeded in preventing the effort of the Senate to carry into effect the provisions of the new charter.

THE *Times* has opened its columns to a "Fellow of the College of Physicians," who is anxious to press upon public notice the danger of persons who have not recovered from scarlatina travelling in railways and other public vehicles. In reply to another correspondent, the "Fellow" further explains that the greatest danger is during the "peeling" stage before convalescence is complete.

AT the Medical Society of London, Mr. Mason lately exhibited an artificial hand, made by Mr. Pratt of Oxford-street, at the low price of three guineas, and which was so useful that, with a little practice, the patient could easily learn to write. We need scarcely say that nothing else at the price has been produced which will accomplish this.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.—MARCH 19TH.

IN HOW FAR IS TUBERCULAR CONSUMPTION TO BE CONSIDERED TO BE A CONTAGIOUS OR ZYMOTIC DISEASE.

A DEBATE was opened by Dr. CHARLES DRYSDALE on this question. After remarking on the extreme frequency of the disease, as evidenced by recent French statistics, which gave 160,000 as the annual number of deaths in France from consumption, Dr. Drysdale remarked on the hopelessness of the idea of curing the disease in the immense majority of cases, and in the present condition of our knowledge; and hence how important it would be if prevention were found to be more possible than it had hitherto been. It was as well to hear, whether or no we agreed with them, the arguments of those who, like M. Villemin, were sanguine as to much being done to prevent the ravages of that disease, which was certainly at present the great curse of the human race. M. Villemin, in common with Morgagni, Valsalva, Van Swieten, Morton, Hufeland, and other eminent authorities, believed in the zymotic nature of tuberculosis; and his arguments were well worth consideration. To begin with, the fact was now incontestibly proved, that grey granulations or yellow tubercle, or the sputum of persons affected with tubercular consumption, were all capable of producing tubercles in the intestines of some of the lower animals, when these were inoculated by those products. And although, of course, such experiments would never be made upon man, there was the greatest probability that such inoculations made upon human beings would lead to the evolution of tubercles in the lungs and death, and this too quite irrespective of the question, whether tubercle were precisely like the matter from variola, or not—*i.e*, a specific poison.

In the eyes of Villemin, hereditary transmission of consumption was an error of observation. That observer

only admitting hereditary debility, and accounting for the numerous deaths which so often occur in families by the members living together, and thus the healthy being contaminated by the sick. Villemin urges that, in hereditary syphilis the disease breaks out shortly after the birth of the infant; but in this, Dr. Drysdale observed, the learned author did not seem to be aware of the advantage his case might have derived from the facts observed by Mr. Hutchinson, that corneitis in the children of syphilitic parents might not appear until the age of 15, up till 30. As to the frequency with which consumptive patients referred to consumptive parents, Villemin accounts for this by observing that in large towns, such as Paris and London, among the poor operatives, from whom the statistics of hereditary are derived, the disease is excessively prevalent, so that one-third of those who die in hospital succumb to this dread disease. In the French army, where it appears that hereditary transmission is rarely assigned, since the troops are the offspring of healthy peasants, phthisis appears to be remarkably prevalent, and M. Villemin will have it, that the men infect each other in the barracks. Nothing, he says, is more heartrending than to observe in the practice of the military hospitals these robust peasants, with no hereditary transmission, and whom no excesses have injured, fall victims to the disease.

With regard to the influence of professions, nothing clear has been made out, since the chronic pneumonia caused by the inhalation of irritating substances is not to be confounded with tubercular consumption. Villemin's views as to the zymotic character of the disease are assisted by the fact that it seems to be very rare in Iceland, and in cold climates; and also at high elevations over the level of the sea. He quotes, in p. 336 of his work, Nicol, who states that at La Paz, a town of 40,000 inhabitants, in Bolivia, 3700 metres above the sea, consumption is not met with, although common on the sea-coast. The plague is unknown, also, above 600 metres, and the yellow fever and cholera prefers low lying districts. Tuberculosis is well-known to be far more prevalent in large towns than in rural districts. In the rural districts of England the mortality from the disease being 4 in 1000; and in Liverpool 6·40 in 1000 annually.

Prisons, convents and monastaries, are terribly visited by consumption, and barracks are well-known to be most dangerous in this way to the troops. No less than 9 in 1000 of the Cent Guardes in Paris, the chosen troops of France, succumb to this disease annually; and Villemin points to this as another evidence of the zymotic nature of the complaint. Troops on the march, on the contrary, are wonderfully free from consumption and, at Sebastopol, in 1854-55, among the allied armies, the complaint was almost unknown. The wandering Arabs are said to be very free from the disease, living as they do apart from all chance of contagion in tents.

It is alleged by various authors that consumption was unknown to some nations until their contact with Europeans. Livingstone asserts this of the tribes of Central Africa; and other authors say that the Indians of North America and the natives of the Pacific islands were first attacked with consumption, as well as variola and syphilis, when Europeans visited them. Apes are known to be, when confined in our menageries, perhaps even more prone to tuberculosis than man, and Villemin is so convinced of his thesis, that he accuses the breaths of the visitors to the Zoological Gardens of being the cause of this disease among the apes. Morgagni was greatly persuaded of the danger of opening the bodies of persons who had died of phthisis, and said "phthicorum cadavera fugi adolescens, fugio etiam senex;" and Laennec inoculated himself with tubercle when a student, and had unmistakable local appearances of tubercle at the spot. He died of the disease twenty years afterwards.

With regard to the unity of the disease, there are, no doubt, many forms and differences in the cases of phthisis observed, but not more than there are seen in the cases of typhoid fever or of syphilis, of glanders, or farcy. *Acute* consumption may kill in ten days; *chronic* consumption may last for twenty-five years; but usually it may be said that the disease runs its fatal course in adults in less than three years. And with regard to cases of fibroid consumption, they are probably not tubercular, and like chronic pneumonia of the grinders, not necessarily fatal. For a long time it was maintained, that glanders was not communicated from the horse to man, now it is universally admitted to be thus engendered. Glanders in the horse has much analogy with phthisis in man. In it are similar deposits in the lungs; it is fatal, engendered by crowding of horses into unhealthy stables, and hence probably zymotic disease. Glanders or farcy has also much analogy with syphilis in man, and many cases of the one have been mistaken for those of the other. But many persons assert, that glanders arises spontaneously in the horse. It may be so, but it is not found in horses which live apart and isolated; but among troop-horses and those which live in crowded and probably infected stables.

Tubercules are only, it appears, found among a limited number of zoological species. Glanders only attacks horses and men. Syphilis, scarlatina, measles, and variola only attack man. The cattle plague is peculiar to ruminants. Probably the cow, the ape, and some rodents have, alone, true tuberculosis, in addition to man. The so-called tubercles of other animals are merely parasitic lesions. The phthisis of cows, when inoculated on rabbits, is as certain to produce tubercles, as the grey granulative form in man. This result was obtained at the Veterinary College at Alfort, in France, by M. Villemin. It has often been asserted, that the inoculation of tubercular matter has nothing peculiar in it, and that *any* pathological product, almost, might, if inoculated, cause tubercles to appear. Villemin, however, asserts that he inoculated rabbits with pus from abscesses, &c., with cancer, and with the products of pneumonia, of typhoid fever, and all these with negative results. But subsequent experimenters have found that there are exceptions to this rule, and that some irritating species of matter will also excite tuberculosis in the rabbit.

No doubt appearances resembling tubercles may be obtained by injecting liquid mercury into the bronchi of animals; but the results are local, and the constitution is not infected, as in tuberculosis. Hence tuberculosis must, after this, surely be classed among the zymotic, or contagious diseases, to a certain extent, if we follow its analogies. Another point of analogy is one which obtains between phthisis and typhoid fever. Both are commonest from 20 to 35. Typhoid fever, too, is thought by many not to be contagious, and it is only in villages that the cases can be traced to contagion. Cholera is, in like manner, said not to be contagious by a great number of eminent men, *e.g.*, Greenhow. The poorer work people in Paris pass their lives in *garnis*, or furnished apartments; 40,000 men live in rooms containing eight to ten beds. This is the class in which consumption and cholera are found to rage.

In conclusion, Dr. Drysdale said that, although he was far from assenting to the views entertained by the enthusiastic discoverer of the inoculability of tuberculosis, he could not help saying, that his own experience, since his attention had been called to the subject during the last nine months, had tended to show that members of a family, especially husbands or wives, frequently became attacked post, if not propter, the death of their relations from phthisis. Would it not be erring on the safe side, he asked, to advise those, who were suffering from consumption, to sleep alone, and to have their apartments well ventilated. Is it necessary to admit persons with bronchitis and other diseases of the chest into hospitals for consumption, any more than into Lock Hospitals. He admitted and contended that consumption usually arose spontaneously, but this was no proof that it was not, in some cases, communicable, and there is no need that the imbecile prejudices which are opposed to the arrest of the spread of syphilis, should act in the case of a more dreadful disease such as phthisis. Lévry, in his treatise on Hygiene, t. ij., p. 763, says it is a certain fact that the examples of contagion adduced by authors, have principally existed between husbands and wives, and although we may invoke coincidences, it is difficult to withstand the idea of contagion, when we see robust women or men attacked soon after the death of their partners. Wives appear more frequently to be attacked than husbands, and, according to Gueneau de Mussy and others, this may arise from the contamination from the fœtus. It would also seem to be advisable for persons born with a tendency to consumption, if possible, to live in mountainous districts, and far from the fashionable resorts of the consumptive, such as the South of France or Madeira, as long at least as they remain free from the disease; when hectic and emaciation have advanced, of course, a mild climate may be a palliative and prevent suffering.

Dr. GREENHOW considered that the hereditary nature of phthisis was just as much proved as that of gout.

Dr. POLLOCK said that the inoculability of tubercles was the only feature it had in common with the zymotic diseases; there was no proof of its transmissibility by ordinary contagion.

Mr. ERASMUS WILSON looked with considerable doubt upon all the new views as to the contagiousness of different diseases.

Dr. BURDON SANDERSON said that the zymotic nature of tubercle was one of those irrepressible weeds which had continually arisen in the minds of pathologists, and which would always be reproduced from time to time. Recent experiments had led to the discovery that a very numerous variety of other substances besides tubercle, in fact, almost any pulverulent substance in a sufficiently divided state would lead, when inoculated, to the production of tubercular deposits in all the organs. But it did not necessarily follow that this disease was identical with phthisis in man. We must go back to clinical experience for an explanation of the causes and origin of phthisis.

After observations by Mr. Weeden Cooke, Mr. Curgenven, and Dr. Wynn Williams, Dr. Drysdale briefly replied.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

THE first session of 1868 was held at the Rooms of the Medical Society of London, on the 8th inst. Nearly sixty members were present. The President, Dr. Richardson, was in the chair.

Ninety-nine new members, seven associates, and sixteen honorary members were elected.

The HONORARY SECRETARY read a report on the proceedings which had been taken in regard to the Parliamentary and the University franchise.

Dr. GREENHALGH brought before the notice of the Association the recent action of the General Council of the University of St. Andrews. It appears that this body, consisting of 368 members, held their half-yearly meeting lately, when twenty-three of their number attended, and resolved to petition Parliament against the admission of the M.D.'s to the General Council. He protested very strongly against the tone of the remarks of some of the speakers, and proposed that some action should be taken in opposition to this move on the part of the General Council.

Drs. Crisp, Drysdale, O'Connor, Cleveland, Prosser James, and the President, took part in the discussion which followed, as to the best means to be adopted in regard to this matter.

Dr. CHOLMELEY proposed, "That the Honorary Secretary be directed to draw up a statement, showing the grounds on which the Doctors of Medicine claim a right to be placed on the General Council of the University, and refuting the arguments raised against their admission: And that he be also directed to forward such statement to the governing bodies of the University, with an expression of the deep regret of this Association at the determination of the General Council to oppose the claim of the Doctors of Medicine, and of the hope that this opposition will not be persevered in."

This resolution was seconded by Dr. Ross, and carried unanimously.

The PRESIDENT brought forward the subject of the registration of disease. He recounted the previous attempts at the accomplishment of this most desirable object, some of which had met with no inconsiderable, although but temporary, success. After reminding the members of the importance of the subject, and of the valuable results which would arise from a knowledge of the earliest appearance of an epidemic, or its persistency in one locality, and this measured not by its fatality, but by its existence, he briefly described his plan. He said that a very simple alteration in the forms sent in to the guardians of the poor every week by the Union Medical Officers, would provide the material needed. He proposed that these returns, having served their local purpose, should be sent weekly to the Registrar-General's office, and their classified and arranged for publication. The meteorological reports could be appended in brief, and a scheme of the Registration of Disease, such as was yet in existence in no country, could be obtained. He added that his proposals would entail no additional labour on the already hard-worked Poor-law Medical Officers.

Dr. CHOLMELEY proposed—"That the Earl of Devon, President of the Poor-law Board, be requested to receive the President and other members of the Association as a deputation on this matter."

Dr. ROYSTON seconded the resolution, and it was carried unanimously.

The very hearty thanks of the association were offered to the medical journals for the efficient support they had given to the association in its attempts to vindicate the rights of the Doctors of Medicine of St. Andrews.

It was arranged that the next session of the associatio should be held in the autumn, at Hempstead, in Essex, the place of Harvey's burial.

At the close of the meeting Dr. ROYSTON said:—Mr. President, before we separate I wish to ask you a question of some importance. I, and I believe all the graduates, have been canvassed for our votes by two competitors for the representation of the University in Parliament. I want to know whether the association has yet indicated any predilection on this point, and whether it is right for any of us to pledge himself to the support of any candidate.

The PRESIDENT replied—The council of the association has not as yet even considered the claims of rival candidates, and I should hope it will do nothing whatever on the subject until the Bill has passed, and the vote is an actual possession. To secure that end is the present work of the association, and when the position is certain it will be time to use it, not before. Then, in my opinion, it will be expedient to call a General Session, at which the merits of the several candidates can be discussed, and the most approved name submitted to the association for its unanimous support.

Correspondence.

MEDICAL TEACHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some of the criticisms which have been passed on the proposals which I made at the Medical Teachers' Association, were based on the supposition that I expressed myself in favour of establishing a Central Institution for Lectures, after the Parisian model. This supposition is erroneous. Whatever the womb of time may produce when the Schools have become accustomed to united action, I should have deemed it premature to bring forward such a plan. What I advocated was that Botany, Elementary Chemistry, and Comparative Anatomy, should be removed from the list of subjects taught at the medical schools, and that the two former at least should be required as preliminary subjects. In order to anticipate any objection that might have been urged on the ground that there would be no provision for teaching these subjects, I very briefly indicated that lectures could be given on them annually, at some Central Institution in the Metropolis. In the case of Comparative Anatomy I specified the College of Surgeons, on account of the Hunterian Museum; for Botanical and Chemical instruction appliances exist, as you remark, in greater abundance elsewhere.

Attendance on these courses would not be compulsory, but voluntary, and admission would be obtained by the payment of a fee. And I have not the slightest doubt that if such courses were of a first-class character, the attendance would render them amply remunerative.

Students not residing in or near the metropolis might find private tuition, if unable to acquire the subjects for themselves. But one result which would spring from the scientific subjects being required at a preliminary examination, would be that Botany, Chemistry, and Zoology, would be more generally introduced as a means of education, and instruction in them would ere long be provided in all our larger schools. This would materially contribute to raise natural science in this country to its proper rank.

The transference of Botany, Elementary Chemistry, and Comparative Anatomy, would in no way alter the existing relations of the medical schools. Not that a change in these relations might not be advantageously effected, but that there seemed so many obstacles to progress in this direction, that I did not touch upon the subject. All that I dealt with was the first stage of the medical curriculum, which offered a fair field for the early and effectual action of the Medical Teachers' Association. In some sense I must confess myself disappointed that the report of the Council will, in all probability, not appear till next November. But I look forward with some confidence to an endorsement of my views as to Botany and Elementary Chemistry, and as to the advisability of freeing students from the necessity of attending two courses of lectures on the same subject, and as to the inutility of requiring attendance during the first eighteen months on medical and surgical practice, and lectures on Surgery and Medicine. In any case these proposals are but a first instalment of my views on the very wide and very important subject of educational reform.—I am, sir, your obedient servant,

WALTER RIVINGTON.

22, Finsbury-square, E.C., April 8, 1868.

THE ENGLISH POOR-LAW.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should feel obliged if you will insert the enclosed communication in your journal for this week.—I am, sir, yours obediently, JOSEPH ROGERS.

"TO THE LONDON AND PROVINCIAL POOR-LAW MEDICAL OFFICERS.

"GENTLEMEN,—It is decided to call a public meeting of London and Provincial Poor-law Medical Officers towards the end of May or early in June, the day and hour hereafter to be determined, though for the convenience of country medical officers mid-day will probably be selected.

"The time is specially opportune. We are about to see the dissolution of the existing, and the election of another, Parliament on a more Liberal basis. The question of the better treatment of the sick poor both in London and the country has taken deep hold of the public mind, and it is desirable that Poor-law Medical Officers should assemble and express their opinion as to the best mode in which this question should be dealt with. This is the more requisite, as past experience conclusively shows that there is no probability whatever of any change, beneficial alike to the interests of the Poor-law Medical service and the sick poor, being ever conceded *(the negation of justice being solely dependent on your want of unanimity)*. It is, therefore, incumbent on all Poor-law Medical Officers to exert their influence in the forthcoming election, so as to secure pledges from candidates that, if returned, they will vote for such amendment of the law which, whilst securing more equitable consideration of their claims as Medical Officers, will enable them more thoroughly to perform their duty to the sick and suffering poor.

"If you have any suggestions, &c., to offer, please address them, gentlemen, to, yours obediently,

"JOSEPH ROGERS.

"33, Dean-street, Soho, W., April 13, 1868."

"12, Royal-terrace, Weymouth.

"DEAR SIR,—I have learnt through a friend, that you have it in contemplation to convene, at an early period, a public meeting of London and Provincial Poor-law Medical Officers, with the view of pressing on the Legislature the absolute necessity, in the interest of the sick poor and their medical attendants, of some very considerable modifications of existing arrangements. I am also told that you require money for the necessary expenses, I therefore enclose you a cheque for £20 from the fund belonging to the Poor-law Medical Reform Association.

"The movement has my hearty sympathy, and I regret that, although very much better, I am still unable to take any active part in Poor-law matters.

"Trusting you will have a successful meeting.—I am, dear sir, yours very sincerely, RICHARD GRIFFIN.

"Joseph Rogers, Esq., M.D."

THE ENGLISH POOR-LAW BOARD AND THEIR MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was extremely pleased when I read your leader of yesterday on the new regulations for English Poor-law Medical Officers. It is perfectly correct, and, alas, not in the least overdrawn, when it shows to the members of the medical profession who are fortunate enough to be able to dispense with union appointments, what a sorrowing, hardworking health-destroying, and degrading life must be that of the truly conscientious parish doctor. I say degrading, though only as it is applied to the accepted fee for work done, not for the work itself—that is noble, most noble, save that of the Christian ministry—that mortal man can be engaged in. It reflects the greatest honour on those who do such work for such pay, the greatest dishonour on those who compel medical men thus to slave and toil—surely they must forget the Divine words, "The labourer is worthy of his hire." If the British public only knew how the union doctor is paid for attending the poor, what he has to do, what he has to find for his niggardly salary, and the risk he runs of offending the officials of Bumbledom when he stands by the sick pauper and insists upon him having the necessaries and comforts that he would see his private patient had, surely they would, with national voice, one and all, condemn the machinery of the Poor-law Board as useless, totally inefficient to provide for the wants of the sick poor, and say it is nothing better than a piece of humbug from beginning to end. I am personally acquainted with one of the medical inspectors alluded to by you, and if, in one's indignation at their conduct, one should apply to them the epithet, "Toady advisers," instead of medical advisers to the Poor-law Board, I hope such strong language might be over-looked. You may depend upon it, Mr. Editor, the first time I have again the honour to be in company with my learned friend I shall point out to him the very great and heartless injury he is inflicting upon union medical men by such a line of conduct, which must sooner or later rebound on his own head. As surely as the trodden underfoot and over-worked slave turns in time against his oppressor, so will the poor-law medical men of the united kingdom in their turn rise *en masse* and assert their rights to fair and just payments for their labour in the same proportion as Government remunerates its other various officers of all classes. If all medical men felt as much love and respect for the honour of their profession as a few do, or did they possess as much independence as the collier, cab-driver, &c., how many would be holding union appointments now at the present salary? That is a question for the profession to turn over in their minds and digest most thoughtfully. A labourer says, I am worth so much, and so much I will have for my day's work, a mechanic does the same. Why cannot a medical man enjoy the same privilege? Why? for this reason, for want of unity of action and of friendly feeling, and of working together, the great with the small, for the mutual benefit of each other. Or it may be, that the consulting medical man does not really know what his humbler brother stands most in need of. I beg to thank you, as the Editor of THE MEDICAL PRESS AND CIRCULAR, for the generous and independent manner with which you always advocate the honour, and uphold the interest of the medical profession in every department, whether military, naval, or civil.—I am, sir, yours faithfully and obediently, HENRY W. WILLIAMS, M.D.

168, Fulham-road, London, S.W.,
April 16, 1868.

A FELLOWS' ASSOCIATION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I accept your challenge in the spirit in which it is made; I acknowledge your right to inquire—What are my views with regard to a Fellow's Association! and I will do my best to reply.

The charter of the College of Surgeons of England creates an elective body; but it is clear, that a large number of individuals, amounting to upwards of a thousand, would be unable to act as a body, unless they have the opportunity of meeting together and communicating their sentiments to each other. It would not be difficult to show that the electors of the College of Surgeons have never, latterly, acted as a body, but on every occasion as mere partizans; and in so acting, they have done injustice to their undoubted prerogative.

My proposition is, that the Fellows of the College should obtain permission of the Council to meet within the College, once or oftener in the year, to discuss questions affecting the general interest.

The first advantage which would result from these meetings would be the very important one of promoting an *union* between men who, under present circumstances, can never have the opportunity of meeting together; and, this union would be, as I hope, not one of person only, but also of heart and of mind.

As we stand at present, the Fellows are divided into sects, each sect centring around the temple of some Catholic saint, such as St. George, St. Bartholomew, St. Thomas, St. Mary, and so forth; and the tendency of this sectional division of our body is antagonistic to university union. The College of Surgeons is our University, the saints represent the schools, but the schools are members without Catholic essence unless they have the power of meeting together, and communicating their views at a common general meeting, such as that I now propose.

It may be unnecessary to appeal to the illustration of the "bundle of sticks;" but the fagot would have more weight and more power than the individual sticks, and the bundle might prove successful in the representation and redress of supposed injuries when the separate sticks would wholly fail. But to abandon metaphor, there cannot be a doubt that a representation coming from the whole body of associated Fellows would both be accepted and treated with respect by the heads of the College to whom it was addressed. It would have received the consideration of the many instead of the few; it

would be chastened by the unimpassioned thought of a large and interested body, and it would be treated with careful judgment by those for whom it was intended.

The opinions of a Fellow's Association would, in my mind, be the "vox populi" of the Profession; it would consider, it would reflect, it would suggest, and all the more temperately in proportion to its recognised status. Such an association, moreover, would be the best qualified to determine the priority and eligibility of candidates for election to the council; and it might be fairly expected that candidates who had received the *probatum* of a Fellows' meeting, would be generally supported by the Fellows at large. Indeed, it is hardly to be conceived that a candidate, impressed with the knowledge of the majority of Fellows being opposed to his claims, would still have the hardihood to tempt the chances of an election.

It would be difficult to anticipate what other questions might come before the Fellows for consideration; but, whatever they might be, an intelligent body, such as I am now contemplating, would have no difficulty in dealing with them.—I am, sir, your obedient servant, ERASMUS WILSON.

Henrietta-street, Cavendish-square,
April 16, 1868.

THE MEATH HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A notice having appeared in your journal of the 15th inst., to the effect that I had submitted my name to the Board of the Meath Hospital, as a candidate for the office of Surgeon to that Institution, will you oblige me by stating that such was not the case.—I am, sir, your obedient servant,

JOLLIFFE TUFNELL,
Surgeon to the City of Dublin Hospital.

[WE stated that Mr. Tufnell's name "had been mentioned amongst the actual or probable candidates." The statement was perfectly accurate, inasmuch as Mr. Tufnell's claims were not only freely canvassed in professional circles, but he was at one time spoken of as the most probable successor to Mr. Stokes.—ED. M. P. & C.]

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following account of the anatomical schools is from Professor Humphry's report to the Syndicate. These have answered well to the requirements of an increasing class of students of human anatomy during the past year. The dissecting room is well ventilated, well lighted, and commodious; and it has been fairly supplied. The superintendence of the students by Mr. Carver has been diligent and efficient. Lectures or demonstrations on practical anatomy have been given regularly in the lecture room by Mr. Carver and myself. A demonstration of minute anatomy has been given weekly by Mr. Gedge of Caius College, whose superior knowledge of that branch of anatomy I have been glad to render thus advantageous to the students. There is, besides, the more general course of lectures on anatomy and physiology, delivered by himself in the new museums, which are intended for students of natural science and students preparing for the special examination for B.A., as well as for medical students; and the opportunities thus altogether afforded for the study of human anatomy and physiology are very good. The arrangements in the museum for microscopical demonstrations have succeeded thoroughly; and, with the efficient aid of Mr. Gedge, and by the kindness of members of the University in lending microscopes, I have been enabled, on alternate Mondays, to give demonstrations of minute structure to classes of thirty or more at a time, and, so I hope, inspire an interest in this important branch of science. The current anatomical and medical periodicals, or many of them, are placed upon a table, and are accessible to the students and others who have the privilege of visiting the museum. The University Medical Society, numbering forty-five students besides the professors and teachers of the medical and natural sciences, holds its meetings in the museum weekly; and we hope that these incentives to visit the museum may operate as an inducement to more study of the preparations.

A very important acquisition has been the valuable collection of urinary calculi, presented by the Governors of Addenbrooke's Hospital. It numbers above 200 specimens removed by lithotomy or lithotrity in the hospital, and is accompanied by a catalogue giving a short history of each case with the result of the operation. To these are added the remarkable calculus of historic interest and of enormous size (weighing 33 oz.), long preserved in the library of Trinity College, and other specimens; making a collection of great practical and pathological, as well as scientific, interest. The work of arranging and displaying these properly in a suitable cabinet has occupied much of Mr. Carver's time during the summer, and is not yet finished.

The following specimens have, in addition, been added to the Museum:—

A series of eight fœtal skeletons; the skeleton of a young person, showing the epiphyses; a lower limb articulated to show dislocations; the upper and lower maxillæ at different periods of life; a head prepared to show the fifth pair of nerves; preparations of the ear; a cranium, with the bones artificially united; the skeleton of an aged rickety person; a wax model of the brain and spinal cord in situ; a skull, prepared to show the veins of the diploe. I must not omit to add that the handsome present of a valuable photographic apparatus with accessories, for taking representations of anatomical structure, has just been made by Dr. Ormerod of Brighton.

THE MUSEUM OF COMPARATIVE ANATOMY.

Many new specimens have been added to the Physiological and Osteological series in this Museum; and the foundation of a Zoological series, which was greatly needed, has been laid; many specimens have been remounted and several specimens better articulated so as to render them more serviceable for the purposes of study and demonstration. For particulars I may refer to the report of Mr. Clark, and will only add that much care has been taken in the selection of specimens, regard being had less to number than to excellence and suitableness for illustration of lectures or assistance in study. It is becoming a thoroughly good working museum; and I trust the students of Anatomy and Physiology will become more and more sensible of the facilities it affords for instruction, and of the advantages to be derived from resorting to so important a means of acquiring knowledge and stimulating thought.

HEALTH OF THE EX-EMPRESS OF MEXICO.—The *Nord* writes as follows:—"The health of the Empress Charlotte continues to improve in a manner that promises the best results for the future. But for certain fits of gloominess, which become less frequent from day to day, the princess no longer feels the cruel affection from which she has suffered. Sleep and appetite have returned, and with them the taste for study. The princess spends nearly the whole of the day in her room, and, except the royal family, receives no one."

SAD ACCIDENT.—A very painful case occurred last week, a poor woman of eighty-six years of age being admitted into Guy's Hospital for extensive burns over the surface of the body, from which she died in a few hours. The poor old woman's dress seems to have caught fire as she was seated opposite an open fire-place, and when no one else was present. She managed to run out into a yard, but there fell down in a state of exhaustion, and although the flames were soon extinguished, and she was carried to the hospital, she rapidly sunk, as might easily have been anticipated.

THE SENSORIUM COMMUNE.—In a review of Dr. Maudsley's work on the "Physiology and Pathology of Mind," which appeared in the *British Medical Journal*, the reviewer, while taking the author gently to task in regard to the sensorium commune, has complacently tumbled into a most strange blunder. So serenely unconscious, however, is he of his plight, that it would be a pity to take any notice of it, were it not that in doing so the opportunity offers itself of quoting some admirable words by Prochasha. They were published in 1784, and those who read them now will judge whether the eminent physiologist has received all the acknowledgment due to him from subsequent writers. The reviewer of Dr. Maudsley's book says:—"In the chapter on the sensory centres and sensation, the author should have been more explicit as to what he regards as the sensorium commune proper, or centre for the reception of the impressions made upon the nerves of common sensation. Though this is one of the disputed points of cerebral physiology at the present day, and one to which, by his plan, he was peculiarly bound, he evades the discussion of the question, and neither tells us whether he places it in the optic thalumus, or in the pons varolii." The

sensorium commune the centre for the nerves of sensation! This is more than strange in a critic, and might have entailed a whipping on a schoolboy. Surely a thought of the meaning of the Latin words might have warned him of his danger. The sensorium commune is the common centre of sensory impressions—the aggregate of the sensory ganglia—not the centre of common sensation. But the name has been so long used, and is so well understood by physiological writers, that the reviewer's blunder might pass comprehension, were it not evident that he learned it from Vulpian.—*Journal of Mental Science.*

PEPSINE.—Among the results of the application of science to the practice of medicine, none appear to promise more important benefits to those suffering from impaired natural functions than the introduction of Pepsine, the digestive principle of the gastric juice, which in a purified state, and mixed with some inert vegetable powder, or dissolved in wine, or made into a lozenge, forms a valuable and by no means a disagreeable medicine. It appears that the use of this important medicinal agent is greatly increasing as the knowledge of its effects becomes more fully established and widely diffused. There are few medicines that afford so ready a means as this does of testing its efficacy. A few grains of it put into a wine glass with some water forms at once an artificial stomach in which food may be digested, and in this way the relative values of different samples of pepsine may be determined. At a lecture that was delivered a short time ago at the Society of Arts, by Dr. Letheby, an experiment of this sort was made, in which large quantities of animal fibrine were digested in bottles during the lecture, with English (Morson's) and also with French Pepsine.—*Times.*

NOTICES TO CORRESPONDENTS.

DR. J. SMITH is referred to our issue for January 15.

CHLORODYNII.—You would do well to test the three articles mentioned, they may be equally good or *vice versa*. It is not our wish to advertise any particular person or article, except in the columns set apart for that purpose. There may be, and we believe there is, more than one manufacturer of genuine chlorodyne, but chemists generally dispense that originally introduced by Dr. J. Collis Browne, unless some particular maker's is prescribed. We cannot enter into the other part of the question—as to one maker being likely to allow chemists a larger profit than another, as an inducement to *push the sale* of his production, to the exclusion of other and better articles. We presume no respectable house, wholesale or retail, would be guilty of such a breach of professional confidence.

H. W.—Severe cases require probing, and the administration of caustic remedies is very needful in the present instance. We will offer you, and those of our numerous subscribers who are interested in the subject, every facility.

CONSANGUINITY.—Dr. Bernies, of Kentucky, has published some interesting and important statistics upon the result of marriage between blood relations. He states that "he has found that 10 per cent. of the deaf and dumb, 5 per cent. of the blind, and 15 per cent. of the idiots, admitted into the various charitable institutions of the United States, are the issue of marriages of first cousins." Such marriages are now prohibited in Kentucky, and several of the States; and a bill is pending before the New York legislature, prohibiting them under a heavy penalty.

ERRATUM.

LITTLE ON CONVULSIONS.—In our last issue, under this head, after Case 1, the paragraph "Sympathetic Convulsions" was misplaced. It was intended for the heading of Case 5.

THERAPEUTICAL COMMITTEE OF THE HARVEIAN SOCIETY OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to intimate to the profession, through the medium of your valuable journal, that we shall be glad to communicate with any gentlemen who would be willing to undertake the duties of Local Honorary Secretaries to this Committee for the districts in which they reside. We have already received offers from Dublin, Leeds, Birmingham, and Torquay.—We are, yours, &c.,

J. B. CURGENVEN, 11, Craven-hill Gardens.
WILLIAM HICKMAN, M.B., 1, Dorset-square.
Honorary Secretaries of the Therapeutical Committee of the Harveian Society.

MARRIAGES.

BEAUMONT—MOORE.—On the 26th ult., at the Scotch Church, Alexandria, by the Rev. James Young, M.A., Thomas Beaumont, Esq., M.D., F.R.C.S.I., to Jane Elizabeth, daughter of James Moore, Esq., Newtownards, Ireland.

HAMERTON—PARKER.—In Dublin, on the 15th inst., at St. Anne's Church, by Rev. G. W. Torrance, A.M., Matthew Hamerton, Esq. of Orchardstown House, in the county of Tipperary, only surviving son of the late General John Millet Hamerton, C.B., Colonel of the 55th Regiment, and formerly Lieutenant-Colonel of the 44th East Essex, which regiment he gallantly commanded at Waterloo, after serving in Egypt—to Josephine Eliza, eldest daughter of Joseph Parker, Esq., M.D., and T. C. Limerick. Immediately after the ceremony the happy pair left for the continent.

THE CANTOR LECTURES AT THE SOCIETY OF ARTS.

Dr. LETHEBY'S THIRD LECTURE ON FOOD.

CONSTRUCTION OF DIETARIES: PREPARATION AND CULINARY TREATMENT OF FOODS.

(Continued from page 325).

In the treatment of animal food there are several points for consideration. In the first place it is always best to prepare the animal for the shambles by fasting it for a few hours before it is slaughtered, as partially digested food, and the food recently absorbed into the system quickly pass into a state of putrefactive decomposition and taint the whole carcass; besides which, a day's repose is often necessary, to quell the excitement occasioned by the journey or voyage which the animal may have made on its way to the place of slaughter. In the second place, it is proper to remove as much blood from the body as possible at the time of killing, as this also is apt to pass into a state of decay. The regulations of the Jews in this particular are most effectual, and are derived from very ancient statutes in Leviticus, which ordain that no manner of blood, whether it be of fowl or of beast, shall be eaten by man; and with the view of letting as much of it flow away as possible, the practice is to slaughter every animal by cutting its throat with a sharp knife. There are, indeed, the most precise rules for this purpose. In some countries, however, the blood is regarded as a very nutritious part of the animal, and great pains are taken to prevent its escape. Dr. Livingstone says, that many of the South African tribes kill the beast by thrusting a javelin into the heart, so as to prevent the loss of blood. But in these cases the meat is never kept, but is eaten directly after the animal is slaughtered. A proposition has also been made in this country for killing animals by letting air into the pleural cavities, whereby the lungs collapse, and so cause almost instant death by asphyxia without loss of blood; but the practice is objectionable, not merely because of the liability of such meat to quick putrefaction, but also because of the difficulty of discovering disease in it.

In the third place it is proper that the carcass of the animal should be allowed to cool and set thoroughly before it is packed for conveyance to the market. If this is not attended to it soon decays. It should also be packed loosely or even freely exposed to the air, as the colouring matter of the blood and muscles continue to absorb oxygen, and to breathe, as it were, for some time after death, and while this goes on decay is arrested.

Lastly, all meat should be kept a little short of decomposition before it is cooked, or even until decomposition has just commenced, as the tissue then becomes loose and tender, and very digestible.

In the culinary treatment of animal food, the objects are fourfold:—

1st. To coagulate the albumen and blood of the tissues, so as to render the meat agreeable to the sight.

2nd. To develop flavours, and to make the tissue crisp, as well as tender; and therefore more easy of mastication and digestion.

3rd. To secure a certain temperature, and thus to be a means of conveying warmth to the system.

4th. To kill parasites in the tissues of the meat.

Now, as the researches of Dr. Beaumont and others have demonstrated that meat is always rendered more and more indigestible in proportion to the prolonged action of heat, it is highly necessary that the temperature should not be continued beyond the point necessary to accomplish these objects. Liebig says, that a temperature of 133° Faht. will coagulate albumen, and that the red colouring matters of the blood and muscle are coagulated and destroyed at from 158° to 165° (say 170°). He therefore advises that all cooking operations, in respect of meat, should be limited to 170°. His directions are that, in *boiling* meat it should be introduced into the vessel when the water is in a state of brisk ebullition, and that the boiling should be kept up for a few minutes. The pot is then to be placed in a warm situation, so that the water is maintained at from 158° to 165°. The effect of this is that the boiling water coagulates the albumen and tissue upon the surface of the meat, and to a certain depth inwards, and thus forms a crust which does not permit the juice of the meat to flow out, nor the water to penetrate into the meat. The flesh, therefore, retains its savoury constituents, and is not too sodden; but if, on the other hand, the meat be set upon the fire with cold water, and then slowly heated to boiling, the flesh undergoes a loss of soluble and savoury matters, while the soup becomes richer in them. The albumen, in fact, is gradually dissolved from the surface to the centre; the fibre loses, more

or less, its quality of shortness or tenderness, and becomes hard and tough. The thinner the piece of flesh is, the greater is its loss of savoury constituents.

This explains the well-known observation, that that mode of boiling which yields the best soup, gives the driest, toughest, and most vapid meat; and that, in order to obtain well-flavoured and eatable meat, we must relinquish the idea of making good soup from it.

If finely chopped flesh be slowly heated to boiling with an equal weight of water, kept boiling for a few minutes, and then strained and pressed, we obtain the very strongest and best flavoured soup which can be made from flesh. When the boiling is longer continued, some little additional organic matter is dissolved, but the flavour and other properties of the soup are, thereby, in no degree increased or improved. By the action of the heat on the fibres of meat, a certain amount of water or juice is always expelled from them; whence it happens that the flesh loses weight by boiling, even when emersed in water (as much sometimes as 24 per cent. of the weight of the raw flesh). In larger masses this loss is not so great.

Even in *roasting* meat the heat must be strongest at first, and it may then be much reduced. The juice which, as in boiling, flows out, evaporates, in careful roasting, from the surface of the meat, and gives to it the dark brown colour, the lustre, and the strong aromatic taste of roast meat. It is doubtful, however, whether the heat of 170° is sufficiently high to insure the destruction of the parasites of meat, and therefore, I would advise that the temperature should be as nearly as possible to that of boiling water (212°).

Of the four methods of cooking which are commonly practised in this country—namely, *boiling*, *baking*, *roasting*, and *frying*, the former is undoubtedly the most economical, and produces the most digestible food, but the flavour of the meat is not well-developed, and it is quite unsuited for many descriptions of meat: the flesh of young animals, for example, consisting of an undue proportion of albumen and gelatine in the tissues, will boil away to a large extent, and so will loose fatty tissue, like that of American bacon; and, indeed, unless the process is well-managed, there will always be considerable loss, as I have just stated, from the escape of albumen, saline matter, and the alkaloids of the meat, into the water, amounting sometimes to from 16 to 24 per cent. of the weight of the joint; and that these are valuable constituents of flesh, is proved by the experiments of the French academecians, who found that when a dog was fed daily upon half a pound of boiled flesh, which had been previously soaked in water and pressed, it quickly lost weight, as much, indeed, as one-fourth of its entire weight in 43 days; and in 55 days the emaciation was extreme. Of course, these observations do not apply when the liquor in which the meat is boiled is eaten with it, as in the case of hashes, stews, &c.

Dr. Pereira states that at the Wapping Workhouse, where mutton (chiefly fore-quarters) and beef (consisting of the brisket, thick and thin flanks, leg of mutton pieces, and clods—all free from bone) were boiled, the average loss in weight was only about 17½ per cent.; but this is under the common proportion, and shows that the meat was from old and lean animals. The ordinary loss of weight in cooking is about as follows in every 100 parts:—

	Boiling.	Baking.	Roasting.
Beef generally ...	20	29	31
Mutton generally ...	20	31	35
Legs of Mutton ...	20	32	33
Shoulders of Mutton...	24	32	34
Loins of Mutton ...	30	33	36
Necks of do. ...	25	32	34
Average of all ...	23	31	34

But although the loss of weight in baking and roasting is greater than in boiling, yet it is chiefly from evaporation, and from the melting of the fat. Flavours also are developed which give a pleasant relish to the meat; but there are many disadvantages to these methods of cooking, as that the surface of the joint is often overdone, when the interior is almost raw; and that the action of the heat on the superficial fat frequently produces acrid compounds (consisting of *acrolein*, and *fatty acids*) which are very distressing to a sensitive stomach. This is always the case when meat is fried or grilled, and is thus subjected to a temperature of 600° or more; in fact, all baked and roasted fatty foods are apt, on this account, to disagree with delicate stomachs; and it is often remarked that, although bread and butter, boiled puddings, boiled fish, or boiled poultry can be eaten freely without discomfort, yet toast and butter, or meat pies and pastry, or fried fish, or roasted fowl will disagree with the stomach. The practice of covering poultry and game with lard, or oiled paper, or thin dough, or even with clay (feathers and all, as is the Indian custom), and then roasting, is no doubt advantageous, as it modifies the temperature and prevents the formation of acrid fatty compounds. It was by some such a device as this that Aristoxenes was able to serve up a pig apparently boiled on one side and roasted on the other—the savoury crackling being suited for stronger stomachs, while the more delicate side of it was best adapted to weaker digestions.

In deciding, however, on the proper method of cooking a joint, regard must always be had for the kind of flavour that is to be developed. Shoulders of mutton and fresh beef are rarely boiled, because of their insipidity. The same is the case with game and poultry, for the barn-door fowl and turkey are nearly the only examples of the latter which can be boiled, and there are no such examples among the former. What should we think of a boiled pheasant? A story is told by a writer in the Society's Journal, of a poacher who wished to seduce a bumpkin new poacher by a practical illustration of the fine flavour of game, and calling at his cottage one day, he left for him a hare warm from the chase, telling him to cook it, and to try if it warn't a nice dinner for nothing. A week after he called again, and asked him how he liked his dinner. "Didn't loike it at all," exclaimed the recipient. "Well, man," says the poacher, "how did e cook en?" "Why, biled en in tarmuts to be zure." Exit the poacher disgusted; and so with venison, although it may be boiled, especially when it is rather high, for about half the time necessary for cooking it, yet it must be roasted for the other half of the time in order to develop its flavour. Hunters in the wild prairies of America, are accustomed to cook the flesh of the deer by *brittling* it in the following manner:—They strip off the long muscles from each side of the spine, both above and below, and tie them up in a roll, after well smearing them with oil or fat; they then roast them, and baste them perseveringly with oil. If opportunity permits they sprinkle them with lemon juice before they are oiled and made up into a roll. The flavour of roasted meat, and its grateful effect on the sense of smell, must have been recognised in very early times, for burnt-offerings are frequently spoken of by Moses as "a sweet savour unto the Lord," and particular accounts are given of the manner in which these offerings of the lamb and the kid, &c., were to be made acceptable, not merely to the Lord, but also to Aaron and his sons who were to eat of them. How far back in history the flavour of roast-pig is eulogised I know not, but it is immortalized in the essay of Charles Lambe. As for the process of *baking* meat it is not nearly so refined as that of roasting, although it has one advantage in the circumstance, that the temperature can be more easily regulated than with roasting.

In making *soup* the object is to extract, as completely as possible, all the soluble constituents of the meat or bone, and when the latter is used it should be chopped or broken into small pieces, and boiled for a considerable time—not less than nine or ten hours. Shin-bones will then yield about 19 per cent. of their weight of fat and gelatine—the soup being, according to Dr. E. Smith, very nutritious, so that 6 lbs. of bones will produce a soup that contains the nutritive power of 2 lbs. of meat, as far as carbon is concerned, and of 1 lb. of meat in respect of nitrogen; but although this may be so as regards the actual quantities of carbanaceous and nitrogenous matters

present, yet it is very doubtful whether they are equally nutritious, for in the renowned experiments of the French gelatine commission, it was found that the soup or jelly from boiled bones would not support the life of dogs, although raw bones, in like proportion, would.

Ox-tail soup is much richer than that from bones alone, as it contains the saline and other constituents of flesh. It is now a favourite and rather expensive soup, although, at one time, it was the humble fare, and almost the only nitrogenous food of the poor Protestant French refugees of Clerkenwell. Prior to the year 1689, or thereabout, the butchers of London left the tails attached to the hides, which were sent to the tanners of Bermondsey, but the poor French refugees, in their extremity of want, bought the tails for a mere trifle, and converted them into soup, which was soon found to be of excellent quality.

Soup made from meat should be obtained in the way already described—that is, a given weight of meat, chopped fine, should be allowed to macerate in its own weight of cold water, and should then be gradually heated to the boiling point, after which it should be strained and pressed. In this way about 3 per cent. of the nutritious matter of the meat is dissolved, besides the saline constituents. If the soup be simmered with the meat for some hours, a larger porportion of organic matter, chiefly gelatine, will be dissolved; and a good soup thus made from shin of beef will contain about 600 grains of solid matter in a pint, and of this about 39 grains are saline.

Lean meat contains about 25 per cent. of solid matter, the rest being water, and of this from 7 to 10 parts are soluble in cold water; rather more than half of this is albumen and myochrome (colouring matter), which are coagulated by heat, and thus if the cold solution of flesh be boiled, it contains only from 3 to 4 per cent. of the meat; and when evaporated to dryness it constitutes the *extractum carnis* of Liebig. It can hardly be said, however, that the nutritive power of this extract is very great, for its chief constituents are *certain acids, lactic* and *inosic*, with *inosite, creatine, creatinine*, and an indefinite colloidal organic substance of a brown colour and syrupy consistence, besides which it contains the soluble saline matters of the meat, as phosphate and chloride of potassium, with a little chloride of sodium. Analyses of this extract, as found in commerce, have furnished from 41 to 60 per cent. of water, from 22 to 41 per cent. of organic matter, and from 8 to 16 per cent. of saline matter. The extract is always acid, from the presence of lactic and inosic acids; and it should be of a pale yellowish brown colour, with an agreeable meat-like odour and taste. It should also be perfectly soluble in cold water, and should not contain albumen, fat, or gelatine.

False views have been entertained of the nutritive power of this extract, for as one pound of it represents the soluble constituents of from 30 to 34 lbs. of lean meat, or from 45 to 48 lbs. of ordinary butcher's meat, it has been assumed that its nutritive power is in this proportion; but Liebig has taken care to correct this error, by showing that the extract, when properly prepared, merely represents the soup or beef-tea obtainable from that quantity of meat; and as it is deficient of albumen, it must be conjoined to substances which are rich in this material, as beans and peas. No doubt the physiological action of the extract is due to the alkaloids and acids which it contains; and as the former of these are somewhat like the alkaloids of tea and coffee (Theine or Caffeine) in their effects on the body, it must be concluded that extract of meat is more of a vital restorative than a nutritious food. It is from this point of view that Parmentier, Proust, and even Liebig himself are disposed to regard the physiological effects of the preparations. "In the supplies of a body of troops," says Parmentier, "extract of meat would offer to the severely-wounded soldier a means of invigoration which, with a little wine, would instantly restore his powers, exhausted by great loss of blood, and enable him to bear being transported to the nearest field hospital;" and in almost the same language Proust remarks that "we cannot imagine a more fortunate preparation under these circumstances; for what more invigorating remedy, what more powerfully-acting panacea than a portion of genuine extract of meat dissolved in a glass of noble wine?"

As in the case of soup and beef-tea, its nutritive power must be assisted by vegetables and other substances which are rich in nitrogenous matters. Conjoined, therefore, with wheaten flour, with peas or lentils, or even with the gluten obtained in the manufacture of starch by Durand's process, it may be made to have the nutritive power of meat. Already there is a preparation of it by Messrs. Peek, Frean, and Co., in which the extract is mixed with baked flour and pressed into small biscuits; indeed, as far back as the year 1851, Mr. Borden, jun., obtained a patent for combining extract of meat with flour, farina, or meal, and baking it in the form of biscuits. In this manner, by using the extract of 5 lbs. of meat with 1 lb. of flour, he produced biscuits which contained 32 per cent. of nitrogenous matter, and 1 oz. of the biscuit grated into a pint of water, then boiled and flavoured, made a good soup. In the case of Liebig's extract of meat, one pound of the preparation is sufficient, with the usual rations of potatoes and other vegetables, to make soup for 130 men; and a strong broth is made by dissolving a teaspoonful of it (about 150 grains) in half a pint of boiling water, and flavouring with salt and pepper.

A still more nutritious broth, containing the albumen of the meat, is obtained by infusing a third of a pound of minced meat in 14 ounces of cold soft water, to which a few drops (4 or 5) of muriatic acid, and a little salt (from 10 to 18 grains) have been added. After digesting for an hour or so, it should be strained through a sieve, and the residue washed with 5 ounces of water and pressed.

The mixed liquids thus obtained will furnish about a pint of *cold extract of meat*, containing the whole of the soluble constituents of the meat (albumen, creatine, creatinine, &c.), and it may be drank cold, or slightly warmed—the temperature not being raised above 100° Ft. for fear of coagulating the albumen.

There are many questions connected with the economy of cooking which I have not time to discuss, but I may state that this Society has done good service for the community in obtaining valuable information as to the simplest and cheapest apparatus for the purpose. Foremost among them is the cooking-pot of Captain Warren. It is a sort of double sauce-pan, and is easily made by fitting a small covered sauce-pan into a larger one. The inner vessel contains the joint or other thing to be cooked, and the outer one has a little water in it, so that the temperature in cooking can never exceed 212°. By this means the joint is cooked in its own vapour without coming into contact with water or steam, and thus it cannot lose its soluble constituents; and if it be desired to improve the flavour of the joint thus cooked, it may be afterwards roasted for a short time before the fire. The loss in weight under these circumstances is not nearly so great as in the common way of cooking, and the flavour and tenderness of the meat are considerably increased; besides which, there is the certainty of cooking the joint equally throughout, and not over-dressing it. Moreover, by the adaptation of a steamer to the outer vessel, vegetables may be also cooked at the same time. When the meat is boiled by this process there is little or no loss of weight, and even when it is afterwards roasted, for the purpose of improving its flavour, the loss is not nearly so great as when a joint is roasted in the ordinary way. In one experiment it was found that 15 lbs. of meat roasted in the usual manner in the kitchen of the Cambridge Barracks, lost 4 lbs. 4 oz. in weight, whereas the meat cooked in Captain Warren's pot, and then roasted, lost only 2 lbs. 15 oz., so that there was a gain of 1 lb. 5 oz.

Another apparatus of very great ingenuity is a cooking-pot from Switzerland, where the saucepan containing the joint and a little water is, after boiling for a short time, placed in a box lined with felt, and thus left for an hour or two to cook, the conducting power of the felt being so bad that the heat is retained in the most perfect manner. The appa-

ratus is not only economical, but it is also excellently well suited for picnic parties, or for soldiers on the march, who may thus secure a hot dinner cooked while on the journey.

The cooking appliances of the poor are very imperfect, and hence they resort to the cook-shops of their neighbourhood; but even then their meals are scanty and wretchedly cooked. In the poor districts of London three halfpence is the usual expenditure for a dinner by children—a penny going in pudding, and the halfpenny in potatoes. If they pay twopence they are allowed to sit down, and have a little gravy with it. Everybody has heard how the poor of Paris dine *à la squirt*, where the tin soup basins are nailed to the table, and where the attendant Leonoras draw up the seething soup from an hidden cauldron by means of a huge syringe, from which it is driven out into the customer's basin. The price of the meal (4 sous) must be instantly paid down, or the callous handmaid sucks up the soup again into the monster squirt. Scenes like this, and even worse than this, in the abodes of the poor, have urged philanthropists to seek a better means of supplying their wants, without trespassing upon the dangerous ground of charity. In Paris an enterprising widow (Madame Robert) conceived the idea of giving the poor man a good dinner for twopence. Her daily bill of fare was cabbage-soup, a slice of bouilli (beef), a piece of bread, and a glass of wine; and thus, in the neighbourhood of the Marché des Innocents, did she daily provide for some six thousand workmen, who took their dinners in the open air, but sheltered from the weather; and she gained a farthing by each guest. In this country, a like benevolence has set on foot, with more or less success, in different places, restaurants for the poor. In Glasgow, for example, the working-class dining-rooms, which are far above the rude accommodation of Madame Robert, are established to provide a substantial dinner for 4d. or 5d. Long ago, the special correspondent of the *Daily Telegraph*, in writing about them, said that he obtained a capital dinner of good pea-soup, boiled beef, ten ounces of potatoes, and pudding—more than he could eat—for the sum of 5½d.; and a writer in the *Times* also stated that for 4½d. he had a pint basin of pea-soup, a plate of hot minced collops, a plate of potatoes, and eight ounces of bread; while his companion had for the same sum a pint basin of broth, a plate of cold beef, a plate of potatoes, and a slice of plum-pudding, all excellent in their quality, and well cooked. The practice in these places is to provide daily a variety of hot foods, as soup, broth, potatoes, rice, cabbage, pudding, tea and coffee, besides bread and butter, cold pressed beef and ham; and every ration, except meat, is so apportioned as to be sold at the uniform price of a penny. The meat costs three halfpence; and, with the view of clearing off the remainder of the soup after the proper dinner hour, so that a fresh quantity may be made every day, it is the practice to sell the soup and broth, at half-price, from six o'clock to eight o'clock in the evening, and then to give the remainder away. All the articles are of the best quality, and are well cooked. They are bought by contract at wholesale prices; and, although they are sold so cheaply, yet they yield a small profit, and so give the system the stability of a commercial enterprise.

Very recently, too, Mr. Riddle has proposed, in a paper which was read before this society, that arrangements might be made for cooking dinners on a large scale, and sending them out to the houses of the poor. He proposes to prepare, daily, good rations of roasted, baked, and boiled meat with vegetables, and to send them out in 2lb., 4lb., or 6lb. tin canisters, all ready for immediate use, and kept warm in little compartments of a properly-constructed cart. There would be no difficulty about this, and the meat might be delivered in excellent condition, and with great punctuality. None but those who are acquainted with the utter helplessness of the poor in the matter of cooking food, or who know the difficulties of even better classes of persons in this matter, can form any notion of the value of such a proposition; and I should be glad to see it realized.

Original Communications.

SIMPLE DISPLACEMENT OF FOOT.

By BENJAMIN TRAVERS, F.R.C.S.

I HAVE recently seen two cases wherein I believe the injury to have been of a rare though recognised form, viz., a simple dislocation or displacement of the foot forwards and outwards. That part remaining stiff or immovable. The sole being turned upwards and inwards, and the upper articular surfaces of the astragulus being very distinctly observed in their new and purely subcutaneous position.

In the first example, the injury seems to have begun and ended in displacement alone, involving no doubt the occurrence of a laceration of the anterior capsular ligament.

In the second case, the remote effects of the accident leave us no room to doubt that a very oblique fracture of the tibia extending into the ankle-joint determined or facilitated the escape of the foot from its normal relations, to the upper and lateral boundaries of the articulation.

The first case of direct displacement of the foot forwards, and of which accident I conceive the signs to have been very manifest, was lately exhibited and described to me by my friend, Dr. Hensley, of Alfred-street, Bath. It occurred as follows:—In the autumn of 1867, Mr. K—, a tradesman of that city, was riding on the back seat of a double velocipede, which had acquired such great speed in descending a hill, that he became frightened and jumped off. He came into contact with a hard road with extreme violence, feet foremost, the lower limbs being perfectly straight, and the feet extended to their utmost limit at the moment. The subject of this accident is a robust man between thirty and forty years old, having a singularly lean and projecting ankle.

It appears that the first local effect or result of the injury was considerable tumefaction, the superior articular face of the astragulus lying bare and prominent under the skin, which was tightly stretched over the bone, but in no degree torn or broken. The patient was of course unable to rise or stand; the further relation of this accident I will give in Dr. Hensley's own words: "The accident occurred at some distance from home, and I did not see the case until about two hours afterwards. The patient being muscular, and there being no efficient aid on the spot, I did not persevere in my first attempt at reduction, seeing that although I got the foot straighter, I could not restore it to its proper place. Having fastened the limb in a pillow, I brought the gentleman home in my carriage. On our arrival, he was immediately placed well under the influence of chloroform, and the reduction was at length effected with a good deal of force, the foot returning to its place with an audible snap. A mill-board splint was now applied, and the swelling gradually subsided."

Dr. H. goes on to say that several weeks elapsed before Mr. K. was put upon crutches, or allowed to attempt to walk. Though now convalescent, the gentleman appears to have recovered very slowly, and still complains of pain and weakness in the part on descending a hill. At this time (March, 1868) the ankle differs but little from its opposite in appearance, but the malleoli are not quite so prominent, owing to a thickening which remains just behind them and around the tendo-Achillis. In conclusion, Dr. Hensley affirms "that there has been a good and satisfactory recovery from the effects of a rare and formidable injury," an opinion which I apprehend will be readily endorsed by every one who is conversant with the remote effects of dislocation in a part so complex and important as the ankle-joint.

Case 2.—On the 21st January, 1868, I was summoned to visit Master N., æt. 15, tall and slightly formed for his years, who in the course of the morning had been thrown in a riding-school. He fell on the off-side of his horse, which had swerved abruptly instead of rising to the leaping-bar. This young gentleman was unable to move, and the left leg was seen to be twisted behind its fellow, the

toes of the left foot projecting, and being, along with the sole, fixed and abruptly inverted. There was complete immobility and great pain. A bystander seized the foot, and after a coarse and prolonged effort, succeeded in restoring the part to its right bearing in relation to the bones of the leg. Still, the patient could not stand; and after his removal to his own home I discovered a great sub-fascial effusion of blood along the lower third of the limb, and which for some hours appeared to be progressive. Presently Master N. was attacked with a violent subsultus tendinum, and he passed a very restless night. A free mercurial purge removed this disorder of the system, and it did not recur. I assumed for some days that there must be a fracture of the tibia at least, if not of both bones, in the immediate vicinity of the joint; but the swelling of the lower third of the leg was so excessive as to preclude the possibility of my ascertaining that fact by manipulation in the first instance.

I presently applied laterally two strong gutta-percha splints throughout the extent of the injured leg and ankle-joint, the foot being first firmly secured by plaster, and the entire limb being finally enveloped as high as the knee-joint by a six yard length of Churton's stocking bandage; the injured part was further secured by being tied into a large pillow, and by being allowed to rest on the heel in a semiflexed posture. At the end of one month I removed the splints, and now a cloth roller was applied, plentifully smeared with thick starch, and after wearing this "appareil" constantly for another five weeks, I substituted stripes of soap cerate spread upon cloth, also the stocking roller instead of the starched bandage. At the expiration of ten weeks exactly from the date of the accident, my patient for the first time sought to be allowed to stand and move about with the aid of a stout stick.

In this case the fact of the tibia having been broken obliquely into the joint became patent after the removal of the starched bandage, by which time all swelling had subsided. The line or track of new matter (callus), and a somewhat altered relation of the fissured extremity of the tibia (involving, of course, the internal malleolar process), whether to the knee above or the ankle-joint below, are now obvious. The part looks gibbous, and the foot has a decided twist, so that in walking the outer margin of the sole comes first to the ground, but there is no variation in the length of the two limbs, and progression is at this time effected with ease, with or without the aid of a cane.

Remarks.—Dupuytren in the "Lecons Orales," Article 10, vol. 1, also Hamilton, of Buffalo, in the United States, who has written a treatise which was published in Philadelphia in 1860, both speak of this form of displacement; but no where do I find any mention of fracture such as occurred in the case under my own observation.

M. Malgaigne affirms that of four or five examples which he had seen of this accident only one was unaccompanied by a wound, "Sans rupture des tegumens." It will be observed that at present I am not speaking of "Mr. Pott's fracture," so-called, but rather, if the expression might be permitted, its opposite. That is to say, that whereas in the case where the sole of the foot is turned outwards, the fibula is broken across at an uncertain distance above the ankle-joint, so where the pedal aspect is the converse of the above—that is to say, facing directly inwards, it will occasionally be afterwards found out that the tibia has been broken, although excessive effusion renders it impossible always to establish the fact with certainty, at the same time as that of the more apparent injury—viz., the dislocation of the foot.

I cannot conclude without observing, that on these occasions a surgeon is reminded of the very rare opportunities afforded to him for establishing beyond the reach of cavil all the local causes and consequences of a dislocation by a dissection of the recently injured parts.

Such records as we now possess in the works of Cooper, Dupuytren; Smith, of Dublin, and some others, are invaluable. All the true ginglymöid articulations are especially sources of doubt, when recent examination has not enabled us to verify apparent consequences; and further, it should always be borne in mind that the sudden accession of a great and progressive tumefaction will often baffle, and, for a time, arrest the exploratory powers of the most experienced surgeon.

CASE OF TETANUS FOLLOWING AN ATTACK OF CHOLERA.

By G. STEVENSON SMITH, L.R.C.S.E.,

LATE MEDICAL SUPERINTENDENT EDINBURGH CHOLERA HOSPITAL, 1866.

THE perusal of Dr. Walter G. Smith's interesting paper on paralysis subsequent to cholera, which appeared in THE MEDICAL PRESS AND CIRCULAR of February 26th, has induced me to lay the particulars of the following case before the profession. That cholera belongs to the great class of nervous diseases, is an opinion which is now held by many of the most distinguished physicians of the day, and the experience of that mysterious malady derived from a careful study of the cases which came under my care during the last epidemic, in the wards of the Edinburgh Cholera Hospital, leads me to believe in the correctness of this view. The disturbance of the nervous centres was especially well marked in the fatal cases occurring amongst children, in almost every one of which convulsions preceded death; while in the case of nearly all the adults who recovered, distressing and persistent hiccup harassed the patient, sometimes for days. In none of my patients was the choleraic attack succeeded by paralysis, but in the case about to be narrated the most violent tetanic spasms came on suddenly and unexpectedly during convalescence, and were clearly the result, I think, of the action of the cholera poison upon the ganglionic system of nerves.

C. A., a nurse in the Cholera Hospital, was seized with choleraic symptoms on the 13th October, 1866, which continued with severity for about three days. On the 16th she was feeble, but considered to be convalescent; and on the day following secondary fever set in; the tongue was parched and brown; the pulse full and bounding; there was great thirst, violent headache, &c. This attack continued till the 21st; and by the 24th she was so far recovered as to be able to go about the ward, apparently quite well. She continued to improve till the morning of the 31st, when she was suddenly seized with violent tetanic spasms of the hands and forearms. The lower jaw was likewise fixed. The fingers were firmly flexed on the palms, and the hands were forcibly bent to a right angle with the forearms. Attempts at extension were attended with much pain. She was in great agony; the face was flushed and the eyes anxious. At the same time she complained of prinkling in the feet and ankles.

The hands and arms were bathed with mustard and water, turpentine stupes were applied to the spine, and chloroform was administered. Large doses of the bromide of potassium were then given, with the object of relieving the spasms, but as this was productive of no good result, the patient was put upon the tincture of cannabis indica, thirty drops being given every three hours.

This treatment was commenced about 8 P.M. on the 31st, and towards morning the physiological effects of the remedy made their appearance. She talked and chatted continuously, and conducted herself like an insane person. About 4 A.M. the spasms of the left hand were overcome, so that she could partially open her fingers, but the right hand remained firmly clenched. No more of the cannabis was given during the 1st of November, but in the course of the day the spasms of the jaw and of the right hand gave way, and although the power of comprehension was very much enfeebled for some days, all tendency to spasm had passed away. She left the hospital in perfect health on November 6th.

THE RATIONAL TREATMENT OF CONSUMPTION.

By JOHN MULVANY, M.D., L.R.C.S.Ed., &c.,
ASSISTANT-SURGEON, R.N.

A CAREFUL perusal of the various methods of treatment advised for consumption will, I think, satisfy anyone that whatever claims each or any of them may have to the consideration of the faculty on the score of efficacy, few are advanced on that of rationality. Those most in vogue at the present time, on the continents of Europe and America, seem to have been suggested by observing the immunity from pulmonary tuberculosis which certain classes of animals and men enjoy—viz., the carnivora, the drunkards, and the obese, and since the cuisine is as completely dispensed with by the first, as the attractions of teetotalism or the allurements of the banting system are ignored by the others, raw meat, brandy, and saccharine materials have been looked upon as possessed of prophylactic properties; to endow them with curative virtues required but an inappreciably greater stretch of the imagination. Raw meat and brandy have, accordingly, been lauded as perfect cures in France, whilst the eulogiums bestowed on whiskey in America for its efficacy in most pulmonary affections, have elevated the imbibition of cocktails from mere dram-drinking into a necessary sanitary precaution. A similar logic causes the phthisical patient to be stuffed with grapes *ad eructationem* in some of the Rhenish provinces. Those methods would certainly be more rational which, based on the supposition that the disease is the result of a deficiency of certain elements in the blood, would seek to rectify the evil by ingestion of these elements, were such a deficiency established, and the *rôle* which it plays other than conjectural; or, again, that which, presuming that the suppression or vitiation of the healthy secretion of a particular gland is the point *de depart* of the malady, would endeavour to obviate injurious consequences by administering a preparation calculated to act as a substitute for said glandular secretion. But this theory, resting on the functions assigned the gland in question by C. Bernard, is open to the very serious objection that Bernard's views have been controverted by Frerichs and Lenz. However unsound this theory may be from the shaky foundation on which it rests, it is well deserving of attention, not alone for its ingenuity, but for its deducing the treatment from the supposed origo mali, a practice, unfortunately, but little observed in regard to phthisis; the treatment of which, if not empirical or special, is seldom rational, frequently routine, and too often confined to the symptoms. To pounce upon a single symptom, such as cough, or a train of symptoms—indigestion, debility, night-sweats, &c., and to seek to cure the diseaes by their removal, would be as logical as to attempt the eradication of the Fenian conspiracy by hanging Paddy O'Carroll in the wilds of Connemara; similarly irrational would be an attempt to extinguish the morbid cell-action in the lung by injections or inhalations, were means not taken to remove the pathological causes whereby the elaboration of fresh tubercle continues to be effected. But whilst the secondary effects of tubercle should not be neglected, our efforts should tend to the removal of its primary cause; to effect this a thorough appreciation of its pathogenesis will be our best guide, and whilst considering it absolutely essential that our knowledge of the morbid actions which lead to its production be complete, I by no means consider it important, as far as treatment is concerned, whether we adopt the views of Virchow, Rokitansky, Bennett, Dawson, &c., in regard to its actual formation, provided we recognise the element itself as the abortive offspring of unhealthy cell-action, a fact which alone stands saliently forth from the great diversity of views entertained on the subject.

The idea seems to be pretty generally entertained, that phthisis is a disease in which excessive oxidation is rampant, kindling a conflagration which rapidly consumes the hydro-carbons, disposing of fats with an avidity surpassing that of a Russian sailor for tallow, elevating the natural heat of the body several degrees, and requiring a *bonne bouche* of cod liver oil, alcohol, fat, or sugar to draw off its attack from the tissues. I shall endeavour to show that cod liver oil and alcohol play a different *rôle*, and that the debility, emaciation, and high temperature of phthisis have a different import to that usually assigned to them, and are attributable not to excessive but to deficient oxidation. Selecting cases for observation in which the phthisical patient is free from hereditary taint and devoid of the peculiar conformation of body supposed to predispose to it, we will find that the agencies whereby it was brought about were those by which the blood was insufficiently arterialised. The oxygen inspired was insufficient to effect the perfect transformation of the tissues, or the carbonaceous elements, which should have been eliminated *per cutem*, accumulate from the impediment offered to their excretion by a systematic disregard of personal cleanliness; the effects of the former *pur et simple* may be witnessed in the tubercle formed in the lungs of the Ethiopian inhabitants of the Antilles. These, remarkably cleanly in their persons, performing their ablutions with the frequency of the Mohammedan, and the efficiency of the South Sea Islanders, sleep as a rule, *ventre à terre*, on the crowded floors of their miserable shanties (beds being articles *de laxe*, only used in sickness or for a siesta), puffing the products of expiration into the nostrils of those of their relatives, who, stretched out in the same original manner, form a carpeting for the floor certainly unique, if not elegant. Thus in Nassau, the American Madeira, the climate of which is celebrated for its anti-consumptive qualities, the prevalence of the disease amongst the dusky children of Ham, forms a remarkable contrast to the immunity observed amongst the white settlers. On the other hand, amongst the blue-nosed inhabitants of the New Dominion, in whom a hydrophobic dread of water renders the condition of the cutaneous surface the antipodes of that observed amongst the West Indian negroes, and whose morning toilets are but a trifle more elaborate than those of the Osages, Indians, whose hands are never brought into contact with water, *en cado tierra su uso*, a sweet varnished cutaneous surface supplemented by the imperfect ventilation of their sleeping apartments, from which the cold wintry air is scrupulously excluded, brings about the same result. This is most conspicuous amongst the bateaumen, scowmen, and sailors. But in Cuba, the origin of tuberculosis may be studied on the grandest scale. In 1853, according to the tables of Don Ramon de Pina y Penuela medico mayor, &c., it appears that whilst one in 787 civilians suffered from consumption, the soldiers became phthisical in the proportion of 1 to 55. This marked preponderance of the disease amongst the military he attributes to overcrowding in small barracks, "*El hacinamiento de muchas personas in una misma habitacion.*" It may perhaps be imagined by those unacquainted with the Spanish soldier, that an irregular life had something to do with it; but, judging from my own experiences, I would say that the Spanish soldier is a model of sobriety. At the time of the allied expedition to Mexico in 1861, it was no unusual sight to see a French soldier or British marine describing Hogarth's line of beauty in his walk through the streets of Vera Cruz, but to see a Spanish soldier drunk was *nigroque similima signo*. I never saw one. Were the percentage of consumptive cases found amongst the crews of merchantmen or other small ships, where each man's berth contains but from four to twenty cubic feet of air, it would, I presume, equal that met with amongst the soldiers of the ever faithful Isle, a percentage so enormous as to strongly militate against the idea that a peculiar habit of body is necessary on which to engraft the disease. That a tuberculosis diathesis exists is unquestionable, but that persons having the peculiar build and all the insignia of predisposition often escape the disease is as obvious as is its production in those on whom no such significant traits denote its latency. I have lately had under my care a young man wholly beyond the suspicion of being

hereditarily predisposed, who became the subject of phthisis of such an acute character that in less than two months from its earliest symptoms a vomica had formed in his right lung, extending from the apex to the upper margin of the third rib, and measuring two and a-half inches in width, and in less than a month afterwards tubercle commenced to form in the apex of his left lung. The cause in this case was simply sleeping in a crowded apartment, where his twenty cubic feet of air was not perfectly renewed from without, whilst being vitiated by the air expired from the lungs of his comrades, who slept near him. The evil effects produced in this way were not in his case "owing to constitutional laziness, neutralized by active exercise in the open air during the day," as in the case of his messmates. What were the means whereby tubercle was engendered in this case? It could certainly not have been excessive oxidation, for physiologists tell us that the effects of respiration on the atmosphere are a diminution of its oxygen and an increase of its watery vapour and carbonic acid; and the experiments of Pettenkofer and Vogt show that more oxygen is absorbed during sleep than during the day. Thus, in this case there was a greater demand for oxygen when it was least attainable, and as a consequence defective æration of the blood necessarily ensued, from retained carbonic acid, &c., the effects of this retention being manifested with a rapidity inversely proportionate to the daily out-door exercise taken, and the cleanliness of the skin.

Under all similar circumstances, the accumulating carbonic acid, acting as a physiological stimulus to the heart, gives rise to one of the earliest symptoms of phthisis—viz., a quick, small pulse. Its acceleration at first is rarely permanent, because the accumulated stimulant is from time to time so reduced by open-air exercise, perspirations, &c., that the inhibitory influence of the pneumogastric being no longer overpowered, reduces the heart's action to its normal condition; the perspirations are therefore salutary, carrying off the superabundant carbonic acid, and thus assisting the lungs. The great amount of lung supplied to man, and the great capacity for the absorption of carbonic acid possessed by the tribasic phosphates, seem to evince that nature had foreseen and made provision to a certain extent against its undue accumulation. Her good intentions are, however, frequently frustrated; accumulation takes place: the blood insufficiently ærated is not adequate to the perfect nutrition of the nervous system, and various morbid sensations ensue—anomalous pains, lassitude, despondency, headache, and palpitation; the muscular system suffers *pari passu*, the imperfectly arterialised blood being unable to repair the waste of disintegration: debility and emaciation ensue, and instead of urea, carbonic acid, sulphuric acid, and water, resulting from the transformation of the used-up tissues into which they are converted during health, by a sufficiency of oxygen, various morbid products of sub-oxidation are formed, lactic acid instead of carbonic, oxalic and uric acids instead of urea, the amount of which in the urine becomes accordingly diminished; these thrown into the circulation cause from time to time a perturbation of system somewhat analogous to that produced by sudden suppression of the cutaneous secretions. Rigors result from irritation of the motor and sympathetic nerves, the latter by driving the blood from the skin by the extreme contraction of the small arteries produced, gives rise to the chills, which soon pass into flushes and perspirations, as the excitation of the sympathetic passes off, and is replaced by depression. During this state the tubular glands of the stomach are called into increased activity, on account of the increased flow of blood through the small arteries which supply them, and an effort is made to rid the system of the acids already referred to; in this way these organs become to a certain extent excretory as well as secretory. To the excess of acid thus thrown into the stomach the indigestion so frequently met with in the early days of phthisis, characterised by an enlarged and flabby tongue, usually of a reddish colour, less frequently, and in the more active cases, covered with a greyish yellow fur, deranged appetite, disinclination to fat, with acid eructations after its ingestion, may be attributed. "In diabetes," says Dr. Bence Jones, "cream, butter, fat, and oil, check the wasting of the body but in excess of acidity, these articles of food often give rise to great distress in the stomach." In this way the inability of some persons to take cod liver oil becomes intelligible. That this excessive acidity results from a deficiency of oxygen may be demonstrated by administering medicines, such as nitro-muriatic acid, chlorate or permanganate of potash, which, by yielding oxygen sufficiently abundant to effect the perfect transformation of the tissues, cuts off the source of its supply, and remove the dyspeptic symptoms, *sublata causa*, &c. The still further increase of carbonic acid in the blood, will gradually retard the circulation in the capillaries of the lungs, until finally, some of the apicial ones become blocked up by the clustering corpuscles, occasioning the dry, irritative cough of the early stages. Expectoration, at first frothy and scanty, afterwards more copious, and occasionally bloody, as the ore-distended capillaries exude serum or rupture, soon ensues. A greater activity of the respiratory and circulatory organs now comes on. The heart becomes permanently accelerated, and the blood therefore ejected with greater velocity, and in a smaller stream, from the right ventricle is propelled against the semistatic blood in the capillaries with such an impetus, that part of it is thrown back against the succeeding wave with such a rebound, that the arterial walls, narrowed by the elasticity of their coats to suit the diminished volume of the arterial stream, are so suddenly stretched, that a souffle is produced—a souffle which I am certain I have heard long before any formation of tubercle had taken place, and could not therefore be due to pressure; in this way the aneurismal dilatation observed by Lebert may also be accounted for. To a retardation in the capillaries succeeds a coagulation, a condition pretty generally conceded to be that which immediately antecedes the production of tubercle, and from which it is manufactured, possibly by the cellular, nucleur hypertrophic, or cytogenetic, &c., methods; or, possibly, some of the superabundant fibrine which results from imperfect secondary assimilation, or from insufficient oxygen to reduce it to products of lower composition, as Lehmann explains its increase in pneumonia and pleuritis, becomes deposited, as in other hyperinotic diseases, and by its presence or pressure may, acting as Dr. Lionel S. Beale shows a grain of sand on the conjunctiva to do, so alter the conditions under which cell-life was normally carried on in the cellular sheath of the blood-vessels, that a freer access of pabulum to the germinal matter takes place, increased multiplication of cells ensues. Proliferation thus stimulated by one inordinate supply of deteriorated material is carried on with an activity incompatible with the formation of an homologous product; tubercle results encroaches on the neighbouring structures, softens in the centre, breaks down, is expelled by expectoration, and leaves a vomica.

A vomica appears to me to be a species of propaganda for the conversion of healthy lung into fresh tubercle; issuing as emissaries, the morbid impressions it produces on the nerve filaments in its propinguity to the circulatory and respiratory organs, it sets *en train* a cycle of actions, which eventuate in its own aggrandisement, or in the formation of a new vomica, furnishing thus, in the periodical formation of fresh tubercle, the most obstinate impediment to a successful treatment. What breathing a vitiated atmosphere is to the production of the primary heterologous formation, that is a vomica to its subsequent development. The patient may have been removed to a healthy atmosphere, may have a first-rate appetite, a capital digestion, may take open air exercise, be strictly observant of hygienic requirements, have but slight cough, little expectoration, and no night sweats, and be gaining in weight at the time that fresh tubercle is being formed. This gaining in weight, usually regarded as indicative of the favourable progress of the disease, though by no means incompatible with the formation of new tubercle, is a con-

summation most desirable to witness, inasmuch as it shows that the digestive functions, no longer embarrassed by excessive acidity, are being healthily performed, that healthy chyle is being poured into the blood, and that assimilation, primary and secondary, if not quite perfect, is not far from being so. Nevertheless, the respirations remain quickened, the pulse accelerated, and the temperature of the body high, evincing the vitality of the disease, and prognosticating an impending exacerbation from the tuberculous material which is even now being fabricated. The means whereby this is effected are, I am inclined to think, brought into operation by the vomica thus:—By the morbid action going on in its interior, the nerves which ramify on its walls are necessarily irritated, and these being furnished by the pulmonary plexuses anterior and posterior formed by branches of the pneumogastric and sympathetic, the irritation extends to the trunks of these nerves; by the vagi 'tis transferred to the muscles, which co-operate in respiration, stimulating them to increased frequency of action, but as the bronchial muscles are nearest to the seat of irritation, and are, moreover, subject to the frequent contact of offensive sputa passing over them in expectoration, as well as to the influence of the carbonic acid, which severe coughing causes to accumulate, it is not unreasonable to suppose that they are thrown into a state of spasm just as are the urethral muscles by acrid matters contained in the urine, or the sphincter of the pupil by neuralgia of the supra or infraorbital nerves. By this spastic condition the expulsion of sputa from the vomica is rendered difficult, the impediment which it offers giving rise to a heart-rending, frame-shaking, often house-shaking cough, almost as unendurable to the listener as the subject of it, and which nature, more potent and not less pitying than man, relieves in her own way—transferring the irritation to the stomachic extremity of the pneumogastric, she relieves the spasm by the vomiting induced. The same condition of bronchi offers also an impediment to the free entrance of air, and thus the blood moving but slowly in the capillaries on the walls of the vomica, for reasons that will presently appear, tends to stagnate from the undue amount of carbonic acid with which it remains charged. The irritation propagated to the sympathetic through the pulmonary plexus, seems to be more widely diffused, extending to the heart and arterial system, but as in the case of the pneumogastric, we may suppose the irritation is most felt in contiguity to the seat of the irritant, and that those blood-vessels on the walls of the vomica are most influenced by it. The experiments of Dr. Loven on the dilatation of arteries from nerve irritation seem to warrant this conculsion, since a diminution in volume occurred in the vessels in proximity to the irritant quite as often as dilatation. The greater contraction of the coats of the small arteries on the walls of the vomica will accordingly render the transit of blood through them less facile than through those vessels less constricted, and the circulation in the capillaries to which they lead is consequently rendered slower, whilst the diminished vis a tergo not being able to propel the blood onwards through the pulmonary veins against the resistance offered by the prolonged expiratory efforts which take place in coughing, causes congestion to take place, which is further favoured by the impediment offered to the free interchange of gases by the spastic condition of the muscular fibres of those bronchi which lead into the vomica. Or the same result may be brought about in the manner witnessed by Dr. Norris—"When," he says, "the spastic contraction of the smaller arteries took place, there was a reverse current into the capillaries from the veins, which continued until the capillaries remained full. This fullness remained permanently, or until relaxation of the artery permitted arterial blood to be propelled into them; coagulation, irritation, changed condition of life in the cells of the connective sheath of the blood-vessels and tubercle, are the subsequent steps." But why have we not a souffle produced as in the first instance, by the diminished calibre of the small arteries, and the congestion or coagulation of the blood in the capillaries beyond them? Because the contracted condition in which these vessels are held by the irritated sympathetic prevents their sudden dilatation by the shock of the rebounding against the ongoing blood-wave, the greater contraction in which I conceive those small arteries to be held, which ramify on the walls of the vomica, does not extend to those more remote. The impediment, therefore, which they will offer to the circulation will, from their limited extent, be insignificant, and will not suffice to produce arterial tension during the systolic action of the heart, as the obstructed blood will readily pass on through the neighbouring channels.

(To be continued.)

OSSEOUS ANCHYLOSIS OF THE LEFT HIP-JOINT, WITH RECTANGULAR DISTORTION, CURED BY OPERATION.

By H. W. BEREND, M.D.,

DIRECTOR OF THE ORTHOPEDIC INSTITUTE OF BERLIN.

(Read before the Surgical Society of Berlin.)

Case 1.—M. H. Wilhelm Kruger, 27 years of age, of Klein Wischnewskow, near Zempelburg, was sent to my establishment by Dr. Vossius, residing at the latter place. The patient had formerly been in uniform good health, and dated the commencement of his disorder from Michaelmas, 1860, when he experienced attacks of cold and heat, with acute pains in the right arm and in the back. He was bled, which relieved the pain in the arm, but the attack of acute rheumatism was now directed with great violence to the left leg, and produced, after confining him twelve weeks to his bed, the uncommon and

Fig. 1.

serious deformity (See Fig. 1) which continued down to the time of his admission to my establishment on the 30th April.

Erect position.—If the patient wished to stand upon both feet, though unable to bring more than the anterior third of the left sole in contact with the ground, he was compelled to support himself with both hands on his knees. The upper part of the body was inclined at an obtuse angle forwards to the left. The whole left lower extremity was thrown obliquely outwards. The right side of the nates projected, the left being flattened. Both knees, but especially the left, were bent at obtuse angles. The spinal column formed, with the dorsal lumbar portion, a considerable curve to the left.

When the patient tried to stand free without placing his hands on his knees, he could only do so with the right limb, which then appeared perfectly straight; the knee, including the left pelvis being depressed about 2″, the left thigh being bent and thrown out at right angles. Seen from the back, the spinal column quite normal, the left side of the nates somewhat flattened; the fold, however, being perpendicular. The knee could be placed in any position at pleasure (see Fig. 2).

Fig. 2.

Horizontal position on the back. Small of the back in contact with the bed; right extremity normal, left pelvis 2″ lower, left thigh thrown out strongly at right angles, and anchylosed. On endeavouring to impart somewhat of a rotatory motion to the hip-joint of the diseased thigh, some apparent mobility was obtained, but this was evidently due to the synchondrosis sacro-iliaca alone (see Fig. 3).

Progression without stick or crutch feeble in the extreme, and is accompanied with depression of the left pelvis, the upper arm being supported on the knee, the left pelvis being moved simultaneously and the body powerfully inclined forwards and to the side.

The facts just detailed have been corroborated by presenting the patient to the Medical Society and to the Gesellschaft für Heilkunde in Berlin ("Medicinische Central Zeitung" for 1862, No. 47), and left no doubt as to the treatment in this extreme and rare case of deformity.

The decided osseous anchylosis by which the thigh had been thrown out at a right angle with the acetabulum and immovably fixed there, could neither be overcome by pure orthopedic-gymnastic treatment, nor by myotomy, as it is evident that these remedies could have no effect whatever in removing an osseous adhesion; and operations not involving loss of blood, such as forcible manipulations, were rejected on account of the peculiar nature of the deformity in question, as being of more than doubtful tendency. fractures of the pelvis itself probably attended with fatal effects being easily possible from the employment of such remedies. No alternative remained save either to consider the case as a noli me tangere, or, confiding in former experience, to attempt osteotomy, cutting out a wedge-shaped piece of bone; this proceeding affording, according to all experience, the greatest chances of success, compared with simple excision (*vide* "Heyfelder Statistik der Resectionen" 1861, p. 94).

I performed the operation on the 10th May, 1861, assisted by Drs. Schwartz, Barschall, Rauch, Rosenkranz, and others, in the following manner (see Fig. 3):—

Chloroform administered. The patient lying on the side turned somewhat to the right. First step—an incision of three inches into the skin, commencing somewhat above the trochanter on account of the abnormal position of the thigh, extending obliquely towards the outer side of the body, through skin and cellular tissue down to the bone. The bone, white and shiny, was visible at the bottom of the wound. The portion of bone to be cut out exposed. Excision with Charrière's saw, and finally with a small hand-saw which I preferred to the chain-saw, because the bone being deeply embedded, rendered the manipulation with the latter difficult in the extreme. The sawing through of the last piece of bone was connected with extraordinary difficulties. Immediately after it had been completely severed, the normal position could have been thoroughly restored to the deformed leg, but at the same time, I was convinced that the two ends of bone cut through would be so closely pressed together as to render the failure of the desired *Pseudarthrosis* highly probable. I therefore preferred—

2. Removal of as wedge-shaped a portion as possible of the femur. This process was likewise attended with excessive difficulties, and notwithstanding that the portion of bone to be removed was partially visible and accessible from the incision, it required troublesome labour with chain and hand-saw before a piece of bone about three-quarters of an inch at the base, and tapering to somewhat of a wedge-like form, could be removed. The excision of an accurately wedge-shaped piece was, under the circumstances, impossible.

The whole operation lasted about an hour and a quarter. The hæmorrhage was, under the circumstances, not extreme. No vessels were taken up. My hooks were of great use, as well for affording a better view into the interior of the wound as in retarding hæmorrhage.

The wound was united partly by silk, partly by silver sutures. A compressive dressing of lint, plaster bandages, &c., was employed to stop the effusion of blood. The whole limb was enveloped in wadding, and the patient placed in one of Bonnet's cradles. On account of a former rheumatic disposition, I refrained from local cold applications, but otherwise ordered a strictly cooling regimen.

In the evening the pulse above 90. Patient restless, not complaining of pain however. The lower parts of the dressing red-coloured, but not to such an extent as to cause any alarm as to too great a loss of blood. I therefore considered these secretions as curative. Notwithstanding the administration of ¼ gr. of morphium the night was restless. Towards morning vomiting occurred twice.

On the 11th May, at half-past seven A.M., pulse 100 and full. Appearance satisfactory, tongue furred (white); no pain; somewhat less restlessness; moderate quantity of blood oozed away. Patient drank a cup of milk, and slept for several hours.

Evening.—Pulse 120, no pain; a bloody serous secretion oozing through the dressing, rendering frequent change necessary. Nothing else to complain of.

Night.—Five hours' sleep.

May 12. at 8 A.M.—Appearance good, no complaints; tongue furred (white); pulse 120; secretion from the wound less coloured, but still red.

At 11 A.M.—Pulse reduced to 100; all going on as well as possible.

Evening—The same condition.

Night—Gentle sleep.

May 13, 8 A.M.—No complaints, pulse reduced to 90. Secretion very copious, but not very offensive in smell. Tongue beginning to look cleaner.

May 14.—Removal of first dressing and bandages. Wound half united; dry dressing.

General health in the evening excellent; pulse 90. Dr. von Zizurin, from St. Petersburg, who happened to be at Berlin, examined the patient with great interest.

On the 6th day, six sutures removed; on the 8th day the others. The particulars of the subsequent treatment and cure offer no special points of interest, save that of the periodical appearance of erysipelas, which, as it attacked sometimes the front part of the thigh, and sometimes the back and left side of the nates, could only be regarded as the reaction of the secretion of decomposing matter in the bottom of the wound, which took place in the first months. This decreased with each removal of the secretion, which was further promoted by poultices, and save an incision into the fore-part of the thigh, no artificial assistance was required. Care had to be taken, however, to avoid all irritation whatever, and on this account the proper orthopedic dressing with Bonnet's stocking had to be entirely laid aside in three weeks, as it prevented the degree of cleanliness so absolutely necessary for the cure; besides which the application of a simple sand-bag was sufficient to fix the limb and to prevent any new deformity in the hip. Under the favourable influence of good ventilation, and proper food, the patient was within four months so far recovered that the first trial was made in standing erect. The cure then proceeded gradually, warm baths being used daily, and the hip being carefully *rotated*, until in February, 1862, the first experiment in walking was made, the patient wearing a boot, the sole of which was raised 1½", and he was able to take proper gymnastic exercise without pain, small portions of necrosed bone had been removed before this date, from time to time, by artificial means, some coming away of themselves.

At the present time, the beginning of April, therefore ten and a-half months after the operation, the patient, now presented to the notice of the society, can accomplish considerable distances with the assistance of a small stick only (see Fig. 4). The pelvis is quite straight on both sides, and both sides of the nates as well as the trochanters lie in nearly a right line. The left trochanter projects a little in consequence of a slight exfoliation of bone. The actual shortening of the thigh by one and a-half inches, consequent upon the operation, was manifested above the knee, but is so completely compensated by the elevated sole of the boot as not to be in the least perceptible in walking. It is true that no new hip-joint, in the strict acceptation of the term has been formed, but in consequence of the Pseudarthrosis process which has taken place, none of the functions of the thigh are impeded, with the exception of flexion to a slight extent, all the other motions, forwards, backwards, and sideways (chiefly by means of the ilio-lumbar and sacral articulations), are so readily performed that the former cripple, who has been so fortunate as to recover command over his hitherto useless limb, is enabled to go through even difficult gymnastic exercises (such as swinging on a double rope, &c.) without extraordinary exertion. This result is the less remarkable, as the muscles of the limb operated upon do not differ in the slightest degree from those of the sound one. Finally, that the general condition of the patient is as good as could be hoped for is evident from his healthy appearance.

Case 2.—"PES EQUINUS ACQUISITUS" IN CONSEQUENCE OF A COMPOUND FRACTURE OF THE LOWER THIRD OF THE LEG WITH OUTWARD LUXATION OF THE FOOT—EXCISION OF A CUNEIFORM PORTION FROM THE TIBIA AND FIBULA—CURE WITH RESTORATION OF NORMAL MODE OF PROGRESSION ON THE NATURAL SOLE OF THE FOOT.

Friederich Peterson, 16 years of age, of Dornau, near Wittenberg, son of a landed proprietor, dated his sufferings from a fall from a tree, which occurred two years prior to his admission. The compound fracture which ensued at the time was followed by high fever and secretion of matter, which did not cease until some months later, when a considerable splinter of bone was thrown off. On the reception of the patient in my establishment (May 7, 1861) the following facts were observed:—

In an Erect Position.—He appeared standing on the extreme tips of the toes, the heel remaining four inches from the ground. The ankle, on which was a star-shaped scar, projected outwards, and the leg formed almost a straight line as far as the knee, the foot assuming an oblique direction inwards (see Fig. 5).

In Sitting.—The deformity of the foot just described remained unaltered, the ankle projected abruptly outwards, the tendo-Achillis in a state of extreme tension. The deformity remained unchanged after attempts at reduction. Temperature and colour of the foot normal. The muscular development of the calf differs in size from that of the uninjured leg by about an inch. The thigh was also affected by atrophy, so that it differed from its fellow by about an inch.

In walking, the patient trod with the toes only, the foot being somewhat bent outwards.

All the motions of the foot, flexion, extension, &c., had entirely ceased; those of the toes only, and that to a very slight degree, were present. In the tibio-tarsal-joint not a trace of movement. It is possible, however, that I may have been deceived in this point, but the unsuccessful section of the tendo-achillis, and the employment of the orthopedic method, with an entirely newly-constructed club-foot machine of great power, for a space of more than two months, without the least benefit, convinced me that, besides club-foot, osseous deformity in the tibio-tarsal joint had to be dealt with. Nothing remained, therefore, but osteotomy of the tibia and fibula. This operation I performed August 11, 1860, with the assistance of Drs. Schwartz Wolfert, Gœbel, Rosenkranz, and others, in the following manner:—

1.—*Osteotomy of the tibia.*

A two-inch long incision was made in the skin over the crista, from the commencement of the lower third of this bone, the periosteum laid bare, and a wedge-shaped piece of bone about an inch at the base sawn out by means of a chain-saw, and then a hand-saw. The piece was removed by the double-dissecting forceps.

2.—*Osteotomy of a portion of the fibula an inch in length, the skin having been cut through.*

No vessel was taken up. The parts of bone after the excision were brought together and fixed with plaster of Paris dressing, so that the sole of the foot was brought into a position at right angles with the lower leg. After the operation, the toes exhibited perfect power of motion. Ice-bladder applied. At night morphia and antiphlogistic treatment (see Fig. 6).

The dressing was obliged to be removed on the fifth day, and was replaced by simple splints. For months after this time the foot remained in a padded case, so that the dressing could easily be removed and changed, and the wound inspected. The reactionary fever, although at first severe, did not become excessive during the first few weeks. Save in the first stages of the treatment, no morphia was required. The patient slept regularly at night, and did not suffer serious loss of appetite. Both wounds caused by the operation exhibited from the very first excessively abundant granulators; indeed, in the first six weeks, of so loose a nature that they resembled fungus, and rendered astringent treatment, with quinine and tincture of myrrh, necessary. This was, however, nothing but the beneficial efforts of vis medicatrix naturæ. Hæmorrhage ensued several times, most copiously in September, from the wound in the fibula. It was stopped by compression.

In the beginning of the fifth month the bone had consolidated, and the normal sole restored (see Fig. 6). For the last three weeks the patient has been walking on the sole of the foot with the aid of a shoe raised an inch and a-half. Necrosed portions of bone have been thrown out from the wound, but to a very trifling extent. In the last fortnight some small splinters came away from a sore in the calf. The skin is still thin over the fore-part of the leg, and inclined to erosion. In other respects the condition of the patient is as favourable as could be hoped for. (See Fig. 4.)

FOUNDATION OF NEW PRIZES.—The Academie des Sciences has had added to its already rich list of prizes a bequest by M. Serres of 60,000 francs, for the purpose of instituting a triennial prize for embryology. Also Madame Poncelet, widow of General Poncelet, the great geometrician, has expressed her intention to honour her husband's memory by founding an annual prize of 2500 francs, which the Academy will adjudge to the author of the best work on pure or applied mathematics, whether published in France or abroad.

SMALLPOX and typhus are raging at Tripoli. Among the recent victims is the Arab chief Georgi, well-known for his munificent hospitality to European travellers.

REPORT OF AN OPERATION FOR HERNIA CEREBRI: WITH OBSERVATIONS.

BY DR. MED. H. HIRSCHSPRUNG.

Translated, with abridgment, from the *Ugeskrift for Læger*, Nos. 16-19, March and April, 1867.

By W. D. MOORE, M.D. Dub. et Cantab., L.K.Q.C.P.I., M.R.I.A.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 332.)

In now proceeding to speak of the second form of hernia cerebri, *encephalocele*, it will be seen that its genetic relations are highly uncertain. Spring entertains the peculiar opinion, that a meningocele always precedes it, and according to Houel, Malgaigne holds the same view. If the opening in the bone be large, there is disposition to hernia; but this will not be able to form until after birth, as it is not until after that period that the propulsive forces (forced respiratory movements, crying, sneezing, vomiting, coughing), which are necessary to protrude the brain, come into play. In the congenital encephalocele the serous fluid is gradually absorbed, and the swelling, which in its first period is transparent, subsequently becomes soft and pasty. The cases hitherto described have never shown themselves in the sutures or fontanelles. The occipital region is the most frequent seat, the rarest is the anterior part of the base of the skull. Houel, who denies the occurrence of meningocele can of course not assent to Spring's view, which is certainly highly problematical.

Houel seems not disinclined to see in encephalocele only a result of an hydrocephalus, which has existed in a very early stage, but has subsequently been arrested in its development, so that we need find only slight dilatation of the cerebral cavities. The earlier current view of the occurrence of the hernia as the result of defective ossification at one point or other, and consequent diminished power of resistance to the pressure of the brain, has of necessity been given up, as the hernia, as we have said, occurs at all events only exceptionally in the sutures and fontanelles, which nevertheless, if the former view were correct, would seem to present the necessary conditions.

It of course cannot be my intention, with the experience at my command, to attempt to judge between the contending parties. But as a result of the prevailing uncertainty I shall not omit to communicate a case I have had under observation, which appears to me to open a new point for consideration.

On November 22, 1866, I had an opportunity of examining a cerebral hernia in a female infant born six or eight weeks before its time, which was brought into the Lying-in Institution. It had not survived its birth. The head was very small, and the tumour hanging on the nape of the neck was of the same size. The bones of the head were well ossified, and lay close together with linear sutures and without fontanelles. The tumour had a raphe, dividing it into a larger right and a smaller left portion. The raphe had in one part a cicatricial appearance; the skin nowhere exhibited openings. The tumour was soft and elastic, evidently without any fluid contents. Its base was broad, and it protruded through a large opening in the occipital bone, one inch in diameter, which occupied almost the whole squama, so that only a bony angle, one-third of an inch in breadth, remained superiorly, while down towards the foramen magnum only a fibrous cord formed the boundary. When the arch of the skull was removed, only a third of the brain, which in size corresponded to the age of the fœtus, was seen situated in the cavity, while the remainder and the cerebellum lay out in the sac. The cavities of the brain had probably everywhere been a little distended; but this was true especially of the posterior horn, particularly of the right, which was considerably dilated, though without fluid. There was no rupture. The great cerebral ganglia, the tubercula quadrigemina, and the pons varolii lay in the hernia. From the right thalamus proceeded a small club-shaped, soft polypus, and a couple of similar ones from the left. The parts of the cerebral hemispheres lying in the hernia were about equally large for each side, so that the raphe did not correspond to the median line. The excessively strong ossification of the base of the skull, which was much shortened, was striking. The body was otherwise well formed.

This case is best described as a considerable, but simple cerebral hernia. There was no fluid in the hernial sac nor in the cavities of the brain; but the extensive dilatation of the latter in parts rendered it sufficiently evident, that at some time hydrocephalus had existed. Thus far the case would seem to favour Houel's theory above referred to. But there was at the same time a circumstance connected with the bones composing the base of the skull, to which I shall direct attention. No defect existed, but combined with a very small size of the cranium in proportion to the age of the fœtus, there were excessively advanced ossification of the several bones and union of different parts, which at so early a period would normally be separate, and some of which are usually not united until long after birth.

[Here follows a minute description of the parts so abnormally ossified and united.]

We might now consider this morbidly augmented ossification as a secondary phenomenon, produced after the formation of the hernia, and caused by a concentration of the ossific action within a smaller superficial space. But we may also in the strong ossification of the several bony parts, and in the premature union of sutures, which normally should be open, see the reason of the arrest of development of the cranium, and the consequent necessity for the brain, whose development progressed, and whose size constantly increased, bursting its limits and exceeding the space which would restrain its growth. This explanation appears to me to be perfectly physiological, when we are aware of the influence of the sutures upon the growth of the bones. What the result is when the brain remains in its bony capsule is satisfactorily shown, especially by Virchow's investigations respecting the heads of cretins and of idiots. It would lead us too far to enter upon these interesting researches; but I cannot avoid pointing out the remarkable analogy between the state of things at the base of the skull in cretins, as Virchow has described them in an article in his *Gesammelte Abhandlungen* (Zur Entwicklungsgeschichte des Cretinismus und der Schädeldifformitäten), and those found in the last described fœtus.

It will be remembered, that in the latter were found signs of a previously existing collection of fluid in the cavities of the brain, and it is not possible to form an opinion how far this has had any influence in the production of the prolapse of the brain; but a principal part it has scarcely played. I am thus led into the question of the *connection between hydrocephalus and the strong ossification of the bones of the skull*. In opposition to the general view of the necessary connection of hydrocephalus, and highly distended sutures and fontanelles with feeble development of the osseous substance, I shall adduce our experience that strong development of the bones of the cranium and hydrocephalus not unfrequently go together. In my essay on occlusion of the œsophagus I have brought forward two cases (11 and 14), and if we look to the hemiacephalæ which, according to the general opinion, are due to the concurrence of an hydrocephalic brain, and observe the partially strong development of the fundamental parts of the cranium, we obtain a further proof of the frequency of the coincidence. With Virchow we ought certainly to see in an inflammation the common cause of the morbid process in the two different places. The assumption appears to me to be obvious, that a disturbance of equilibrium between the two processes may be the condition of the development of both hernia cerebri and hemiacephalus. If the hydrocephalus acquires the preponderance, the brain perishes, the calvarium bursts and collapses: hemiacephalæ are formed; if the hydrocephalus be less considerable, while the ossification of the cranium is in a state of high development, the conditions for hernia cerebri, as above stated, exist; finally, if the two processes are in equilibrium, the child may be born mature, but comes into the world with a strongly ossified skull, and with water in its head. That this theory does not explain all cases of hernia cerebri, and that the very small ones sometimes met with, especially in the region of the anterior part of the base of the skull, can scarcely be referred to it, will be admitted; in this we need see only a proof, that the cause of hernia cerebri may be as varied in its nature as the hernia itself.

In the above discussion I have wandered rather far from my principal subject, and I now return to consider some more obvious questions, and more closely connected with it. To these belong the signification of the deficiency of skin and the radiating cicatrices, met with in the wall of the sac. These conditions occur so generally in similar tumours, as well as in

those accompanying spina-bifida (meningocele dorsi and hydromyelocele), that they have attracted a certain amount of attention, and as in these phenomena traces have been found of earlier agglutination or adhesion to one or other part of the ovum, they have been placed on a line with the adhesive formations, which commonly occur in diseases of this kind (many examples of which are to be found in the Museum of the Lying-in Institution), and must have served as the basis of the theory contended for especially by Geoffroy St. Hilaire (the elder), according to which a whole series of fœtal anomalies are to be traced to original adhesions between the fœtus and its surroundings. That the theory holds good for certain cases of acrania, hernia cerebri, anencephalia, spina-bifida, Virchow thinks (*die krankh. Geschw., p.* 176) that there is as little reason to doubt, as its invariably obtaining for all cases ought decidedly to be denied. Another question on the other hand remains, whether the defect of skin ought actually to be considered as the result of an earlier adhesion, or whether it ought not, perhaps, rather to be looked upon as a primitive lesion of formation, which in such a case could scarcely, bearing in mind the frequency of the phenomenon, be regarded as without signification for the whole morbid process. For completeness sake, I will still remark, that Meckel, who endeavoured to refer all malformations to arrests of development, was a zealous opponent of St. Hilaire's theory; for him the adhesion was in every case accidental, produced "propter magnam molem proprius ad membranas admotam."

It must not be denied that the collection of fluid often met with in the hernial sac in encephalocele and in hydro-encephalocele, may be formed and often is formed on the spot. The sac contains elements, which normally secrete fluid; this holds good not only with respect to the pial and subarachnoid spaces, but a secretion of fluid is met with, also, in the space between the arachnoid and the dura mater, though normally only in small quantity; but it is indubitable that collections of fluid may take place in this situation during fœtal life, the so-called hydrocephalus externus, which may attain to very considerable degrees, and act destructively upon the brain. When, nevertheless, I believe that in the foregoing case it is to be assumed, that the fluid at all events for the most part, is due to efflux from the interior of the brain, I do so, partly on account of the considerable amount of the collection of fluid (12 ounces), partly on account of the signs of internal hydrocephalus ensuing soon after the operation. It is, indeed, true that we had not in the reducibility of the fluid the decisive mark of a direct connection, nor did the operation exhibit rupture of the prolapsed part of the brain; but the first sign is inconstant, and the operation wound may possibly have hit upon the opening in the cerebral mass, which may thus have escaped notice. We can scarcely expect always to find so wide a communication as that mentioned in the case quoted at page 332.

I am not aware whether there is anything previously on record as to the development of hydrocephalus after the removal of a cerebral hernia; it is, perhaps, scarcely probable on account of the immediately fatal result, which has certainly followed most of the earlier operations of this kind. But of an allied form of disease, which may in many respects be compared with hernia cerebri, the so-called spina-bifida, I am in a position to adduce a completely analogous case. This is communicated by Richard de Nancy (*Maladies des enfants, p.* 30). It seems to me that no reasonable doubt can be entertained that there was in this case a direct connection between the dorsal swelling and the interior of the brain, and that the closing of the external wound was the cause of the accumulation of fluid in the ventricles of the cerebrum.

A child came into the world with a spina-bifida in the lumbar region. The infant was mature, well-formed, and sucked strongly. The spina-bifida did not present the usual appearance of a soft swelling of a red colour; it had burst during delivery, and now a reddish, roundish, surface was found, with an opening in the middle, from which a serous fluid ran in large quantity, soaking the linen. Bathing with Goulard's lotion was prescribed, and, contrary to expectation, the wound cicatrised. While this was going on it was soon observed that slight twitchings and convulsive movements in the face, and subsequently a semi-paralytic condition of the right arm took place. The fontanelles had always been large, but now the anterior fontanel especially began to rise, and 35 days after birth it projected to the size of a hen-egg. Thereupon the bones of the head commenced to separate from one another, and by degrees coma and other signs of compression came on. The cicatrix in the lumbar region remained firm and did not rise, and if it had been desired to procure the discharge of the serous fluid through it, there would certainly have been difficulty in penetrating into the medullary canal. The child's death seemed imminent, nevertheless the infant held out until the seventh month. At last the cicatrix had not been able to resist the pressure, but became arched, and showed a distinct connection between the collections in the two places.

There is one point in my report of the post-mortem examination, to which I should wish to direct attention, that is the defective state of the tentorium. It will be remembered that the middle part was entirely wanting, and with this the sinus quartus—a state of things which cannot fail to exercise a considerable influence on the regulation of the venous circulation in the brain. By affording, in the normal state, a site not only for the sinus transversus, which in this case was present, though not in its usual form, but also for the sinus quartus which again receives the blood from the interior of the brain through the vena magna galeni, the tentorium plays an important part. I did not, in the present case, succeed in clearing up the mode in which nature procured an exit for the venous blood from the interior of the brain, unless it might be through the production of the choroid plexus, which accompanied the hernia cerebri; and I would, therefore, direct the special attention of a subsequent investigator to this interesting circumstance, which, by reason of the constancy in the deficiency of the tentorium in occipital hernia, must often again occur.

In now proceeding, in conclusion, to say a few words on the subject of operation, I shall not allude to the question in general, which cannot be considered as anything definite, but must be modified according to form and other circumstances. My remarks will refer only to the foregoing case. Hydrencephalocele is looked upon, in general, as an affection which is not compatible with prolonged life, and which ought to be left to itself, as any interference can result only in accelerated death. Nélaton says that ligature, incision, and excision, are almost invariably followed by fatal symptoms; when the sac contains fluid and threatens to burst, puncture may be tried with a hope of prolonging life. Spring is quite of the same opinion: by careful puncture with fine needles, in perfectly healthy parts of the skin, we may hope to retard ulceration and rupture of the sac. Of four children, treated in this mode with repeated punctures, 2 lived two months, 2 two and a-half months, but in most cases we will be satisfied with protecting the tumour against external injury. With respect to these considerations too, my case presents no small interest. We here see the child successfully undergoing the most radical operation, the solution of continuity of the brain to be without importance, and the little patient freed from a dreadful malformation, to attain an age which it would not nearly have reached without operation, or with the aid of the above mentioned preventive means. It is, indeed, essentially to the stalked form and small bulk of the cerebral hernia, that the favourable result of the operation must be ascribed, but it certainly is due in part also to the chloroform-narcosis, and to the mode of operation selected. This was the bright side of the picture; but in every analogous case the prospect of hydrocephalus will certainly loom darkly in the background. This is, in fact, only a continuation of the morbid process which has been the starting point of the whole train of symptoms, and to arrest this in its activity, or to remedy the morbid changes which must already have been developed within the cavity of the skull to a certain height, before the occurrence of cerebral hernia, with its attending circumstances, shall have become possible, is undoubtedly beyond the limits of art. We must, therefore, hope not to be laid under the necessity of making a choice.

[It is to be regretted that Dr. Hirschsprung, in speaking of the literature of his subject, has overlooked a very valuable and interesting paper published by Dr. Robert Adams, our present distinguished University Professor of Surgery, in the first series of the *Dublin Journal of Medical and Chemical Science*, vol. i., p. 326, so long ago as the 1st of January, 1833. At that period five cases of "congenital encephalocele" had come under Dr. Adams' observation. Dr. Adams enters very fully into the literature, history, and treatment of the malformation. The drawing given in his figure 5 strongly resembles that of our author. The head, in this case, is preserved in the Museum of the Royal College of Surgeons in Ireland. In one instance the treatment by repeated acupuncture referred to by Dr. Hirschsprung, was employed with marked success.—TRANSLATOR.]

WEDNESDAY, APRIL 29, 1868.

THE POOR-LAW MEDICAL SERVICE OF ENGLAND.

THERE is no occasion to conceal our satisfaction at the approval that has been so widely expressed with the tone of our articles on Poor-law matters. The course we have adopted has been dictated by a sincere desire to benefit the poor, and to uphold the honour of the profession. It would be affectation any longer to conceal that our influence is rapidly growing, as larger circles continually recognise the honesty and independence of our motives. To those who have aided us by encouragement, advice, or information, our best thanks are due, and we trust it is unnecessary to give further pledges of our intentions. We have taken up these subjects with no other views than such as may be openly avowed. We have no ulterior purposes to serve. No undercurrents regulate the expression of our opinions. We look upon the administration of the Poor-law from an independent stand-point, and are prepared to carry out to the legitimate end the principles we have endeavoured to set forth.

The condition of those of our brethren who toil in the Poor-law service of the kingdom, has always interested us. They have ever had our ungrudging sympathy, and we trust we shall not in any case fail to urge their righteous claims. They are a section of our profession, and, inasmuch as too many of them occupy positions in which they cannot, or dare not, plead their own causes, we have the greater pleasure in speaking in their behalf. Until the profession, as a whole, finds out that it suffers with each of its members, there is little chance of its attaining the position it ought to hold. Let us then stand by each other, and do our best to help every good movement.

This evening (the 29th), at half-past seven o'clock, there is to be held at the Ship Hotel, Charing-cross, the quarterly meeting of the Metropolitan Poor-law Medical Officers' Association. The proceedings of the last quarterly meeting were fully reported in this journal, but great as was their interest, they will probably be eclipsed by what may take place to-night. The meeting will be called upon to consider, amongst other things, the proposed basis for the equalization of the salaries of the Medical Officers in the London district; the general order imposing additional duties upon Workhouse Medical Officers, and the circular respecting the employment of unqualified assistance.

But besides these questions, the importance of which will be fully recognised, the President (Dr. ROGERS) will resign his office, and as hitherto, he has had no opportunity of referring to his own case since his compulsory resignation, we may naturally expect that he will give his own version of an affair which seems likely to reflect the utmost discredit on the Poor-law Board.

Our readers are well aware that Dr. ROGERS has long been at variance with some of his guardians, and that the persons to whom he was obnoxious have at length got rid of him on a pretence, the frivolousness of which we have already exposed. As we have said before, the matter cannot rest where it is, and to-night the Association, over which he has so well presided, may be expected to consider the question and pronounce an opinion upon it. Is it to be endured that an officer, whose active exertions in the cause of humanity for a period of twelve years have endeared him to the poor committed to his care, should thus be thrust out of office without any form of trial, upon the secret accusations of his enemies in Bumbledom—and that, too, while they loudly repeat that they have no fault to find as to the discharge of his professional duties? We think the Association will have no hesitation as to the answer to be given to this question.

It ought not to be forgotten that when suspended Dr. ROGERS asked for a public inquiry, but his request, though backed by some of his guardians, was refused by the Poor-law Board. Now, why should this authority deny the forms of justice? Was it already arranged that the suspension should be converted into final dismissal? It really looks as if the Board had felt annoyed with the reminders of its duty addressed by the too zealous doctor, and weary of their continual entreaty, had resolved to grant the guardians vengeance upon their adversary. But shall the judgment of an unjust judge be suffered any longer, or shall not rather the whole community give judgment in the matter? There is, however, another explanation equally plausible, of the conduct of the Central Board. It is tolerably well-known that the Workhouse Infirmaries' Association owes its existence to the initiative of Dr. ROGERS, although others have taken up the work and pushed it in various ways, more or less commendable. Now, this Association has been the means of bringing to light things which the Poor-law Board had no desire should be known, and has increased the rapidly growing conviction that there is "Something rotten in the state of" the Board, and the department it mismanages. It is almost impossible to help feeling that this may have gone far to prejudice the Board against Dr. ROGERS, and thus stimulated to a refusal of his just demand for a public inquiry. At any rate it is clear that in refusing to hear him before condemning him, the Board, instead of being judge, takes the position of accuser.

There is yet another thought that has occurred to us in the course of the proceedings, and which we do not care to refrain from expressing. This determination to get rid of an officer who confessedly has not failed in his duty would be comprehensible if we could imagine that he might be an awkward witness in the course of future investigations, and such an idea as this would account for the dogged determination of the board to deny him the justice of a public inquiry.

But such tactics, be the motive for them what it may, will not in the end succeed.

Concealment of the truth, refusal to hear both sides, prejuding anything, is abhorrent to Englishmen, and already there are signs of resentment. Thus, the guardians who voted against Dr. ROGERS have failed to obtain their

re-election to their vestry, and we doubt not other events as significant will occur.

The nation has committed authority to the Poor-law Board that it may act justly, not that its officials may ride roughshod over the rights of the medical staff, or arbitrarily dismiss the most educated persons in its service to gratify petty vanity and spleen of the too easily irritated parochial mind. It is time to call to mind this fact, and since those who should have been first to urge it are—we write it in sorrow—silent, or worse than silent, we would repeat it in the most emphatic manner, and urge upon those of our brethren who can do so, to go to the meeting this evening and lend their countenance to the Metropolitan Association.

More than this! Our last issue contained a letter announcing that a meeting of London and Provincial Poor-law Medical Officers will be held in about a month's time. The veteran GRIFFIN from his sick-bed writes his approval, enclosing his cheque. Surely this will be a large gathering. It ought to be a mass meeting of Poor-law Medical men, and of all who sympathize with them. Every one who can will no doubt be present. But let them not wait till the day. Many arrangements have to be made, and it will greatly facilitate matters for the leaders to know in advance who may be expected. We hope, therefore, all will at once communicate with Dr. ROGERS their intention of being present, so that everything may be prepared for a triumphant demonstration.

THE PROPOSED FELLOWS' ASSOCIATION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE proposition of Mr. ERASMUS WILSON for a Fellows' Association, has received a definite shape, in his reply to our queries, published in our last week's number, and we think it is one deserving serious attention apart from the incidents of the approaching election. He would ask the Council for permission to meet in the College to discuss questions relating to the general interest. Now, this proposal brings us in presence of one of the strangest anomalies. The charter of the College makes the Fellows an elective body, and yet, that body cannot meet in its own College without the permission of the Council. Is not this a palpable absurdity? The College of Physicians is in this respect more reasonably managed. With them, the Fellows take an active part in everything. It is recognized that they are the governing body, the owners of the funds of the Corporation. They enter their College building as a right, take part in all discussions, and the youngest Fellow can exercise the privilege of the ballot. There is no doubt whatever, that the meetings of the Fellows of the College of Physicians do have an important influence, in just the way pointed out by Mr. WILSON, as that which is desirable in the sister College.

It seems to us, then, that an association of the Fellows might be a first step towards something better—say, in the first place, a recognition of the Fellows as free as that of the College of Physicians. It is monstrous to imagine that an antiquated oligarchy can any longer impose on the profession, and the College has no choice but to make extensive concessions. It is undeniable, we take it, that the elective body can control the College. The Fellows have it in their power to carry what they need. Let them put forward this plan of Mr. WILSON'S, as the very least they can accept, and elect no candidate who will not pledge himself to go as far. It would, we think, be much better, instead of forming an association, to admit that every Fellow had equal rights, and merely to insist on the Fellows' right to meet in their own building, discuss all matters relating to their College, and exercise their votes on its policy. A deliberate assembly like this could not fail to raise the standard of the College and promote the welfare of the whole profession—if once it set to work in earnest. But suppose its debates were languid and feeble, that the conservative spirit inspired its sentiments, and that Lincoln's-Inn exhibited no greater activity and life than Pall-Mall! What then? Still something would be gained—indeed much; for clearly whatever the tone of the assembly, it must, if fully attended, reflect to a large extent the opinions and feelings of this section of the profession. It would, therefore, add greatly to the social position of the college, and rescue it completely from the condition into which it has drifted under the government of a self-constituted oligarchy which cannot endure. To the Fellows then, as a body, we say, be up and doing, claim your rights as electors, place those who will support your claims in the position to aid you, insist on the rights of assembling and deliberating in your college, and having attained this, use it to promote the reforms that are so much needed.

To those who hesitate, and we are glad to know that some members of the council would have no hesitation whatever in conceding the right of meeting, we have only to say, be warned in time. The days are rapidly passing by when such moderate demands can be refused, and unless this much be gracefully and early conceded there may soon come "an ugly rush," which will sweep away all obstructives.

REPRESENTATION OF THE QUEEN'S UNIVERSITY.

OUR readers who peruse the daily newspapers, will have observed during the last few days, an account of a meeting of the newly organised Convocation of the Queen's University, and of the action taken therein respecting obtaining a representative under the provisions of the Irish Reform Bill. They will have also learned, from the answer of Lord MAYO, the difficulty attendant on granting a request which is admitted, on all hands, to be fair in itself, viz.—because doing so would involve taking away one of the seats at present apportioned to Irish Counties and Boroughs.

Notwithstanding the apparent difficulty of the case, few doubt that a seat will be given in the reformed House of Commons to a Member for the Queen's University; and hence it behoves all concerned to see without delay, who would, under all the circumstances, be the best man for the place.

It may be taken for granted, notwithstanding some loud talking to the contrary, that the constituency will not be more democratic than those of the older Universities; and that it will be mainly composed of Doctors and Masters, and of those Bachelors whose standing and years may be held to be equivalent to those required for the time-honoured degree of Master of Arts in Oxford, Cambridge, and Dublin.

Now the Doctors of Medicine are the majority; and hence arises the question—would it not be well to have a

medical man representing a constituency like this? We say, advisedly, YES; and we urge on our brethren not to promise support to a candidate arising from either of the two classes of political place-hunters, or pushing lawyers. These gentlemen are more than adequately represented in the House already. The University of Dublin has long suffered from the want of an independent member, by placing itself at the disposal of a line of lawyers, who like vastly to become M.P.'s at almost no cost, but whose zeal and ambition are uniformly extinguished as soon as they can get comfortable places. We want medical men in the House of Commons; not amateurs, but a few eminent men engaged in practice, whose position and utterances would secure them a hearing on questions with which they are specially conversant; and for want of whom we sometimes have bad legislation, and often no legislation at all. We understand that Sir DOMINIC CORRIGAN, Bart., will seek the suffrages of the electors in the event to which we refer; and, setting aside all political considerations of a party kind, with which it is not our province to interfere, we do not think a better man can be had.

Sir DOMINIC has arrived at that position in his own profession, and in general society, which will secure to the electors those advantages of which we write.

He is in independent circumstances; he wants no title, and no place; he can without much sacrifice spend a good part of the season in London; he is eloquent in address; singularly able in debate; and he is gifted with a physical power of voice which could not fail to make itself heard and felt in the House above all the cat-calls and cock-crowings of the numerous Titlebat Titmouses, the parasites of our great legislative assembly.

On the most important question of elevating our own profession by academic education, his opinions are such as commend themselves to men of all parties and schools; to men of every religion, and of no religion at all.

VISIT OF H.R.H. THE PRINCE OF WALES TO THE KING'S AND QUEEN'S COLLEGE OF PHYSICIANS.

HIS Royal Highness the Prince of Wales, accompanied by his Excellency the Marquis of Abercorn, Viscount Hamilton, Lord James Butler, Sir John M. Stewart, Bart.; Captain Stewart, R.H.A.; Sir H. Pelly, Captain J. B. J. Dormer, A.D.C.; and Dr. Minter, paid a visit to the King's and Queen's College of Physicians on the 24th instant, and was received in the hall by Dr. Churchill, the President, and the following fellows:—

Drs. Adams, Atthill, Registrar; Banks, King's Professor; Beatty, Belcher, Hon. Librarian; Sir D. J. Corrigan, Bart.; Croker, Cruise, Duncan, Dwyer, M. Eustace, Foot, Freke, Gordon, V.P.; Grattan Guinness, Rev. S. Haughton, Hayden, Head, Hudson, Jennings, Johnston, Evory Kennedy, H. Kennedy, Law, Little, Lyons, M'Cready, Moore, Ringland, Sinclair, King's Professor; Smith, King's Professor; Stokes, Professor Travers.

Preceded by the Bedel carrying the mace, and accompanied by the President,

His Royal Highness was conducted to the Council Chamber, where he viewed the portrait of Sir Patrick Dun, by Sir Godfrey Kneller; the statue of Sir Henry Marsh, by Foley; the pictures of Drs. Whitley Stokes, James Leahy, Brooke, Cheyne, Sir Edward Barry, F.R.S.; Dr. Percival, Sir Dominic Corrigan, by Catterson Smith; Dr. Mayne, &c.; the original grant of arms given in 1667, and the stained glass window, presented by Sir Dominic Corrigan when President. He was then presented with the following address:—

To his Royal Highness Albert Edward, Prince of Wales, Earl of Dublin, &c.

MAY IT PLEASE YOUR ROYAL HIGHNESS,—We, the President and Fellows of the King's and Queen's College of Physicians in Ireland, on the occasion of your Royal Highness's visit to this country, beg to offer to your Royal Highness the renewed expression of our devoted loyalty and attachment to her most gracious Majesty the Queen, and to assure your Royal Highness of the great gratification we feel that you have been graciously pleased again to honour Dublin with your presence.

We desire also most respectfully to express the great satisfaction we feel at the presence of her Royal Highness the Princess of Wales, sharing as we do most warmly in the feeling of loyalty and attachment with which all classes of our fellow-citizens have welcomed the arrival of a Princess so universally and justly beloved.

FLEETWOOD CHURCHILL, President.
LOMBE ATTHILL, Registrar.

In accordance with the rule which has been observed during the visit, the address was not read. The Prince was next conducted to the library, where he and his Excellency the Lord Lieutenant entered their names in the visitors' book.

The President, in the name of the President and Fellows then presented His Royal Highness with handsomely bound copies of the lately published memoir of the Marsh statue, and of the volume entitled, "Records of the King and Queen's College of Physicians in Ireland," compiled by T. W. Belcher, M.D., Fellow, and Hon. Librarian of the College. The royal party then left the College, and were loudly cheered on their departure.

The President wore the gold-laced cap and gown of his office; and the Fellows wore the usual (Masters of Arts) cap and gown, with the hoods of their several degrees. Such of the Fellows as had passed the Chair, also wore gold-lace tassels and bands on their caps.

Notes on Current Topics.

The Public Health.

THE return of the Registrar-General for the week ending the 18th of the present month, supplies the following figures. In London and thirteen other large towns of the United Kingdom there were registered 5038 births and 3247 deaths, the annual rate of mortality being 27 per 1000 persons living. The annual rate of mortality for that week in London was 26 per 1000; in Edinburgh 20; in Dublin 22; in Bristol 26; in Birmingham 24; in Liverpool 29; in Manchester 33; in Salford 30; in Sheffield 25; in Leeds 24; in Hull 21; in Newcastle-upon-Tyne 25, and in Glasgow 33. The births of 2453 children were registered in London, 1248 boys, and 1205 girls. In the corresponding weeks of the ten years 1858-67, the average number is 2160 corrected for increase of population. During the week there were 1539 deaths registered in London. The average number of deaths for that week, being the sixteenth of the year, is 1447, so that the death-rate was high, exceeding by 265 the number registered in the previous week.

The deaths from zymotic diseases were 311, the corrected average number being 324. Eighteen deaths from small-pox, 64 from measles, 22 from scaraltina, 8 from diphtheria, 73 from whooping-cough, 36 from fever, and 17 from diarrhœa were registered.

In the different sub-districts of the metropolis 27 deaths from measles were registered, and 12 from whooping-cough; and the deaths from fever averaged 6·2 per 10,000 of the

population, including the deaths in the London Fever Hospital.

Two hundred and seventeen deaths occurred from phthisis, 168 from bronchitis, 98 from pneumonia, 66 from diseases of the heart, and 194 from diseases of the brain and nervous system.

The deaths of three persons from intemperance, of 7 persons from burns or scalds, of 6 persons from drowning, of 8 infants from suffocation, of 7 persons who committed suicide, and of three persons who were killed by horses or carriages in the streets were registered.

Dr. Livingstone.

A LETTER was received on the 20th inst. from the enterprizing traveller by one of his friends in Edinburgh. It explains the causes of delay in his progress, and the reason why no communications have been sent by him to allay the anxiety which was necessarily felt on his behalf. The Johanna men stole away in consequence of being terrified by tales which they had heard, and left him with only nine Nassick boys. One great hindrance to him was, that the slave-traders fear the English, and avoid them. Other causes of delay were the necessity of going round the north end of the lake, the scarcity and quest for food, which led them in a zigzag direction, and rendered eight miles a-day a good march, and the excessively heavy rains. His last date is the 1st February last year when he was in Bemba, and, he thinks on the water-shed, which they were to seek in 10 degrees south latitude, and 31 degrees longitude. "The sorest grief of all," he says, "was the loss of the medicine box, which your friend at Apothecaries' Hall so kindly fitted up."

Gresham Lectures on Medicine.

THESE lectures, which have been delivered for more than three centuries, and are now, perhaps, more largely attended than ever, have during this Easter term been upon :— 1. Sleep ; 2. Pain ; 3. Nervous disorders. In accordance with the will of the founder, practical and therapeutical deductions were—as in former courses—based upon physiological and pathological data.

The state of the brain during sleep was described, of the nerves during pain, and of the nervous system in so-called functional as well as in organic derangements.

The close relation existing between states of mere mental depression—genuine hysteria and hypochondriasis, and the more chronic forms of insanity, was pointed out by the Gresham Professor (Dr. Symes Thompson), and the tendency to regard mental disorder as a special malady, having nothing in common with or due to bodily diseases, strongly reprehended.

The Medical Council.

IT is understood that this body will not meet till June 18th. We hope their debates may be of more service to the profession than has hitherto been the case. We have had plenty of talk but no practical work, unless the pharmacopœia, which was not really produced by the Council, and which might have been brought out by the same men who edited it for a tithe of the cost of the Council.

Sussex County Asylum.

THE report of the Medical Superintendent of the Sussex County Lunatic Asylum is before us. We find it as satisfactory as ever. The mortality is low, the general health good. The alterations that have been in progress ever since 1864 are now completed—enlarging the house from 450 to 710 beds. It is encouraging to see the large amount of useful work done by the patients, particulars of which are given in a series of tables forming an appendix.

Another Compulsory Resignation of a Poor-law Doctor.

THE Poor-law Board has required a medical officer of Cambridge (Dr. Ransom) to resign his post. There is no imputation on Dr. Ransom's moral character, nor upon his conduct with regard to the poor patients under his care. He has, however, had long differences with his guardians, he did not sanction certain entries in the relief-book, and—most heinous of all—he wrote a letter to a newspaper, reflecting on the guardians ! It appears that he too asked for a public inquiry, but the Board says, whatever the result of such a proceeding might be, it would not affect the decision as to the expediency of his continuing in office. Verily, Poor-law medical officers have fallen on evil days. The authorities will not be satisfied until they have driven all honest and independent men from the service. A public inquiry on the conduct of the Poor-law Board may not be far off.

Edinburgh Infirmary.

THE meeting on the 17th, which we have already referred to for the purpose of raising a fund for the re-building of the medical hospital of the Royal Infirmary was a great success. No less than £26,000 was promised that day, and something like £1000 came in daily for some time. It is pleasant to see the Royal College of Physicians of Edinburgh open the subscription with £1000. We believe that the managers of the infirmary need £40,000 in hand to commence with, and that the whole expense, including the removal of certain buildings that interfered with the ventilation was estimated at only £100,000; so that it is now pretty clear that the improvements proposed will be carried out without incurring a heavy debt. The movement is very popular. It will add to the beauty of the district as well as the comforts of the sick poor of the city.

Deficiency of Corpus Callosum.

THE *Archiv für Psychatry* (p. 128-142), mentions a case of deficient corpus callosum similar to that of Dr. Ritchie. It is one, the interesting particulars of which are published by Dr. Sander, of Berlin, in the first number of the new Berlin journal for Psychatry. The brain was in possession of Dr. Griesinger, who allowed Dr. Sander to examine and describe it. The organ had a peculiar form by the posterior lobes being widely apart, and the cerebellum thence being freely exposed to view. Some of the posterior and central convolutions were little developed. The posterior part of the corpus callosum was deficient, as the specimen was only a quarter of an inch thick, and the radiation of the corpus callosum was equally deficient, as its whole width was 3½ centimetre. The commissura mollis was absent. Dr. Sander finds the chief interest in the fact that the development of the posterior lobes corresponded to the size of corpus callosum as Reichert previously believed, and Sander adduces further proof of this from the anatomy of these parts in brains of animals. He asserts, somewhat too boldly, that evidently the deficiency was congenital, most likely owing to deficient development of blood-vessels. Sander has found ten cases in medical

literature. The patient from whom the specimen came was an idiot. Sander gives it as his opinion that idiotism is not caused by the deficiency of the corpus callosum, but of the co-existing defects. The affection cannot be diagnosed during life. Dr. Sander requests his colleagues to send him their experiences.

"Sitting at the Feet of Gamaliel."

We learn, through the medium of the *Irish Times*, that the Surgeon-Extraordinary to the Prince of Wales, the Professor of Surgery in Trinity College, the Professor of Anatomy and Chirurgery in the University of Dublin, and the University Anatomist, in common with "a large number of the principal surgeons in the city," were privileged to *attend* on the Lecturer on Surgery at Sir Patrick Dun's Hospital during an operation for excision of the knee. No doubt the principal surgeons and professors who *attend* with due diligence will receive certificates of competency to excise knee-joints. Truly, instruction never comes too late.

University of Edinburgh.—A meeting of the General Council of this University was held on the 21st, Professor Christison in the chair. It was agreed to record an expression of the great loss sustained by the University in the death of Sir David Brewster. It was also resolved to petition both Houses of Parliament in favour of granting at least two members to the Universities of Scotland. At a meeting of the Town Council of Edinburgh, also held on the 21st, the Lord Provost stated, with reference to the Principalship of the University, that the persons who had been spoken of and suggested for the office of Principal were Sir Alexander Grant, Bombay; Sir James Y. Simpson and Dr. Christison, Edinburgh; Mr. George Dawson, Principal of the Macgill College, Montreal; and Principal Tulloch, of St. Andrews. His lordship stated that the Curators had already held three meetings on the subject, and were likely to hold other two. At a meeting to be held on the 7th of May, the day for the election of Principal would be fixed. The election for the Professorship of Moral Philosophy had been appointed for the 18th of June.

Professor Roscoe will next Saturday commence a course of six lectures on spectrum analysis and its applications, at the Apothecaries' Hall, London. The lectures are to be continued each succeeding Saturday, at two P.M.

In consequence of a rifle corps having a prior claim, and unexpectedly wanting the Beaufort-house grounds on the day fixed for the medical students' athletic sports, as announced in our last, these latter will be postponed to the 11th and 12th of June.

The Jacksonian prize on the "Injuries and Diseases of the Jaws" has been conferred on Mr. C. Heath, of University College. The prize on the "Deformities resulting from Burns" was obtained by Mr. W. Johnson Smith. The triennial anatomical prize of the English College of Surgeons has not been awarded.

Dr. John Harley has resigned his lectureship at King's College. No wonder, after the treatment we have described.

The London Hospital dinner is to be held at the City Terminus Hotel, on the 6th of May, when the Right Hon. W. E. Gladstone is to occupy the chair.

The St. Thomas's Hospital old students' biennial dinner is fixed for the 21st of May, at the City Terminus Hotel. Dr. Barker is to take the chair.

The Statham Defence Fund is closed. It amounts to more than £300. To-morrow evening a meeting of the Committee is to be held, to arrange for paying over the proceeds to Mr. Statham.

Oxford is making a move in natural science. Four scholarships have been filled up in a single college. This is a step which is likely to be followed by others in the same way, and cannot fail to confer credit on Oxford.

A sum of £300 has been raised as a memorial to the late Dr. John Dickinson, who died in Africa when accompanying Bishop Mackenzie's mission. The interest is to be applied to a scholarship in the Newcastle College of Medicine where Dr. Dickinson was educated.

The papers relating to the Walsall Workhouse were to be had last Friday.

If the telegraphic information respecting the character of the injury received by his Royal Highness the Duke of Edinburgh can be depended on, the nation has to be thankful that the life of the Prince has been saved by one of the most extraordinary escapes which has ever been recorded in the history of gunshot wounds. If the ball which, we are told, entered the back half an inch from the spine, and in a downward direction, had taken the course which in nine hundred and ninety-nine cases out of every thousand it would have taken, it could not have failed to pierce the heart and great vessels, the lung, diaphragm, and intestines, or liver, such an injury to any of these viscera being almost certainly fatal. That it should have traversed a distance of twelve and a-half inches on the outside of the ninth rib, and lodged under the skin of the abdomen, without even touching the peritoneum, is all but incredible, and the fact, if true, will add another to the few extraordinary cases in which balls have glanced from their natural direction and taken a totally unexpected course. Cases are on record in which a ball entering the hip came out at the heel, where it entered the temple and passing over the bones of the head lodged at the opposite side. Mr. Lawson narrates a case in which a grain of shot striking the eye, passed from side to side under the conjunctiva; and a case was communicated to the Surgica Society of Ireland about a year ago, in which a bullet was removed from the heart of a man who received it in the battle of Salamanca thirty-three years previously.

Proceedings of Societies.

MEDICO-POLITICAL ASSOCIATION.

What may be called a mass meeting of the profession in the Midland Counties was held in Birmingham on the 17th inst. The meeting was called by the Medico-Political Association, and the chair was occupied by the President Dr. Davey. Nearly 100 new members were enrolled, so that the Midland Counties may be said to have taken up the movement most warmly, and from what transpired, it is clear that henceforth Birmingham will throw the whole weight of its influence into this Association, the objects of which are, as we have previously explained, to obtain the representation of the registered practitioner in the council, reduce the abuse of medical charities

and otherwise forward, as far as possible, every scheme for the improvement of the condition of the profession generally. The following report is a full abstract of these important proceedings :—

Mr. MACPHERSON, Local Secretary of the Association for Birmingham, said that, in the first place, 500 circulars were issued by post to the members of the profession practising in this and the neighbouring towns. To these circulars many gentlemen responded at once, by forwarding their subscriptions and enrolling themselves as members of the association. About ten days since a further issue of circulars was made. In these circulars a modification of the programme of the association was made, with a view to meet the objections of a large and influential section of the profession. The modification referred to was this : For the words "Annihilation of unpaid and underpaid hospital medical labour," the following paragraph was substituted—"A modification of the present hospital system as regards its relations to the medical profession, which relations at present press unjustly upon the general practitioners of the kingdom, not only through the abuse of medical charities by the public, but also by a universal acceptation of a principle of entirely unpaid medical labour." No sooner was this change in the programme made, than many gentlemen who had previously held aloof at once expressed their warmest sympathy with the objects of the association, and gave proof of their sympathy by becoming members of it. We have now, in this district, 85 medical practitioners who have enrolled themselves as members of the Medico-Political Association. It is little more than six weeks since the first circulars were issued, at which time few medical men in Birmingham were aware of the existence of the association—a conclusive proof that it supplies a want that has been deeply felt by the profession at large.

The PRESIDENT said they had had, as they might be aware, three meetings before that one: the first was held at Bristol, the second at Brighton, and the third, only a few days ago, at Shepton Mallet, in Somerset; and so far as they had gone they were assured that a medical political association was really needed by the profession. He believed nowhere would the expression in favour of the association be louder or more emphatic than in the great central metropolis of Birmingham. They had heard that a large number of gentlemen had already joined the association, and he had no doubt that the Birmingham physicians and surgeons would be followed by the members of the profession in other large towns up and down the country. They were desirous of promoting the interests of the profession at large, and they were desirous at the same time of promoting the public interest. They did not in any way wish to dissociate the two interests, for they believed the interests of both were bound up together. Looking at the advertisement, as it appeared in the daily papers, they would be informed of the nature and the objects of the association. The first point which doubtless struck their attention was "the representation of the registered practitioner in the Medical Council." They were quite as well aware as he was that the registered practitioner was not up to this time represented in the Medical Council. This was a state of things that could not be continued. If such a state of things did continue they were responsible for it, and they only deserved the neglect shown them. He had a higher opinion of them. If they deserved to be represented, they would insist upon being represented. They knew very well that the Medical Council, as at present constituted, represented simply the licensing bodies of the universities and the colleges. The registered practitioner was left out in the shade. This must not be, and this was one of the principle objects which they had in view. He trusted they would be able to remove so objectionable a barrier, for until the medical practitioner be represented on the Medical Council there was no hope for him. It was upon this ground, among others, that he more especially asked their support for the Medico-Political Association. Now there was a very unpleasant thing to allude to in connection with this, and that was the excessive competition that obtained in the medical profession. Let them trace this to its first cause, and he believed they would find that it arose out of the large number of licensing bodies. There were as many as nineteen licensing bodies in the profession, and what was the result? They must obtain funds somewhere, and how else could they obtain those funds but from the division of licenses to practise. A large number of young men were encouraged to go to these licensing bodies, and thus they were transmitted to the paths of the profession, and hence it was that the numbers increased so largely as they all witnessed. The result was that a large amount of unpaid and underpaid medical labour was brought into existence ; and if they went back to the first cause it would be found to exist in the large number of licensing bodies. Now, he conceived that it would be a very desirable thing, if practicable, to reduce the number of those licensing bodies, and this was one of the things they should strive for. With regard to this question of unpaid and underpaid medical labour, he said he believed the example which had been set by the members of the profession in Birmingham recently would result not only in a benefit to the profession at large, but in a gain to the public at large. They did not intend to put themselves in antagonism with the people. He would not lend himself to any means whereby the people would be deprived of the necessary amount of medical and surgical assistance. But as they were quite aware there was nothing so much abused as medical charity. They were all cognizant of the fact that a large number of persons applied at their dispensaries and their hospitals, who were not proper persons for charity. It was not at all to be supposed that medical men would submit to such a state of things. Dear me, exclaimed the President, medical men had to support themselves as well as other people! They depended on their labour as did the architect, the baker, or the butcher. They knew that in the profession there was a good deal of poverty. Those who were in the profession saw these things day by day, and they knew that the labour which was performed gratuitously for those who did not deserve it, could be discharged by the younger members of the profession. Nevertheless he hoped and believed medical men would ever be found foremost in all cases of charity, doing good where they could. What was wanted was "education ;" the people must be "educated" up to this point that they must not look for doctors to work for nothing. In his opinion, people only wanted educating up to this point. The acquirement of their knowledge as medical men was not all ; they required a great deal more to discharge their duties properly as medical men. He had an idea that the dispensaries might be properly divided into poor-law dispensaries and provident dispensaries, and he had also an idea that infirmaries and hospitals might be similarly divided. He then glanced at the proposed establishment in London of metropolitan poor-law dispensaries, and said they knew very well that they were building several large hospitals in connection with the Poor-law administration, with 500 and 600 beds in each. The carrying on of these hospitals would be undertaken by the Poor-law surgeons. A very good arrangement this would be. The statistics of the village hospitals showed the great amount of talent there was scattered over the country—talent which had never yet been brought to the surface under the pressure of circumstances. Then there was another point that struck him : if funds could be raised to support our large county and borough asylums, surely there could be no difficulty on the part of the counties and boroughs in supporting hospitals? They only wanted these things, which pressed upon the profession, modified to meet the necessities of the times. And what was another thing, the resident staff of public institutions of this kind should be larger than they were at present considered necessary. Gentlemen connected with hospitals knew very well that in consequence of the pressure upon their time by having to pass 60, 70, or may be 80 cases through their hands, it simply amounted to going in at one door and out at the other. He conceived that this was not quite what should be. He had been an hospital surgeon, and he would say that he was obliged to get rid of persons so quickly that he was not satisfied after he had passed them by. Well, this was a difficulty that was to be got rid of by an increase of the medical staff. He next referred to the Colleges of Physicians and Surgeons in Pall-Mall and Lincoln's-Inn respectively. He considered that these institutions were based upon an entirely erroneous principle : they were based on principles which obtained 350 and 400 years ago ; in fact, they were oligarchies, societies of men governed by the few to the exclusion of the many. This was not as it ought to be. If these institutions were governed upon a right principle, there would be no reason to refer to the objectionable condition of things that obtain in their profession. They might depend upon it, the College of Physicians never would alter its manners until the outsiders told the small clique that governed it that they would stand such a state of things no longer. He had been a member of the College of Physicians and Surgeons pretty nearly for thirty years, but he never had a voice in the government, and the clique would be surprised if he entered his protest against anything they decided to do. They would look upon him as a most rude and impertinent person. This

was a state of things which must be altered, and he called upon the portion of the profession he addressed to do all in their power to bring about a long-needed and a just reform.

Mr. OAKES moved the first resolution—"That this meeting pledges itself to use its best endeavours to rescue the registered practitioner from his present anomalous position with respect to the Medical Council, and to secure him a full and fair representation therein." He had great satisfaction in proposing the resolution, because he believed the general practitioners were at present suffering a serious grievance in their non-representation at the Medical Council. They had no voice in their own legislature or in the council: in fact, they had nothing which connected them with the State authorities.

Dr. LESLIE seconded the resolution, which was carried unanimously.

Mr. GAMGEE said when favoured by the executive of the association with a request that he might take some part in the movement of that day, he had very slowly given in his adhesion to the society to become one of its members, because he felt that, overworked as most of them were, he must not lightly engage in new undertakings. On looking at the programme of the association he found nothing in it that he substantially objected to; but he found that it was too one-sided to those who were taking a part in it. They complained of a grievance, and no doubt they had a perfect right to do so, and no doubt, moreover, there were grievances to complain of. But he, no more than any other man, liked a grievance-monger; and as he considered that the other side of the question was not sufficiently taken into consideration, he asked the executive to relieve him. He found, however, that those gentlemen who made out the programme intended it to be merely suggestive; that they were open to receive any modification that might be made; and that the programme had been drawn up in the view simply of eliciting, in the first place, a discussion. He therefore ventured to suggest that the third resolution—the third branch of the programme—should be modified; and, with their permission, he would read them what he suggested in its place. He suggested a resolution to this effect: "That the present hospital system requires revision in the interests of the people and the medical profession." The executive thought that that resolution was an improvement upon the previous one, and they thought that he might be doing good by proposing it. He had therefore much pleasure in moving it. When, last summer, Dr. Heslop, at the annual meeting of the British Medical Association, raised the question of the remuneration of medical officers, in a speech which for lucidity, comprehensiveness, power, close reasoning, and, at the same time, temperance of expression, could not be excelled; he (Mr. Gamgee) ventured to express an opinion that Dr. Heslop and his friends were beginning at the wrong end. He did not believe they could reform, say the legal profession, by inquiring into the conditions and the difficulties of attorneys' business. They must look at the higher courts—at the men in what were conventionally called the "higher walks of the profession." However well he understood this, they were all so much taken away by the tide of success that he threw himself into the movement, believing that the great thing was to begin. He believed that the matter had been exceedingly well conducted, and though he had only had the honour of partially taking action, he was willing to take the responsibility of the whole body. He had taken action with a part of it; he said he espoused the whole of what had been done. But he could not shut his eyes to the fact that though he knew that his friends wished well, the susceptibilities of the public had been awakened in the discussion. The people thought it rather strange that they should come forward, after so many years' silence, with a grievance which found a desire for more remuneration. They had a great deal to say for themselves, but not for the people. Personally, he thought that this was to some extent a wrong notion, but the profession was responsible to a great degree for the feeling which existed in the minds of the people. He believed that some classes of the profession more than others were responsible. He had the strongest conviction that the judgment of the mass of mankind—if it only had time for its expression, and if it only had clear reasons—was on the side of right; and if for a moment the people thought that the medical practitioners were in reality too selfish in espousing the cause of the club surgeons, this must not cause any great feeling of surprise. He thought when the plain facts were before the public, they would see that it was not a narrow policy they entered upon, that it was not a narrow view that they took of the matter, and that the partial disclosures which had been made had simply arisen from the impracticability of laying the whole of the case before the people at once. Indeed, the grievance was a great one to the club surgeons. and also to the people. The former were imperfectly paid by the people, and the latter were imperfectly served. Nobody understood this better than the people themselves, for if they asked for an article which cost £10, and insisted on only paying £7 for it, in the long run they would only succeed in getting value for the smaller amount. The time for a change had come, and he believed that there was a great central cause of the evil which existed, and that was the hospital administration of the country. He then gave a sketch of the history of hospitals, tracing the rise of clinical surgery, and remarked that it was extraordinary to notice how very recently hospitals, as at present understood, had taken up a position. Hospitals, as places for clinical instruction, only dated from the latter part of the last century; so that a complete century had not passed since they had become schools of clinical instruction. He glanced incidentally at several of the great medical and surgical reformers, some of whom had the energy of a Robespiere, and the indomitable will of a Cromwell. He next referred to the evils of hospital management, prefacing what he had to say with the remark that he did not profess to speak of all the hospitals of the country. There was a very great difference. The remarks he made applied especially to the case of Birmingham. There were two classes of hospital surgeons. In London the work was almost wholly done by honorary officers, *e.g.*, the resident house-surgeons were unpaid. In Birmingham it had been found that this was impracticable, and the house-surgeon was paid a salary. The appointment of these officers rested mainly in the committee and the medical officers; and he must say that he considered the appointments in the men were excellent ones. But as soon as the young men became appointed to those hospitals they aspired to become honorary physicians. They were elected in consequence of their scientific merit, and on their promise as young men, and they came there to work in the interest of science, and as supplementary to the honorary medical officers. If they aspired to higher positions they must be prepared with a machinery like that required at a Parliamentary election, to pay £500 down certain, that it may be supplemented with another sum almost as large; their scientific research would not be inquired into—the great question was, what were the opinions of the Governors and the subscribers, and how might they be conciliated? What a damper this was to the zeal and energy of a young man, to make him at once a Conservative and a trickster in his early days. He then referred to the amount of work thrown on hospital surgeons, some of whom had to dispose of from 80 to 120 an hour. Now, was there anything in medicine? Did these people require any attention at all? If they did not, tell them so; if they did, do not profess to dispose of them at the rate of one hundred an hour. The profession laboured under a great disadvantage because of its being a secret profession, and this had more force in the provinces than in London. He contended that practitioners should be admitted to do work in the hospitals, which was at present neglected, and he then entered into a narrative of his experience at the University College Hospital and the Royal Free Hospital, from which it appeared that very frequently those who were no objects of charity applied for and obtained that medical assistance which they were well able to pay for. He strongly condemned this system, and advised that steps for a reform in regard to it should be carefully considered. He approved of the principle of competition in the profession, on the ground that it relegated to obscurity the incompetent. Having said so much on general matters, he asked to be allowed to say something for himself. He spoke of his own connection with the hospital, and said that if he were acquainted with anyone who intended becoming a candidate for a Birmingham surgeoncy, he would ask him of the amount of his ability, and his temper. If he found that these were super-excellent, he would still not encourage him through the contest; he would ask him if his nature was made of cast-iron, and if he assured him that it was, he would then dissuade him from the contest, for cast-iron was brittle, and broke under blows. If he elicited from him that he was made from Bessemer steel, he would allow him to enter the tremendous contest, for he believed nothing else could come safely out of the process. He concluded by moving the resolution.

Mr. YATES seconded the motion.

Dr. BELL FLETCHER spoke in favour of the resolution. He said that there were abuses in their institutions was to a certain amount correct, but as an hospital physician of some

experience, he wished to say that those abuses which had been spoken of were exceptional.

The resolution was carried unanimously.

Mr. Baxter Langley then moved—"That in the opinion of this meeting the present low scale of remuneration of the Poor-law medical servants, while unjust to the medical profession, is injurious to the welfare of the sick poor."

Dr. Bell Fletcher seconded the resolution. He said he believed a great evil existed in the quarter pointed at in the resolution, and he should be glad to aid in bringing about a reform.

After a few words from Dr. Robinson, the resolution was carried, and a vote of thanks to the Chairman terminated the meeting.

MEDICAL SOCIETY OF LONDON.

April 13th, 1868.

Dr. Richardson, F.R.S., President, in the Chair.

Eleven new fellows were elected, and six new candidates proposed for election. Dr. Prosser James and Mr. Haviland were formally admitted by the President.

It was announced to the meeting that the council recommended that members of the profession resident in the provinces should be eligible for the Fellowship of the Society under the usual regulations, but on payment of the entrance fee only—the annual subscription becoming due in case of such fellow changing his residence to the area of the Metropolitan Postal district.

Mr. Francis Mason exhibited for Mr. Pratt, of Oxford-street, an artificial arm, of very ingenious construction and of moderate price, as briefly described in the last number of this journal.

Mr. Henry Lee showed the spinal cord just removed from the body of a patient, whose case was noticed at the last meeting. There existed fracture of the fifth cervical vertebra and extensive laceration of the corresponding portion of the cord, the symptoms were almost identical with those noticed in a case which occurred the very same day, in which the interior of the chora only was found bruised; but in this case there had been a herpetic eruption of the lips. The first patient, with internal disorganisation only, lived three days; the second, with fracture and laceration, seventeen days, breathing only by the diaphragm.

Mr. Bryant alluded to the question of duration of life in such cases. After a series of investigations, he came to the conclusion that when respiration became purely diaphragmatic, it was quite exceptional for a patient to live more than three or four days.

In explanation of a remark by Dr. Day, Mr. Lee said that he considered the herpetic eruption possibly due to some absorption from the fractured cancellous structure of the bone.

Mr. Hunt drew attention to the use of nitrous oxide as an anæsthetic, which had been suddenly urged upon the profession.

The President considered that nitrous oxide was no true anæsthetic, but an asphyxiating agent. It does not diffuse into the blood, but prevents the normal oxygenations; its action upon animals is rapidly fatal. It cannot be otherwise than a dangerous agent, and its employment a retrogression in science.

Mr. Henry Lee asked why those agents which merely prevent or withhold oxygenation, can of themselves prove fatal?

Dr. Sansom greatly agreed with the President; nitrous oxide had been formerly tried and found wanting, it was an asphyxiating agent, and no asphyxiating agent can be a mere negative, for whenever there is a deficient oxygenation of blood, there is always accumulation of the products of disintegration, which are in themselves deadly poisons. Nitrous oxide is greatly inferior to chloroform, both as to its manageability and its prospects of safety.

Dr. Broadbent having postponed to a future meeting the discussion on his exceptions to the propositions on Force,

Mr. Thomas Bryant read the first paper of the evening—"On some cases of inflammation of the breast simulating cancer." The author related ten cases in which many of the local symptoms could have led to a wrong diagnosis, had the surgeon failed to inquire into the previous history and causation of the signs observed. In some the retracted nipple had been congenital, in others adherence or puckering of the skin over the breast was the result of a previous abscess. The value of an exploring puncture in doubtful cases was illustrative. Nearly every local sign of cancer may be simulated by some simple affection, and it is only by careful attention to small points that a true diagnosis may be made.

Mr. Francis Mason had known instances of subgrowths from the perichondrium or periostium of the ribs, which simulated the appearance of cancer.

Mr. Henry Lee said it was important in all cases to distinguish between real retraction of the nipple, and encroachment of the neighbouring structures thereupon.

Mr. Spencer Watson related a case in which some signs indicated cancer, others abscess; there was even on the surface of the tumour a spot which plainly gave fluctuation of subjacent pus: yet the breast having been removed, the centre of the tumour was found to be decidedly cancerous.

Mr. Hunt and Dr. Gibson also took part in the discussion, and related instances of difficult diagnosis.

In his reply, the author explained the mechanism of retracted nipples, it is merely the result of the reparation of the milk-ducts by an exudation occurring between them.

Owing to the lateness of the hour, the paper on "Hospitals," by Dr. Oppert, which had been announced, was postponed till the next meeting.

SURGICAL SOCIETY OF IRELAND.

27th March, 1868.

Mr. Porter, Vice-President of the College, in the Chair.

FRACTURE OF BASE OF SKULL.

Professor Morgan exhibited the skull and lower-jaw of a man, who jumped out of a window on the previous Saturday morning, fell from a height of 55 feet, and died on Monday evening, from the injuries he had received. He was brought into hospital immediately after the occurrence of the accident, and seemed to have, not so much symptoms of compression, as symptoms of inflammation of the brain. They were somewhat puzzled at first by the case. The man had fracture of the anterior part of the base of the skull, running down from the ethmoid bone—the nasal bones and the ethmoid bones were broken into several fragments. On opening the skull the first thing that struck them was, that it was a remarkably thin one. The naturally thin portions were as thin as paper. The dura mater was found to be adherent to the skull, and when it was raised, there was a large quantity of pus found underneath it. The pus was chiefly on the upper part of the anterior lobes; there was comparatively little on the lower part. The point of interest in this case was, whether the pus was the result of the injuries, or the result of the previous inflammation that led the man to take the dangerous leap. The only information received of the history of the case was, that the man had been under the care of Mr. Colles, in Steevens' Hospital, up to Thursday week last, when he was removed to his own home. On Thursday he was somewhat excited; on Friday he was delirious, so much so that his friends watched him. On Saturday morning, when their attention was momentarily relaxed, he suddenly rushed to the window, leaned over the sash, and came out. It was supposed he fell on the signboard, and was then thrown forward on his face on the flagway. The question, as he had already observed, was whether the pus on the upper surface of the brain was the result of the previous inflammation, or had been caused by the injuries received by the fall. When they raised up the anterior lobes and examined them, there seemed to have been a loss of substance, probably caused by a bulging of the ethmoid. The pus was of that greenish colour seen in those cases of cerebro-spinal meningitis, with which they were latterly so familiar. There were some adhesions between the dura mater and the surface of the brain. There was no localized abscess that he could detect, but he had not opened the brain, not wishing to spoil the specimen. At the same time the man got fracture of the lower jaw. It was a specimen of fracture just at the symphysis, in an adult, the man being 40 years of age. He had extensive ecchymosis and swelling of the eyelids. He was not, strictly speaking, insensible. His surface was warm, and he had no signs of compression of the brain.

GENERAL EMPHYSEMA FROM RUPTURED LUNG.

By E. D. Mapother.

Surgeon to St. Vincent's Hospital, &c.

I propose to relate briefly the following case of emphysema from ruptured lung, and then to comment on the circumstances which conduce to that pathological occurrence. On the 29th of February, Eliza Farrell, aged two years, a healthy child,

had a fall, her chin coming against a stool. No local injury resulted, but the child being greatly frightened, seemed to cease breathing for a moment or two, and then screamed violently. When the mother took her up she perceived a swelling above each collar-bone, which gradually spread to the surface of the chest, neck, and eyelids. When admitted into St. Vincent's Hospital, 36 hours after, these parts were tensely emphysematous; there was neither fractured rib nor clavicle, nor any other injury, the skin of the chin, where it was said the blow was received, not being ecchymosed. There was no difficulty of breathing or cough. I conceived that a forcible inspiration occurred after the fall, and that the air-cells near the root of the lungs being thus distended, were burst by the sobbing and crying movements, which are expirations with the glottis closed. The air was then pumped into the posterior mediastinum, and thence towards the skin. In anticipation of pulmonary inflammation, I gave a little grey powder, and to lessen expiratory force and prevent further inflation of the areolar tissue, I put a bandage round the chest. The air gradually passed away, and on the seventh day after the accident, the child was in perfect health.

The following points seem worth discussing:—

1st. The rupturing force has been the retarded expiration in cases of whooping-cough, foreign bodies in bronchi, a sudden cry or laugh, loud speaking (as occurred in the case of a barrister while pleading), primiparous labour, hysteria, and during the reduction of a dislocated humerus. In all such instances there is a full inspiration, and the expiratory movements are most forcible, but the exit of air is not free. Rupture of air-cells usually occurs in the difficult expirations of animals in whom the pneumogastric nerves are cut, the laryngeal muscles becoming so flaccid that the arytenoid cartilages fall together, and it is probable that in whooping-cough (which is the most frequent cause of this kind of emphysema) these nerves are functionally disordered.

2nd. The air-cells near the root alone rupture, because elsewhere the lung is firmly enveloped in pleura, and the elastic subpleural layer described by Stokes. In the bladder the serous part is far more apt to burst than the non-serous. The funnel shape of the terminations of the bronchi tends to confine the air, and the air-cells at the very end more readily give way, as those along the sides are supported by other infundibula. During violent expirations, as we see during a fit of coughing, the lungs yield most at their upper part, bulging outwards above and below the collar-bones, but this is the part of the organ least accustomed to distension in ordinary breathing. There is no compression offered by the spine, for it is fixed, nor by the cervico-thoracic septum, for, notwithstanding the expansion it gets from the anterior scalenus it is yielding. The right lung would probably give way more easily, as its root is higher up, and the liver firmly resists below, but more than two-thirds of the pleural ruptures in cases of pneumo-thorax have been on the left.

3rd. Out of 38 such recorded cases which I have analysed, 34 were in children under four years. At that period the average weight of both lungs is seven ounces, whereas it is six times as much in the adult. These organs rapidly expand from their fœtal state, so that the air-cells, which are about 1-250th of an inch at birth, are soon twice that size, their walls being softer and thinner than in the adult. The upper part of the chest in children undergoes the most vigorous movements, and, considering the need for abundant aëration, the respiratory force is several times more powerful in proportion to weight and height than in the adult. In the child the interlobular areolar tissue is extremely fine, and there is little fat in the posterior mediastinum, and the air easily makes its way to the subcutaneous layer, but there from the abundant fat it meets resistance, and the emphysema is rarely very extensive. For the above reasons it is easy to burst the infant lung, and insufflation is said to be an occasional mode of infanticide in France. When removed from the chest the lungs bear a much greater expanding force without rupturing, as there is not unequal resistance. Children more frequently cry violently, and are more subject to spasmodic cough than adults, and hence again their greater proneness to this form of emphysema. Whooping-cough is the most frequent cause, and Mr. Richardson has given us an opportunity this evening of examining both a dried and a microscopic specimen of interlobular emphysema so produced. As that epidemic has been most prevalent during the past year, some of our members may have met with this complication.

4th. General emphysema is to be explained only by a rupture of some hollow viscus, for the inflation of the areolar tissue with gases evolved by decomposition has not been proved, on reliable evidence, to extend beyond the gangrenous part. Inspector-General Monat, in 1839, reported a case of rapid gangrene in India, in which two hours after death emphysema became general, but decomposition in that climate is ten times as fast as in this. The gases which are emitted by putrefaction are inflammable, as may be tested by puncturing the skin of a corpse which has been for many days floating in water, and if they were generated during life one might believe even in spontaneous combustion.

While the serum which moistens the areolar tissue, or that poured out into the pleura in hydro-thorax could only emit gases by decomposition, the blood which had them dissolved may possibly do so.

Dr. Graves recorded a unique case of emphysema after excessive bleeding, in which the air seemed to escape from the blood, owing to diminished pressure, and then to permeate the areolar tissue of the body. With this exception, I can find no instance of general emphysema in which there was not evidence of rupture of the respiratory or digestive passages, on both of which the expiratory movements would act so as to express the air or intestinal flatus.

A case is recorded by Holmes, in which, after rectal puncture of the bladder, flatus was diffused through the areolar tissue as far as the surface of the chest, and Haller observed general emphysema to result from meteorismus, the intestine giving way as far as the subserous coat into which the air was forced. The latter occurrence has been often observed in cattle when the paunch has been over-distended by flatulent food.

William Hunter notes that general emphysema was frequent in the cattle plague of last century, and it occurred in half the cases of the late epidemic, more especially in young animals. It is due to the sudden and violent groaning expirations of the creature bursting the lung, the due exit of air being obstructed by the swelling of the tracheal and laryngeal membranes. In the ox the interlobular areolar tissue is very loose, hence the great effusion of lymph which results in pleuro-pneumonia, while the sub-pleural elastic layer is very strong—anatomical reasons which account for the occurrence of interlobular instead of vesicular emphysema in that animal. Mr. Ferguson lately asked me to witness a post-mortem on a horse which had died with universal emphysema, due, it was thought, to some septic condition, for the occurrence of any injury was denied. However, it was found that a rib had been broken, probably by a kick from a brutal groom.

In the pathological part of my Student's Manual I have inserted a woodcut of a case which was recorded as one of spontaneous effusion of air, but I believe it to have been similar to the one now detailed.

Authors talk of the secretion of air into the peritoneum, into the stomach, and into the womb; as regards the first we have no proof that air ever distends that sac, and it is more probable that the stomach becomes inflated by fermentation of food, and the womb by suction of air through the vagina. Surgical writers have appealed to the swimming bladder of fishes as a sac into which air is secreted, but they forgot that that organ always communicates at some period of life with the alimentary canal.

Emphysema from ruptured lung has proved occasionally fatal, and in such cases the mediastinum has been found so greatly distended, and so much air effused under the pulmonary pleura, that apnœa should result.

Lastly, as to treatment. Puncturing the skin and bandaging the chest are the surgical steps which seem advisable in cases in which respiration is impeded. William Hunter first advised puncturing the skin, having learned its efficacy in cases of cattle plague. The mediastinum and interlobular spaces must be relieved accordingly as the air fizzes through the punctures, and the free passage of air, which has been rendered less irritating by being respired, produces no ill effect upon the areolar tissue.

A bandage round the chest is useful in lessening the expiratory force, but if there was much compression of the lung previously, it would be unendurable.

In such cases the sac of the pleura does not contain air. Halliday records a case in which a vomica burst both into the mediastinum and left lung, immense subcutaneous emphysema resulting. The dyspnœa was so great that it was resolved to tap the chest, but the emphysema prevented the surgeon from making sure on which side the pneumo-thorax was. The sound side was chanced on, and the patient was suffocated in a few minutes from collapse of both lungs.

It was Hewson who first asserted that pneumo-thorax and

compression of the lung must precede the escape of air into the subcutaneous areolar tissue in cases of fractured rib. Professor Porter, in his lectures in this college in 1839, advanced another theory, which, although I believe the correct one, has not attracted attention. He argued that emphysema only occurred in cases where adhesions between the pleural surfaces had kept the wound in the lung and the wound in the chest in correspondence. In rabbits or dogs with healthy lungs Hewson was never able to produce emphysema by any kind of wound. Many cases of wounds of the lung from broken rib are not attended by emphysema, because the required adhesions are not present, and such cases are not followed by great difficulty of breathing, nor invariably by death, as they would be if pneumo-thorax was a necessary part of the case.

The question is most important, for if there be air in the pleural sac producing dyspnœa, it should be removed with a trocar and canula, a long tube and stop-cock being adopted to the latter to prevent admission of air. The external wound will be readily closed with sutures and collodion, and as wounds of the lung heal rapidly, air will not be again expressed into the pleural sac. The quantity of air the pleura will contain is surprising. Dr. John Davy removed by tapping the right pleura of a young soldier, 225 cubic inches of gas, 92 per cent. of which was nitrogen, and 8 carbonic acid, the oxygen having been removed by respiration.

In cases of fractured rib, especially if the lung be torn, it would be very desirable to compress the injured side, and yet leave the sound side free. I think this might be done by rolling the bandage round the arm of the sound side, the limb being kept out from the ribs by large pads placed between the elbow and the ilium. The bandage might be also carried from the ribs of the injured side round the neck and shoulder and pelvis of the opposite side, which would leave the ribs free to move. The ribs would be then raised and everted by the muscles on the side which was not compressed by the bandage. Placing the patient on the injured side tends to the same end.

I understand that Mr. Macnamara has lately met with two cases similar to that I have recorded, and I trust he will relate them to the society.

The CHAIRMAN was sure the meeting would agree with him in thinking Professor Mapother's paper a most interesting one, not only interesting in respect to the affection itself, but as regards the treatment.

Professor MACNAMARA said he had had a couple of cases recently, of the character of the cases which Professor Mapother had brought before them. One of them was the case of a little child, three years of age, who had fallen down a flight of stairs, and was brought to the Meath Hospital, presenting an emphysematous appearance, such as Professor Mapother had described. It was also on the left side, and on making inquiry from the resident pupil he was told that it appeared immediately at the upper portion of the left side of the clavicle, and from that he at once predicted that there was no fracture. On careful examination of the little patient, this proved to be perfectly correct. It was exactly the form of injury Dr. Mapother had so well described, caused by the child holding its breath on falling, and then screaming and rupturing the air-cells. He had no trouble with the case—the patient getting rapidly better. As to the mode of bandaging when the injury was caused by fracture of the ribs, he was in the habit of treating the case differently from the mode mentioned by Dr. Mapother. He used broad bands of sticking-plaster, extending from the spine posteriorly to the centre of the chest anteriorly, securing the ribs on one side perfectly and having the ribs on the other side quite free. He had been exceedingly satisfied with this treatment and he had induced the pupils at the hospital to adopt it in all cases of the kind which came under their care. They had informed him that the result was most satisfactory. He did not take the slightest credit for originality in adopting this treatment. He did not know by whom it was first suggested. About a couple of years ago, he had the honour of being consulted by letter, as to a very curious and rare case of emphysema occurring during delivery; and it so happened that Dr. Pratt, the gentleman by whom he was consulted, was present that evening, and if he mentioned the particulars of the case he was sure it would interest the society greatly.

Dr. PRATT said that if he had had the slightest notion that the subject of emphysema would be brought forward that evening, he would have brought with him the notes of the case referred to by Professor Macnamara. He was called on to attend a farmer's wife, a handsome, strong, healthy, young woman, 26 years of age. The labour was not a very tedious one. He saw her about the second stage of the labour. As it progressed she complained of difficult breathing, which astonished him greatly. She said, "doctor I am getting worse;" and he perceived that her chest was puffed out like a bladder—the swelling went up to the neck, stopped along the margin of the chin, and the back of the neck. Her body was swollen in a like manner. The child was born, and then she said she felt better, which was to be expected, as she obtained more breathing room. This was the case about which he had consulted Dr. Macnamara. The only treatment he had recourse to was, along with the usual bandages, to get the ordinary stays, worn by women, and lace them tightly from above downwards. She got well in four or five days. She had three children since without a recurrence of emphysema. The libraries in the country did not afford much facility for examining into the records of medical cases; but he had since ascertained that cases of this kind are mentioned in Copeland's Dictionary.

Dr. FLEMING observed that, as they were all aware, many cases occurred in which it was impossible to tolerate the presence of any bandage, no matter how applied. As to the special application of the strapping referred to, he had used it, and it was especially recommended by Mr. Hilton in his lectures, and he at first thought it was adopted at his (Mr. Hilton's) suggestion. He understood, however, it was alluded to in the translation of Malgaine's work, introduced probably by the translator, as it was not in the original French. The occurrence of emphysema was familiar to every surgeon, and also emphysema complicated with pneumo-thorax. He would say, as regards the use of the bandage, that he would be influenced by the effect produced on the patient as regards relieving pain or respiration, should dyspnœa exist. As to the application of strapping, he had found it most satisfactory in every case in which he had had recourse to it.

Mr. H. G. CROLY said that eight or nine years ago he read a paper on the rupture of the urinary bladder, which took place in the City of Dublin Hospital, when he was its house-surgeon, and Mr. Tufnell kindly allowed him to show the specimen. There was fracture of the pelvis, fracture of the pubis, and well-marked emphysematous crackling in the abdomen. The late Professor Power thought that the emphysema must have arisen from the entrance of the air into the catheter, while others thought it must have been due to the decomposition of the blood. He (Mr. Croly) never adopted any other plan than that of strapping the side with broad bands of sticking-plaster, and it appeared to answer much better than the ordinary bandage.

Mr. RICHARDSON said the specimen under the microscope and that in the jar, alluded to by Dr. Mapother, were taken from the lung of a child, two years and a-half old, who died in the South Union Workhouse some years ago; the emphysema occurred during a violent fit of whooping-cough. The air-cells are much dilated in both the microscopic and the dry, specimens. The microscopic section is stained with carmine to render its structure more visible.

Dr. H. KENNEDY said he had seen one instance of spontaneous emphysema in the adult. The patient was a lunatic, and all that was known about him was, that he had wasted very much. In this state emphysema suddenly appeared, and spread over the whole body, except the scalp, palms of the hands, and soles of the feet. The patient died, and on examination a mass of disease, of the strumous character, was found in the posterior mediastinum. At one part an abscess had formed, which seemed to communicate with the root of the left lung; and, in this way, the emphysema had formed. Before sitting down, Dr. K. wished to allude to a point incidently spoken of by Professor Mapother. He meant the use of the common grey powder, the mercury with chalk. On two occasions, in which he had lately used it with children, the effects were very severe; and yet the dose was only a grain, which, however, caused very severe and instantaneous vomiting. On referring to his friends, Drs. Grimshaw and Reynolds, he was told that, in the preparation of the medicine, an active salt of mercury was frequently formed. Besides this, he had read that arsenic was occasionally found in it. Dr. K. thought the point one of moment, and worth bringing before the Society.

Professor HARGRAVE observed that there must have been some idiosyncrasy in the case mentioned by Dr. Kennedy to render the use of the grey powder so irritating. He himself knew two families, none of the members of which could bear the hydcum creta. He had to change from that to the mercury with magnesia, which agreed with these two families in the most satisfactory and effective manner. This was well-known by the families, and when another doctor was called in,

they informed him of the peculiarity. As to the use of bandages, he was not aware that strapping for fractures of the ribs was first used by Mr. Hilton. As far as his information went, it was first tried in the Crimea, and some very practical papers had appeared in the Scottish journals in reference to this and other subjects by Mr. M'Leod. Very few patients could bear the circular bandage, and the principle of this improved method was the laying on of the plaster diagonally. It was a most valuable improvement on the treatment of fractured ribs. He was told there was an unfortunate practice prevailing in the army department, by which these gentlemen were not allowed to publish anything until they submitted it to the authorities, and he thought the authorities were greatly in error in placing such restrictions on the communication of information calculated to advance medical and surgical science.

Professor MAPOTHER said Dr. Kennedy's observations reminded him that he should have stated that in Dr. Mouatt's case, the emphysema was chiefly remarked on the scalp, which showed that it was not emphysema that had occurred during life.

(To be continued.)

DUBLIN OBSTETRICAL SOCIETY.

SEVENTH MEETING.[1]

THE Society met in the hall of the College of Physicians, on Saturday, 11th April,

Dr. HARDY, President, in the Chair.

The minutes of the last meeting were read and signed.

Dr. KIDD, Hon. Secretary, read a letter from Professor Harley, of University College, London, presenting to the Society a photograph of a youth now in his sixteenth year, who had been extracted from the uterus of his mother immediately after her death, when she was seven and a-half months pregnant. When Dr. Harley was house-surgeon to the Edinburgh Maternity, he was called to one of the patients who was in a state apparently of suffocation; failing to relieve her otherwise, Dr. Harley performed tracheotomy, but the woman died in a few minutes, whereupon he at once performed the Cesarean section, and extracted this boy, who is now a page in his service.

On examination, the woman was found to have been suffering from extreme narrowing of the mitral orifice of the heart and permenent patency of the aortic valves.

Dr. BEATTY read a "Case of Enormous Fibro-cystic Tumour of the Vagina" removed by operation, and exhibited the specimen.

The patient, aged 42 years, was admitted into the City of Dublin Hospital in August last. She was blanched and nearly pulseless, and very feeble from continued hæmorrhage from the vagina. Examination disclosed an immense fleshy mass, filling the whole vagina so completely that its attachment could not be made out even with the assistance of chloroform, whereby first Dr. Beatty and then Dr. Kidd got their hands successively into the vagina, but neither could reach any neck or attachment. Neither excision nor ecraseur could be employed, and with great difficulty a ligature was cast round, as high up as could be reached by the double canula of Gooch, and in eight days the tumour was cut through. There was delay and difficulty in its extraction, and the following day it was expelled from the vagina, of great size, and partaking of the fibro-cellular character. The source of its growth was then seen to be from the upper and left side of the vagina, a raw surface about the size of a half-crown piece pointing out its attachment.

The patient left the hospital well in three weeks.

Dr. Beatty exhibited the very large tumour, which had been admirably preserved in a solution of carbolic acid.

Mr. R. W. HARLEY detailed a case in which he had treated a man for gonorrhœa, and soon afterwards attended his wife in her confinement. On the second day the woman got effusion into the elbow-wrist and ankle-joints with great pain, which he treated as gonorrhœal rheumatism, and she made a good recovery, though tedious. The child also became affected with purulent ophthalmia. Mr. Harley briefly drew attention to the concurrence of gonorrhœa in the father, rheumatism in the mother, and purulent ophthalmia in the child, and also to the difficulty of distinguishing rheumatism occurring soon after delivery from puerperal arthritis.

Dr. MACDONALD, Professor of Natural History of St. Andrews, communicated to the society some views he has been recently led to entertain, as to the course of the circulation in the fœtus. He argued that the blood was carried from the placenta to the child by the umbilical arteries, and returned to the placenta by the umbilical veins, and illustrated his views by observations in comparative anatomy and in embryology.

Dr. MCCLINTOCK moved, and Dr. CHURCHILL seconded, a vote of thanks to Professor Macdonald for his communication.

VISIT OF H.R.H. THE PRINCE OF WALES TO THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

His Royal Highness, attended by Major-General Knollys, the Earl of Mayo, Viscount Hamilton, Lord Henry Lennox, Dr. Minter, Surgeon-Extraordinary to his Royal Highness; and Captain Stuart, A.D.C., visited the College by appointment on Wednesday last, and was received by Mr. Adams, the President and Surgeon to the Queen in Ireland; Mr. Porter, Vice-President; and the following Councillors:—Mr. Hargrave, Mr. Collis, Mr. Irvine, Dr. Barker, Dr. Wilmot, Mr. Macnamara, Dr. Labatt, Dr. M'Dowel, Mr. Ledwich, Mr. Jameson, Dr. Carte, Dr. Wharton, Dr. Hatchell, Dr. A. Walsh, Dr. Mapother, Dr. Elliott, Dr. A. H. Jacob, and Mr. Hughes, Secretary of Council. The following Examiners were also present:—Mr. Fleming, Mr. Stapleton, Mr. Richardson, Mr. Stoker, Mr. Tufnell, Dr. Barker, Mr. O'Grady, Dr. Quinan, Dr. Isdell, Dr. Cronyn, Dr. Byrne, Dr. Murray, Dr. Shaw, Professors Benson, Minchin, and Bevan, Mr. H. G. Croly, and Dr. Hewitt.

The Prince was conducted to the Albert Hall, where the memorial bust of His Royal Highness the Prince Consort was inspected by him. His Royal Highness then visited the Museum, under the guidance of Dr. John Barker, the Curator; and having inspected the Board-room, with its celebrated portraits of Hawthorne, Rennie, Colles, and Jacob, and the library, where some rare Egyptian illustrations attracted his attention, and were explained to His Royal Highness by Dr. Jacob, retired to his carriage.

Medical News.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—Since 1st January last the following gentlemen have passed the First Examination of the Faculty :—

Thomas Bebbington, Liverpool; Thomas Blackton, Galway; Joseph Highum, Glasgow; John T. Jones, Glasgow; Albert B. Lauder. Glasgow; Bernard J. Lee, London; Patrick M'Court, Glasgow; Edward O'Reilly, Dublin; George Stevens, London; Henry W. Toyne, Dublin; James F. Wharton, Glasgow: James W. Wilson, Glasgow.

During the same period the following gentlemen have passed the final examination of the Faculty :—

Thomas W. Blackton, Galway; Theobald Bryson, Glasgow; Patrick H. Burke, Dublin; Clifford Crewe, London; George M'Lean, Glasgow; S. J. Moore, Glasgow; Charles O'Doherty, Glasgow; Albert Ryan, Dublin; A. W. Smith, Glasgow; Albert J. Watson, Dublin.

The following gentlemen have passed the First Examination for the Double Qualification, granted conjointly with the Royal College of Physicians of Edinburgh :—

John M. Cuthbertson, Glasgow; Robert Davis, Glasgow; John Leckie, Glasgow; Robert H. Owen, Glasgow; Evan Powel, Glasgow; John L. Reid, Glasgow; William L. Roberts, Glasgow; William C. Thomson, Glasgow.

The following gentlemen have passed the Final Examination for the Double Qualification :—

Hugh W. Arbuckle, Glasgow; George R. Atkenson, Glasgow; James G. Beasley Glasgow; John Jones, Glasgow; Silvester Marsh, Manchester; James Robertson, Glasgow; William Stephen, Glasgow.

UNIVERSITY OF CAMBRIDGE.—The following report of the Board of Medical Studies was issued on the 22nd:—"The Board, having taken into consideration the requirements for admission to the degree of M.D., are of opinion that it would be advantageous to make some change in them, for

1 The papers will be published in full in the *Dublin Quarterly Journal of Medical Science.*

the following among other reasons :—That whereas at present the degree of M.B. and M.D.—on a level as far as conferring the right to practise as a physician is concerned—represent a difference of academical status only, the degree of M.D. if obtained by further and somewhat higher tests of qualification, would entitle the Doctor of Medicine to be considered as holding legitimately and substantially a position in the profession superior to that of the Bachelor of Medicine. The Board therefore recommend that, previously to the thesis being read, four topics, relating severally to physiology, pathology, practice of medicine, and state medicine, be submitted to the candidate, on one of which, selected by himself, he should be required to write a short *extempore* essay. That the *viva voce* discussion and examination in the act be somewhat extended in length, but restricted to the subjects of pathology, practice of medicine, and state medicine, and the subjects of the thesis and essay. That the assessor assist the Professor in choosing the four topics and in deciding on the merits of the essay, as well as in conducting the act. That the thesis be sent to the Regius Professor at least a fortnight before the time for keeping the act; and, after the act is kept, the thesis, or a copy of it, remain in the custody of the Professor."

CARMICHAEL PRIZES.—The successful competitors for the Carmichael Prizes are to be publicly announced, and portions of their essays are to be read in the theatre of the Royal College of Surgeons on Monday next at three o'clock. The Fellows of the College are specially summoned, and licentiates and medical students are also invited to be present.

SESSIONAL ARRANGEMENTS IN THE DUBLIN SCHOOLS.—We understand that a meeting of all the gentlemen connected with medical teaching during the winter session has been summoned to consider the expediency of opening the session on the 1st of October instead of the 1st of November. The time and place fixed on are Tuesday the 5th of May at four o'clock at the Royal College of Surgeons. We trust there will be a full attendance, so that the question may be fairly and fully discussed.

THE operating days at Royal Free Hospital have been changed to Tuesday at nine A.M., and Friday at 1·30 P.M.

VISIT OF THE PRINCE OF WALES TO DUBLIN HOSPITALS.

ON Friday the Prince and Princess visited the Mater Misericordiæ Hospital, and was received amongst others by His Eminence Cardinal Cullen, the Right Hon. Judge O'Brien, Right Hon. Judge O'Hagan, the Right Hon. the Chief Baron, Sir Wm. Wilde, Sir Bernard Burke, Sir James Power, Bart., M.P.; V. O'B. O'Connor, D.L.; Alderman Campbell, J.P.; the Right Hon. Mr. Cogan, M.P.; Sir John Hogan, M.P.; Dr. Hughes, Dr. Griffin, J. Lentaigne, Inspector-General of Prisons, Dr. Tyrrell. The illustrious visitors proceeded through the various wards of the hospital, and on returning to the reception room, the following address was presented to the Prince of Wales by Cardinal Cullen :—

"To his Royal Highness Albert Edward, Prince of Wales, Earl of Dublin. May it please your Royal Highness—We, the council and medical faculty of the Mater Misericordiæ Hospital, humbly approach your Royal Highness, and beg to express our joy that this, your auspicious visit to this institution, affords us the opportunity of mingling our voices with those of our fellow-citizens, who during the past days displayed such unanimity and concord in welcoming your Royal Highness and your illustrious Consort to the Irish shores. Whilst we sincerely trust that this, your visit to Ireland, may be the harbinger of a new and prosperous era to our country, we cordially pray that your Royal Highness and your illustrious Consort may enjoy many years of prosperity.—We have the honour to remain your Royal Highness's faithful servants."

Driving to the Adelaide Hospital, the illustrious visitors were received by the Board, including the Rev. Mr. Plunkett, Mr. George Woods Maunsell, Dr. Law, Dr. Duncan, Dr. Head, Dr. Little, Dr. Walsh, Dr. Macalister, Dr. Barton, Dr. Richardson, Dr. Smith, and Mr. Kenyon. The matron, Mrs. Russell, conducted the Royal party through the children's ward and day ward. Entering the board-room an address was presented to the Royal pair, who shortly after departed. Subsequently a vote of thanks was passed to their Royal Highnesses for their visit.

NOTICES TO CORRESPONDENTS.

A. B.—You will find a full report in the present issue.

W. M. R.—See leader this week. It is impossible to print your letter, although we confess that your indignation is by no means uncalled for. The conduct you denounce is certainly "infamous," but then you apply epithets to persons which are too strong for publication.

DR. WILSON.—Next week.

Correspondents who have kindly sent us the following newspapers with medical items marked will please accept our thanks. Many we are unable to notice owing to pressure on our space. The Somerset and Wilts Journal. The Oxford Times. The Razor. The Birmingham Daily Gazette. The Brighton Gazette. Worcester Journal. The Spectator, &c.

DR. WILSON.—The views of Dr. Symonds on headache were given in the Gulstonian Lectures for 1853, before the College of Physicians.

Letters have been received from R. G. Watts, M.D.; N. J. Butler; A Poor-law Doctor; W. B. Herapath, and T. M. Dalon, but are unavoidably postponed until our next.

UNQUALIFIED ASSISTANTS.

T. F. takes some exception to our remarks last week on Unqualified Assistants. In stating the case as it is in England and Ireland we merely drew attention to the facts.

Several other correspondents write upon this subject, and especially as to Poor-law Medical Officers. The following paragraph from one important letter embodies the pith of the remarks of several of our correspondents:—

"Of course no man would be fairly entitled to work by deputy (ordinarily) if he had no more work than he could do himself, and if the work were so well paid that he could afford to do it all personally, and even under existing circumstances when (contrary to law) he is so often in possession of a district far too large or too populous, no objection could be made to the recommendation that he should employ a *qualified* assistant only, provided he were paid a sufficient salary. But how if he must employ an assistant and if his salary won't pay the cost of a qualified man?"

VACANCY.

Medical Officer of Bandon Dispensary District, Bandon Union, H.B. Onuston, M.D., deceased.

MARRIAGE.

M'CLOSKEY—CALFERTY.—In the Catholic Church of Londonderry, on April 21st, by the Rev. Michael Tracy, C.C., assisted by the Very Rev. Dr. Devlin, V.G., Strabane, and the Rev. F. Kelly, C.C., Castlederg, Joseph R. M'Closkey, M.D., Strabane, to Rachel Maria, only daughter of John T. Calferty, Esq., Flax-Merchant, Londonderry. No Cards.

DEATH.

ONUSTON.—On April 21st, at Bandon, H. B. Onuston, M.D., Medical Officer of Bandon Dispensary District, Bandon Union.

Advertisements.

GOLD MEDAL AND AWARD OF £664

OBTAINED BY MONSIEUR LAROCHE.

HIS QUININE LAROCHE (Bark), Excellent Tonic, Restorative and Febrifuge, contains all the principles of the red, yellow, and gray Quinquinas.—Paris, Dépôt, 15, Rue Druout.

London: Mr. Yozeau, 49, Haymarket; Mr. Wilcox, Oxford-street.

To be had also of all the principal Country Chemists.

DR. CHAPMAN'S SPINE BAGS (PATENT) for the Treatment of Disease by the application of Cold and Heat along the Spine, are sold by C. Macintosh and Co., 3, Cannon-street West; S. Maw and Son, 11, Aldersgate-street; J. G. Gould, 198, Oxford-street, London; also by Thomas Chapman, 56, Buchanan-street, Glasgow; and may be had by order of all Druggists. A description of the different kinds and sizes of the Bags may be had on application to any of the Agents named above.

BOOKBINDING.

M. & J. SULLIVAN are provided with the greatest facilities for executing BOOKBINDING in every style, and in the best manner, *expeditiously*, and with *punctuality*. Their prices will be found the *lowest* in the trade.

*** Special terms for the binding of Libraries, or for lots of 50 vols. and upwards.

M. & J. SULLIVAN,

Educational Publishers, Bookbinders, &c., 27, Marlborough-street, DUBLIN.

RUPTURES.—MORPIE, Patent Truss Maker. 18, Hawkins-street, Dublin. ESTABLISHED 100 YEARS.

Suspensory Bandages, Belts, &c., &c.

REDUCTION IN THE PRICE OF

LIQ: FERRI PHOSPH: MAGNET: CONC:

Magnetic Solution of Phosphate of Iron.

(LIGHTFOOT.)

This preparation is exceedingly stable in its composition. It has given satisfaction to all the Medical Gentlemen who have prescribed it, and has been found especially beneficial in the various forms of HEART DISEASE and ALBUMINURIA. Being dissolved in a solution of Citric Acid, its value as a TONIC is greatly enhanced. It is very agreeable to take, and forms, with Syrupus Aurantii, an elegant mixture.

Wholesale Agents for the North—

CLARKE, BLEASDALE, BELL & TOLLINGTON, YORK.
T. STANDRING & SON, MANCHESTER.

For London and the South—

SAVORY & MOORE, NEW BOND-STREET.

Reduced Prices—20 oz., 6s. 6d.; 10 oz., 3s. 4d.

EFFERVESCING

COMPOUND CITRATE OF POTASH WATER.

IN a Series of Lectures on Gout, Rheumatism, Rheumatic Gout, and Sciatica published in the *Lancet* by Dr. FULLER, attention was drawn to the extraordinary virtue of **Citrate of Potash** in neutralising the acid products of indigestion and in ridding the blood of the uric acid and other acid materials. In confirmation of this opinion Dr. ROBERTS of Manchester, in an admirable paper published in VOL. XLVIII of the "Transactions of the Royal Medico-Chirurgical Society of London," proves, by a series of elaborate experiments, that the solvent power of **Citrate of Potash** in **gouty urinary deposits** exceed that of Lithia and all other alkalies, and when combined with certain materials calculated to correct **acidity**, proves the most **valuable of antacid and gouty remedies**, neutralising the acid which exists in the blood, and preventing its being passed through the kidneys in the form of **gravel**. It is very agreeable and refreshing. Two or three bottles may be taken daily.

PREPARED ONLY BY W. TWINBERROW AND SON,
2, EDWARD-STREET, PORTMAN-SQUARE; AND 45, WESTBOURNE GROVE, LONDON, W.

TO THE MEDICAL PROFESSION.

AS on very many occasions our Medical friends have sent samples of Urine for Analysis, and, owing to our press of business we were unable to undertake them, in order, therefore, to accommodate the Medical Profession generally, we have entered into arrangements with Dr. Austin, who has for many years devoted his attention to that department of Medical Science, and whose Analysis we are sure will be found satisfactory.

GEORGE OLDHAM AND CO.,
Apothecaries, &c., &c., 107, Grafton-street.

DINNEFORD'S FLUID MAGNESIA

Perfect in purity and strength.

"The Fluid Magnesia I obtained from you corresponds precisely with that of the 'British Pharmacopœia,' 1867, and is what the preparation should be."—Professor Redwood.

Sold in Gallon and Half-Gallon Jars for the use of the Profession, by all Wholesale Druggists, and by the Manufacturers,

DINNEFORD & CO., PHARMACEUTICAL CHEMISTS,
172, New Bond-street, London.

MUSTARD POULTICES ENTIRELY SUPERSEDED
BY THE USE OF

(REGISTERED.)

Cooper's Sinapine TISSUE, or MUSTARD PAPER, recommended by the Faculty for the instantaneous production of Mustard Poultice, possessing the following advantages:—It will neither blister nor mark the most delicate Skin, and can therefore be most conveniently applied to the face, neck, or other exposed part: its effect is immediate and uniform. As it is unaffected by change of climate, and extremely portable, it must become a household remedy of great value in every part of the globe. Suitable equally for infants as adults. In Packets, at 6d., 1s., and 2s. 6d., and in large packets for the Medical Profession, at 3s. 6d. and 6s. 6d., equal to six and twelve 1s. packets, with medical testimonials and directions for use. Free by post on receipt of stamps, from the Inventor, A. COOPER, Pharmaceutical and Dispensing Chemist, 18, Abingdon terrace, Newland-street, Kensington, London.

JAMES'S FEVER POWDER, 4s. 6d. per bottle,
Packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

THE SCIENTIFIC WONDER.

THIS INSTRUMENT has a clear magnifying power of 32,000 times, shows all kinds of animalculæ in water, circulation of the blood, &c., &c., adulteration of food, milk, &c., and is just the Microscope that every Surgeon, Dentist, Schoolmaster, Student, and Working Man should have.

It is pronounced by the press (and all scientific men who have seen it) to be the best, cheapest, and most simple microscope ever invented.

It has twenty times the power of the Coddington or Stanhope Microscope, and is twice as good as the celebrated Rae Microscope (which has been awarded so many prize medals), as may be inferred from the following letter received from Mr. Rae himself:—

"Carlisle, December 12th, 1867.

"To Mr. McCulloch, Philosophical Instrument Maker.

"Sir,—Having seen some of your Diamond-Plate Lenses, I write to ask your terms for supplying me with the same per 20 gross, as I consider them superior to mine.—Yours, &c.,

"RAE & Co., Opticians, Carlisle."

I beg to inform the public that I have no agents anywhere, and all pretended agents are impostors. The above Instrument can only be had from me, in Birmingham. Those at a distance who care for instruction and amusement can have it safe and free by sample post, with book of full instructions, on receipt of 32 postage stamps. Samples sent abroad two stamps extra.

All persons wishing further particulars and testimonials must send stamped and addressed envelope.

ADDRESS—

A. McCULLOCH,
Philosophical Instrument Maker,
No. 18, BLUCHER-ST., BIRMINGHAM.

Dr. LETHEBY'S

FOURTH LECTURE ON FOOD.

PRESERVATION OF FOOD.—UNWHOLESOME AND ADULTERATED FOOD.

It requires no argument to show that the preservation of food is a matter of great public importance; for it not only enables us to provide against actual want in periods of unusual scarcity, but it also affords the means of equalizing the distribution of food at all times, so that the excess of one country may be used in supplying the deficiency of another. In the pastoral districts, for example, of Canada, Australia, Tasmania, the Cape of Good Hope, Mexico, the Argentine Republic, and the Brazil, thousands of tons of meat are always available as food, and yet they are lost to us because of the difficulties of preserving the meat. In South America, at least two millions of beasts are annually slaughtered for the fat, skin, and bones, the flesh of which could be supplied here at less than 2½d. per pound. So also in Australia, the amount of meat available as food is practically inexhaustible. Last year Mr. Philpot stated to the Food Committee of the Society of Arts, that he himself was in the habit of melting down from 1000 to 1500 sheep daily for four months together; and that in the vast districts of rich pasture-land from Victoria to Brisbane, there was an unlimited supply of the very finest meat—all of which was at present entirely wasted, because of the difficulty of disposing of the flesh; and, therefore, the carcasses of the animals were melted down for fat. A bullock in Australia, he said, costs only from £3 to £4; and legs of mutton of the very best quality were, when salted, sold for three shillings a-dozen. If some simple and practicable means could be devised for preserving such meat, it might be supplied to our markets at less than 3d. a pound.

Until recently the only process employed for this purpose was the rude method of salting the meat, but the deterioration of it was so obvious, and the distaste for it so general, that it was only practiced to a limited extent, and for occasions when fresh meat could not be obtained. The salt junk of the navy in olden time was a good example of the wretchedly unwholesome and indigestible meat prepared, for it could hardly be called preserved, by this process. Recognising, therefore, the necessity for a better means of preserving food, the naval authorities of every country appealed to science, and gave the largest encouragement to inventors. A further stimulus to invention was created by the necessity for supplying our Arctic explorers with good and wholesome food during their long winter residence in the frozen seas of the north; and as that inquiry was set on foot, not merely for the purpose of discovering a north-west passage to our possessions in America, but also with the view of prosecuting scientific research in almost inaccessible regions, an unusual inducement was offered for the preparation of such food. The demand thus created was soon acknowledged by science, and was also met by the practical skill of the manufacturer, so that the Arctic voyager went confidently on his journey, knowing that he had other food than the unwholesome junk of the navy. The earliest preparations supplied to him were mixtures of dried meat with sugar and spice (*pemmican*), but after a time they were furnished with fresh meat, preserved in air-tight cases. At first the supply was chiefly for voyagers in cold countries, but when the value of this method of preservation became known, the European residents of hot climates, as India, eagerly sought for the fresh foods which they were accustomed to use in their own country, and thus an additional stimulus was given to this process of manufacture. At the present time it has acquired gigantic proportions.

I have before me a list of the specifications of patents relating to the preservation of food, from the year 1691 to the end of 1855, and I find that one only was described in the seventeenth century, and 3 in the eighteenth, while as many as 117 were specified in the first 55 years of the present century. Invention, however, has not been prolific of new processes, for it is mainly confined to an application of one or two simple elementary principles—26 of the patents, for example, are for the preservation of food by drying; 31 by excluding atmospheric air; 8 by covering the food with an imperious substance, as fat, extract of meat, gelatine, collodion, &c., and 7 by injecting meat with various salts.

But before we proceed with the examination of these processes, it will be advantageous to inquire a little into the circumstances which favour organic decomposition. It would seem from experiment and observation that three concurrent conditions are absolutely necessary for active

putrefaction—namely, the presence of much moisture, the access of atmospheric air, and a certain temperature, as from about 40° to 200° of Fahrenheit; any of these being absent, the organic substance resists decay. All preservative processes must, therefore, depend on an application of one or other of these principles; and perhaps we may add a fourth—namely, the action of chemical agents. Let us review these in detail.

1st. *The preservation of substances by drying them* is of very ancient date. In our anatomical museums we have long known that specimens of the animal body may be preserved for an indefinite time by drying them, and then varnishing them so as to exclude moisture. Here is a dissection prepared in that manner, which has been used for lecture illustration at the London Hospital for more than half a century, and yet it is as sound as when it was made. In warm climates it has been a practice for ages to preserve fish, and even meat, by drying them—the meat being cut into strips and exposed to the action of warm dry air. Charqui or South American beef, which you see here, is an example of it. It is obtained from animals that are grass-fed, and they are killed by pithing and then bleeding them. Directly the hide is taken off, the flesh is stripped from the bones and allowed to cool. It is then placed upon a table, and jerked, or cut up into thin slices, which are piled up in heaps with alternate layers of salt. After standing twelve hours the meat is turned, and fresh salt is added where necessary. The next day the salted strips are placed upon hurdles, and exposed to the sun to dry. It requires two or three days to dry the meat thoroughly, and, for fear of damp, it is always taken indoors at night. There are several varieties of this meat, as *pato*, which is the best and most free from sinew; *manta*, the second quality; and *tasajo*, the third, which is very thin and full of sinews. All the varieties require to be well soaked in water, and then to be cut small and cooked by prolonged boiling. But animal foods are not well preserved in this manner, as they lose their flavour, and become tough and indigestible: the fat also gets rancid; and in damp weather the meat absorbs moisture and becomes mouldy and sour. Perhaps the lean parts of meat, as the heart, the tongue, and strips of muscle might be advantageously preserved in this way, especially in warm and dry climates. The food committee of this society reported favourably of a specimen of dry powdered beef from Queenstown, which they said was in excellent condition, and contained about four times as much nutritious matter as ordinary meat. Generally, however, the fat is very rancid, even when pains are taken to prevent the substance from getting mouldy. It is on this account that all attempts to preserve milk and the yolk of eggs by drying have failed, although the dried white of egg will keep well, as in the process of Mr. Charles Lamont, where the albumen is dried in thin scales—forty-four eggs making about one pound of the preparation. Absorbent substances mixed with the fatty food will obviate the difficulty to some extent, as in the preparation of *pemmican*, where sugar and spice are added to the dry powdered meat: and in the several processes for preserving milk by evaporating it and mixing it with sugar, &c., as in the patents of Newton (1835), Grimwade (1847 and 1855), Louis (1848), &c.; as well as the process of Davison and Lymington (1847) for preserving eggs by mixing the yolks and whites with flour, ground rice, or other farinaceous substance, and drying. Extract of meat also may be preserved in the same manner, as in the patent of Donaldson (1793), of Robertson (1851), and of Borden (1851), where the extract, after the separation of fat, is mixed with farinaceous matters; in the last case is also baked in the form of biscuits. In the year 1854 MM. Blumenthal and Chollet obtained their patent for combining meat and vegetables in the form of tablets, by first drying the meat and vegetables and pressing into cakes, and then submitting them to successive immersions in rich soup—allowing them to dry in warm air after each immersion. When the extract of meat is made without fat or gelatine, as in the case of Liebig's extract, it may be kept for a long time in a pasty condition, without mixing it with farinaceous matters, although the preparation of it with baked flour, as already described, is a great improvement.

The process of drying is, however, best adapted for the preservation of vegetable substances, and it has been so used from time immemorial, as in the keeping of pot-herbs, in preparing the tea-leaf, in making hay, &c. In this country the first recorded patent for preserving vegetables by drying them was granted in 1780 to John Graefer, who sought to retain the flavours of vegetables by first dipping them in boiling salt and water, and then drying. Forty years later (1820) John Vallance obtained a patent for preserving hops by drying them, and compressing them into a small space. Then came the patents of Edwards (August, 1840) for boiling, granulating, and drying potatoes; and of Grillet (November, 1840) for preserving both cooked and uncooked potatoes by drying. Ten years afterwards (in November, 1850) Masson obtained his patent for preserving vegetables by drying them and forcibly compressing them, so that they were reduced to one-seventh their original bulk—a cubic yard containing rations for 16,000 men. This process has been very successful, and it is still practised by Devaux, Chollet, and others, for it serves for the preservation of all kinds of vegetables, as potatoes, cabbages, carrots, cauliflowers, beans, apples, &c.; and when steeped in water they re-absorb their natural proportions of moisture and swell out to their original size. They are, however, somewhat deficient of flavour, and they require prolonged boiling, as from one and a-half to one and three-quarter hours to cook them.

By a more careful process of drying, Mr. Makepiece has managed to preserve both the colour and the flavour of vegetables, especially of pot-herbs, as you may see from these specimens.

Altogether there are, or have been, about thirty-one patents in this country for the preservation of various articles of food by drying them.

2nd. *The preservation of organic matter by excluding atmospheric air* is, like the last, a very ancient process. The old practice of burying the dead in leaden coffins, and the still more ancient custom of swathing them in resinous bandages or waxed cloths (called cerements), owe their preservative power to the exclusion of atmospheric air; and it is remarkable, seeing the efficacy of the process, that the scientific principle of it was not long ago recognised and applied to the preservation of food. The first patent of the kind that I am acquainted with in this country, was granted to Francis Plowden, in June, 1807, and he describes it as a process for "preserving butcher's meat, animal and other comestable substances, by encrusting them with a substance, which must not only resist the effects of atmospheric air, but must not communicate any noxious quality to its contents," and for this purpose he employed essence or extract of meat—the substance being dressed, so that it may preserve the longer, is wiped dry, and put into a wooden vessel, and the hot extract is poured over it in a fusible state, so as to find its way into every vacuum. Three years later (in February, 1810), Augustus de Heine took out the first patent for preserving meat, by exhausting the air from the vessel containing the meat, and he contrived a machine for the purpose, as the action of the common air-pump was tedious. Six-and-thirty years after this (in 1846), the late Mr. Warrington of Apothecaries' Hall, obtained his patent for the preservation of animal substances, by coating them with common glue, gelatine, or concentrated meat gravies, or otherwise by dipping them in warm solutions of such substances; or by wrapping them in waterproof cloth, or covering them with caoutchoue, gutta-percha, or varnish. These mark the starting-points of the various processes now in use; for example:—

(*a*). Of those which owe their operation to the exclusion of air, *by filling up the vessel with something hot*, there are the patents of Plowden (1807), who used rich gravy or extract of meat; of Granholm (1817), who used hot fat, or hot animal jelly; and of Wothly (1855), who used oil, as

in preserving anchovies. I am rather surprised, considering how easily the exclusion of air is effected by surrounding the substance with hot fat, that this method of preserving meat has not been adopted in Australia and South America; for as the fat which they prepare from their wild stock is sent to this country in casks, there would be no difficulty in sending with it the finer descriptions of joints, as legs of mutton, and good pieces of beef. The process should be conducted as follows:—When the fat is melted, and is at a temperature of from 240° to 250° Farh., the fresh joints should be plunged into it, and kept there for a few minutes, so that the superficial moisture might be thoroughly evaporated. They should then be immediately packed in sound dry casks, and filled up with hot fat, at a temperature of 212° or thereabout. In this manner the fat and the joints might be transmitted to this country, and on their arrival there would be no difficulty in melting the fat while in the casks, and then removing the preserved joints.

Vegetable substances are frequently preserved in bottles filled up with hot syrup, and the practice is a very old one. Hot water is also used for the same purpose, and this method dates from the year 1807, when this Society gave a premium to Mr. Saddington for his method of preserving fruits without sugar. His process was to gather the fruit a little before ripening, and to put it immediately into clean bottles—filling the bottles with the fruit to the neck. They were then placed in a vessel of cold water, and heat was applied until it rose to the temperature of 160° to 170° Farh. After standing exposed to this temperature for half-an-hour, the bottles were filled up to within an inch of the top with boiling water, and were then immediately corked and covered at the top with cement. The action of the heat was not merely to expel atmospheric air from the bottles, but also to coagulate the vegetable albumen of the fruit. Fruits and green vegetables are still preserved in this manner, a little alum being generally added to the water in the bottle, for the purpose of hardening the tender skin of the fruit, and so preventing its disfigurement by bursting.

(b). A process not very unlike the preceding is that which consists in *the destruction of the oxygen of the air in the vessel, by heating the substance in it.* This is the plan of M. Appert, who in 1810 (three years after the publication of Mr. Saddington's method), obtained the reward of 12,000 francs, offered in the preceding year by the French Government, for the best method of preserving food. Here is the book which M. Appert wrote at the time, and he tells us to cook the food to some extent, and put it into strong glass bottles—filling them almost to the top. The bottles are then to be securely corked, and exposed for some time to the action of boiling water. To guard against accident from bursting, the corks are to be wired down, and the bottles wrapped up separately in cloths. After this the corks are to be well covered with pitch, to exclude atmospheric air. A like process was patented in the autumn of the same year (1810), by Mr. Peter Durand, who, no doubt, derived it from the published account of M. Appert, dated nine months before, and since then many such patents have been obtained, which I need not describe. Attempts have frequently been made to preserve milk by this process. Appert recommended that the milk should be boiled down to about half its bulk before putting it into the bottles, and in 1847 Bekaert tried to improve the process by adding carbonate of soda to the milk. Later still, in the same year, Martin de Lignac obtained a patent for preserving milk, by evaporating it to one-sixth of its bulk before bottling it. Then there were the patents of Symington and of Morean (1853), but all these methods have failed in practice, on account of the difficulty of preventing the separation of the butter.

(c). The preservation of food *by exhausting the air from the vessel containing it* dates, as I have said, from the year 1810, when Augustus de Heine proposed to use a vessel with a valve in the top of it, which allowed the air to be drawn out by means of a special apparatus, but not again to enter. The exhaustion, however, was so imperfect that the process did not answer. In 1828 Mr. Donald Currie improved it by admitting carbonic acid gas into the vessel after it was thoroughly exhausted; and later still, in 1836, M. Leignette still further improved it, by filling the vessels containing the food, with salt and water, and then letting out the liquid through the aperture, which remained open for that purpose, while carbonic acid gas went in. Six years after this (in 1842), Mr. John Bevan patented a process for drawing out the air by an exhausting apparatus, and then admitting a warm solution of gelatine; and in 1846 Mr. Rettie employed, in the like manner, a solution of common salt. But none of these methods were successful; nor was the patent of Mr. Ryan, in 1846, for using gases, chiefly acetic acid vapour, and carbonic acid gas. The most perfect process of this kind was patented by Messrs. Jones and Trevethick. It consists of an apparatus whereby the exhaustion of the vessel containing the raw food is effected in an air-tight trough of water, and thus the entrance of air and the collapse of the sides of the vessel are completely prevented. After the exhaustion pure nitrogen is admitted into the vessel for the purpose of diluting the residuum of air, and it is again exhausted. Lastly, a charge of nitrogen containing a little sulphurous acid is let into it, and thus the last trace of oxygen is chemically absorbed. The vessels are now in a proper condition for removal from the air-tight water trough, and for having the apertures sealed with solder. Meat, fish, and poultry preserved in this manner has been found good after seven or eight years; and specimens of them were exhibited in the London exhibition of 1862.

(d). The most common method of driving out the air *is by means of steam.* The food is put with a charge of water into a tin case with a hole in the top, and when the water is boiling actively, and steam has displaced the air, and is escaping freely, the hole is stopped with solder. This process dates as far back as 1820; but the first patent for it was granted to M. Pierre Antonie Angilbert in 1833. He had, however, a very rude method of applying heat to the tin vessels, and this was improved by Wertheimer in 1840. In the month of January of the year following Mr. Gunter improved it still further; and later in the same year both Goldner and Wertheimer obtained patents for using a bath of muriate of lime for heating the vessels. This in fact is the practice at the present time by Goldner, McCall, Richie, Morton, and others, who are largely engaged in the preservation of food. The details of the process for effecting it are as follows:—The raw meat and vegetables are put into the canisters and soldered down—a pin-hole aperture being left in the lid. The canister is then subjected to the heat of the bath (a little above 212°) until the contents are about two-thirds cooked; and then, while the steam is blowing freely out, the aperture is dexterously sealed tight with solder. The canister is then painted over with a stiff oil paint, and is exposed for some time in the testing-room to a temperature sufficiently high to promote decomposition. If the canister shows no sign of bulging out from the generation of putrefactive gases, it is considered sound. Messrs. Hogarth and Co., of Aberdeen, use steam instead of the muriate of lime bath.

Meat preserved in this manner will keep for a considerable time. At the exhibition of 1851 vouchers were given for some of the samples that had been preserved for twenty-five years; and at the exhibition of 1862, I tested specimens of food which had been kept for more than thirty years. To night, through the kindness of Messrs. Crosse and Blackwell, I am able to show you a specimen of preserved mutton, which has been in the case forty-four years, and you will perceive that it is in excellent condition. It formed part of the stores supplied by Messrs. Donkin and Gamble in 1824 to his Majesty's exploring ship *Fury*, which was wrecked in Prince Regent's Inlet in 1825, when the cases were landed with the other stores, and left upon the beach. Eight years afterwards

(in August, 1833) they were found by Sir John Ross in the same condition as they were left; and he wrote to Mr. Gamble at the end of that year saying, "That the provisions were still in a perfect state of preservation, although annually exposed to a temperature of 92° below and 80° above zero." Some of the cases were left untouched by Sir John Ross; and after a further interval of sixteen years the place was visited by a party from H. M. ship *Investigator*, when, according to a letter from the Captain, Sir James Ross, "the provisions were still in excellent condition, after having laid upon the beach exposed to the action of the sun and all kinds of weather for a period of nearly a quarter of a century." Messrs. Crosse and Blackwell have placed the original letters in my hands for perusal, and they show beyond all doubt that meat preserved in this manner will keep good for nearly half a century—in fact the case of boiled mutton, now before you, has been preserved for forty-four years. There can be no question, therefore, as to the success of the process; and hence it is largely practised, not only in this country but also in our colonies where food is abundant. In this way preserved salmon and lobsters are sent to us from Newfoundland, turtle from Jamaica, beef and mutton from Canada, and the dainty tail of the Kangaroo from Australia. There are, however, two serious objections to the process—namely, that the meat is nearly always overcooked, and the cases are liable to buckle and crack from the constant pressure of the atmosphere—there being a vacuum within them. The over-cooking arises from a desire to ensure the complete exclusion of atmospheric air by the steam. Mr. Nasmyth has proposed, in his patent of 1855, that a little alcohol should be mixed with the water, so that the boiling point may be reduced; while Mr. M'Call, taking advantage of the absorbent action of sulphite of soda on oxygen, recommends a less prolonged boiling, and the use of a little of that salt. The salt is contained in a small capsule, fixed by means of soft solder to the inner surface of the cover of the case. When the food is about two-thirds cooked, and steam is freely escaping, the hole in the lid is stopped with a very hot iron, which melts the soft solder of the capsule within, and so sets free the little pellet of sulphite of soda, which speedily absorbs the remnant of oxygen left in the case.

The other difficulty, namely, the cracking of the case from atmospheric pressure, is obviated, as I have already explained, by the introduction of inert gases, as carbonic acid, nitrogen, &c., with a little sulphurous acid, and these have been the subject of many patents, as of Currie (1828), Leighette (1836), Ryan (1846), Nasmyth (1855), and others.

(e). The last method of any importance for excluding atmospheric air from food, is *by coating it with some impervious material.* This plan, as I have already stated, was first suggested by the late Mr. Robert Warrington, who, in March 1846, obtained a patent for the use of "common glue, gelatine, or concentrated meat-gravies; or hin cream of plaster of Paris, which, when set hard was to be saturated with melted suet, wax, stearine, &c." "The things were then to be wrapped in water-proof cloth, or covered with caoutchoue, or guttapercha; or coated with a varnish of these substances; or kept submerged in glycerine, treacle, elaines, oils, or other such matter not liable to oxydation." Nine years after this, in January, 1855, a patent was obtained by Messrs. Delabarre and Bonnet, for preserving meat, bread, eggs, vegetables, or pastry, by coating them with a varnish, made from the flesh and bones of animals, by boiling them, and obtaining a rich syrup. This when clarified was used to cover the parboiled meat, or vegetables. In the month of February of the same year, a like patent was granted to Mr. Hartnall, for a process of preserving animal and vegetable substances by immersing them in baths, consisting of gelatine and treacle dissolved together in certain proportions; then drying, redipping, and covering with charcoal powder. Later still, in the same year, Mr. Brooman patented the use of albumen and molasses, as a coating for meat, after the meat had been partially dried, and then suspended in an air-tight vessel, charged with sulphurous acid. Lastly, in the month of December of the same year, Messrs. Bouëtt and Douein obtained provisional protection for the use of collodion, either alone or mixed with other suitable substance.

But the best example of this method of preserving meat is the process of Dr. Redwood, whereby the meat is first covered with paraffin, and then with a flexible coating of gelatine, mixed with glycerin or treacle. The joints are dipped into a bath of paraffin, having a temperature of from 240° to 250° of Fahrenheit, and are kept therein until the surface moisture is evaporated. They are then transferred to a colder bath of paraffin, from which they receive two or three coatings, prior to their being covered with the last flexible covering of gelatine, &c. When the meat is required for use, the paraffin is easily removed from it, by plunging it into boiling water; which dissolves the flexible coating and melts the paraffin. The paraffin floats upon the water, and when cold may be collected for future use.

The common methods of preserving foods by forcing them into skins, as in the case of German sausages, lard, &c., is of very ancient date; although a patent was granted to Mr. Palmer, in 1846, for the preservation of the fat of beef, mutton, veal, or lamb, when fresh, by melting them, straining, and then packing in bladders.

(To be continued).

Original Communication.

THE RATIONAL TREATMENT OF CONSUMPTION.

By JOHN MULVANY, M.D., L.R.C.S.Ed., Etc.,
ASSISTANT-SURGEON, R.N.

(Continued from page 372.)

I HAVE presumed the existence of bronchial spasm, and will now proceed to state on what grounds this assumption is based. The decided and immediate relief which follows the act of Emesis—nature's own method of relieving spasm—first attracted my attention, and caused me to suspect its existence; but as the violent muscular efforts by which that act is performed would have the effect of emptying the vomica if no such or an opposite condition of those muscles obtained, I tried the effects of veratrum viride, the action of which in overcoming spasm without producing vomiting is well established. Free expectoration, and consequently diminished cough, were the immediate effects. But to ascertain more directly I tried to produce bronchial spasm by irritation of the pneumogastric. Having, with the assistance of a friend, cut down on this nerve in the neck of a dog, and loosely tied it with a thread, so as to keep up gentle but *prolonged* irritation, we found that after a short time the respiration became quickened, and that the act of inspiration was performed in a jerking, spasmodic manner, the whole body shaking with the inspiratory effort. From this I inferred that if an irritant was applied to a few peripheral twigs, as in a vomica, instead of to the entire trunk, the effects would be more local, and instead of the whole respiratory apparatus being spasmodically affected, those muscles only whose nervous supply was directly irritated would suffer—viz., the bronchial.

The following incident which lately occurred seems to point to the same conclusion. A medical friend of mine, whilst ruralizing during the hot weather, was stung by a bee behind the right frontal eminence. The pain which it occasioned at the moment was so slight that he took no notice of it; but a few hours afterwards the part stung became stiff and painful; slight lachrymation of the corresponding eye ensued; soon afterwards he experienced a sensation of numbness or stiffness passing from the ear to the side of the nose and angle of the mouth. Several hours afterwards a difficulty in swallowing ensued, and to

this succeeded a feeling of constriction of the chest, and an inability to take in a full inspiration. On examining the part he found the sting of the bee remaining, and on withdrawing this the symptoms yielded in a few hours.

In this case the sting of the bee acted somewhat similarly to the loose thread tied round the pneumogastric in the dog's neck, as shown in the preceding case. The explanation which he gave of the production of his symptoms is the following:—The sting irritated a branch of the temporo auricular nerve, which irritation, from its persistency, passed successively to the lachrymal, facial, pharyngeal, plexus, pneumogastric trunk, and through the pulmonary plexus, to the bronchial muscles, throwing them into a state of irregular action, a kind of sub-spastic condition, which mechanically impeded the inflation of the lungs. If the sting produced a paralysing influence on the pneumogastric, there might be some difficulty in swallowing, as well as in respiration; but in the latter case it is the expiratory act that would be embarrassed. Again, if the action of the diaphragm were interfered with through the medium of the phrenic, there might be difficulty in inspiration. But the respiratory trouble being caused by the same influences which produced the difficulty in deglutition, we may presume that the œsophageal and bronchial muscles were in a condition similar to that of the *stiffened lygomatici*.

It may not be inappropriate to cite the following case as an instance of what I consider pneumogastric paresis, with slight relaxation of the bronchial muscles:—

A carpenter, J. W., æt. 29, was, in the month of January, 1867, exposed to a cold wind, which beat the falling snow against his right ear. Neuralgia of the face was the consequence. This after a few days disappeared. He then complained of cough and shooting pains through the right lung. The heart's action was quick and sharp, and the respiration was of a peculiarly nervous jerking character. The air entered freely into the chest, but its expulsion was attended with some difficulty, and accompanied by an exaggerated muscular fremitus. This case I considered one of neuralgia of the pneumogastric, with relaxation of the bronchial muscles, which, thrown into vibration instead of contraction during the expiratory act, produced the peculiar fremitus alluded to, and prolonged the expiration. The sharp, quick action of the heart, analogous to that produced by section of the vagus, showed that the inhibitory action of that nerve was in abeyance. A few six-grain doses of potassii iodidi removed the symptoms in twenty-four hours.

That the sympathetic is in a state of excitement from the continued irritation conveyed to it from the vomica, I inferred from the accelerated action of the heart, the quick small pulse, and dry skin. The sympathetic presides over and governs the functions of the circulatory system. The pneumogastric, however, seems to be concerned in the governance of the heart's action, its action being the opposite of the sympathetic, section of the one producing the same effect as stimulation of the other. Acceleration of the heart being produced in either case, it may, therefore, seem somewhat contradictory to assert that the quickened action of the heart is due to excitation of the sympathetic, at the same time that the vagus is also irritated, since the acceleration by the former would be neutralised by the slowing by the latter. But it is easy to understand that the pulmonary branches of the pneumogastric may be excited without its cardiac filaments partaking in the excitation, just as certain portions of the sympathetic are excited by belladonna or ergot, and depressed by veratrum viride, which, whilst it restrains the activity of the thoracic and abdominal ganglia, appears to exert little or no influence on the cervical.

Again, my idea that the sympathetic is morbidly excited by the vomical irritation, receives confirmation from the following facts. Belladonna in poisonous doses will give rise to the same heat of skin, dryness of the body, and acceleration of the heart. Similar effects will be occasioned by prolonged irritation of the sympathetic in the neck. Moreover, the cold stage of ague, characterized by a quick, small pulse, increased heat of body as shown by the thermometer, and relative coldness, with pallor of the surface, due to extreme contraction of the coats of the small arteries producing a stoppage of circulation through them, is caused by extreme activity of the sympathetic. When this extreme activity becomes abated, as in the hot stage, we have a condition of the system produced similar to that observed in phthisis: when a vomica has existed for some time, the excited sympathetic stimulates the heart to increased action, but the stimulation being less than in the first stage, the small arteries permit the passage of blood through them, and the skin becomes hot, but its organic muscular fibres remaining still contracted, and the coats of the small arteries being in a similar condition, and therefore, as it were, condensed, prevents the blood (circulating through them) from yielding up those portions of its constituents which should be eliminated by the sudoriparous glands. Hence, the body remains dry; the heat, which should have been carried off in evaporation, being retained, tends to produce that elevation of temperature so characteristic.

Thus, as in the first instance, the depuratory action of the skin becomes thrown out of gear, but in a different manner, and the elements retained in consequence in the blood, along with the effects of sub-oxidation, which as I have shown still exists, will, when sufficiently accumulated to produce a still further stimulation of the sympathetic, give rise to rigors. It is possible that the motor nerves may be irritated and that this irritation may have something to do with the production of the rigors, but to me it seems more probable that the sudden shutting off of the blood from the arteries of the skin, and the consequent deprivation of heat from the surface of the body, produces them, just as cold will make the frame shiver and the teeth chatter. Hence, probably, their short duration. But as over-exertion is followed by fatigue, so is hyperstimulation by depression, arterial relaxation and profuse sweating naturally result—nature, by this means, purging the system of the unhealthy products which produced the perturbation. To this relaxation, sleep, darkness, and the recumbent position, materially contribute, and therefore the patient's perspirations are nightly, and most profuse when the pulse is lowest, viz., towards morning. And now I may ask, is it logical to try to check those perspirations? Does it not look like closing a safety valve which nature herself has opened? By administering acids or astringents, as is usually done for night sweats, we are, to use a metaphorical expression, driving nails into the patient's coffin, because we thereby aid the vicious activity of the morbid action going on in the vomica. As the depressed state of the sympathetic passes off, it again becomes irritated by the morbid cell-action in the vomica. The pulse begins to rise again, the symptoms undergoing a gradual exacerbation, until finally the same cycle of symptoms are reproduced, the evening exacerbations, chills, flushes, and night sweats.

But besides the influences brought into action from within by the great tubercular factory, there are others which operate on the patient from without in a manner equally decided and more manifest. I allude to atmospheric influences. Having kept a meteorological journal since my entering into the service I have often observed the influences, frequently inexplicable, which atmospheric vicissitudes exert in the production or modification of disease, but in no other disease have I seen their effects so strikingly illustrated as in phthisis. Its electrical condition, the absence or presence of ozone, and its quantity, the state of the barometer and thermometer, seem to be the conditions most intimately associated with the varying conditions of the phthisical patient. Thus on a fine clear day, when the ozonometer shows a tolerable amount of ozone, when the atmosphere is electrified, positively the phthisical patient finds himself in capital spirits, with all his symptoms ameliorated. But when the sun is overcast, and but dimly seen through a stratum of greyish clouds, or a few darker and thicker ones float lazily nearer to the earth, with a moisture in the atmosphere, a diminution or com-

plete absence of ozone and negative electricity, all his symptoms are aggravated. A high thermometer, as in the month of July, is unfavourable, a falling or low barometer is, on the contrary, favourable, provided it is not accompanied by moist winds. Thus in the month of January, 1867, which I should say is the healthiest month of the year in Canada, the mean height of the thermometer taken every four hours was 19° Fahr., the range from 14° below zero to freezing point. The mean height of the barometer for the same month taken at the same hours was 29°·33, the range between 28°·80, and 29°·92, thus, contrary to what might be expected, the barometer during the coldest was on the average lower than any other month in the year. The climate of Canada has been much extolled for its adaptability for consumptive cases, but I think it has been overrated. With the exception of a part of December, the whole of January, a portion of February and of March, in which the air is cold and bracing, the thermometer and barometer low, the sky clear blue, and the ground covered with snow, I should say the climate is but little suitable for such patients; the spring weather is too changeable, the atmospheric vicissitudes too sudden, the winds too keen and biting, and the showers of rain too frequent. The summer is better, the weather is more uniform, the sky is clear, the atmosphere positively electrified in a tolerable state of ozonization, with little rain or wind. In July, August, and September, the heat is rather too strong—however, the fall of the year is characterised by the same vicissitudes as the spring, excepting that small (frequently I believe) mythical portion called the Indian summer; the weather is then mild, neither possessing the hotness of the summer nor the coldness of the winter, foggy in the morning, and smoky in the evenings. This smokiness is its peculiar characteristic. *Meteorology* is a science, the study of which is highly interesting and instructive; not only will its investigation enable us to establish the dependance of some diseased states of the human system on certain atmospheric conditions and thus become a guide to their treatment, but will also throw light on many of the occurrences of daily life, usually put down as "curious coincidences." The affinity which exists between certain states of the barometer and thermometer, the degree of humidity or dryness of the air, and the preservation of health or prevalence of disease, is truly remarkable. Still more remarkable are the atmospheric influences produced through the media of its ozonic and electrical conditions, differing as the ozone is in excess or deficiency, as the electricity is positive or negative, in a state of tension or otherwise. The vivifying tonic properties of positive electricity have long ago been hinted at by Wilson Philip, and established by later experimenters. That negative electricity produces opposite effects on the human system is tolerably certain.

The production of an intractable ulcer on the leg by the application of a zinc plate to the skin, and a copper plate over that, and the rapid healing which takes place on reversing the plates, as reported by, I think, Dr. Colles, gives an admirable illustration of the effects of the opposite electricities. I have long had an idea that the science of astronomy might be made subservient to the healing art. For if we could connect certain atmospheric conditions with the production of diseases and accidents, as I think we can, we might, by watching the evolutions and conjunctions, &c., of the heavenly bodies, predict the coming weather, and take precautions against the accidents which are likely to be occasioned thereby. Let me illustrate my meaning. Medical jurists tell us that at times men are subject to uncontrollable impulses to commit crime, and Captain Grounow, in his memoirs, mentions the case of a Frenchman, who was seized with *une envie de tuer quelqu'un*, whilst at table rushed out of the room, killed a man, and returned. A look at the newspapers from time to time, will show that suicides and babies usually occur in batches. The same may be said of toothaches, delirium tremens, cases of fractures, and other accidents; cases of drunkenness follow a similar rule, illustrating the adage of Kitty of Coleraine—"That misfortune seldom comes single or plain." Now the question arises, can we in any way connect the state of the weather with the breaking of one man's rib, the fractured leg of another, the black-eye received by a third, the severed jugular of a fourth, or the *envie de tuer quelqu'un* of a fifth. I think we can. In the Gulf of Mexico, the officers and men of the ships stationed there get into a frame of mind, known throughout the service as gulfiness, characterised by a cantankerous captious feeling, a readiness to take offence and quarrel with anybody. This condition of gulfiness is evidently owing to the high electric tension of the atmosphere peculiar to Central and South America, the men and officers seldom being able to go ashore, and work off their superabundant electricity.

The opposite condition may be observed in our own more triste climate, where the atmosphere is very often negatively electrified. There the negative electricity produces a depressing effect on the mind, the potency of which may be inferred from the ulcer producing capabilities of negative electricity, by the zinc and copper pile, already alluded to. This depressed frame of mind, familiar to all of the nervous and sanguineous dispositions, and experienced on the *dias pesados*, is precisely opposite to the condition which exists in gulfiness, the *envie* it produces is towards self-destruction. The restlessness of the natives of Central and South America, and the continual wars, revolutions, and quarrels, which go on there, are, no doubt, in some manner attributable to the high state of electric tension of the atmosphere in those parts. Transplant the fighting Columbian to England, and the suicidally inclined Englishman to Bagota, and ten to one but Chilolo will cut his throat, and John Brown will head a rebellion. Again, on the 2nd ult., a well behaved seaman, of good character, went ashore, broke the pledge and his tenth rib; three days afterwards, another equally well-disposed man went ashore, and severely contused the eight, ninth, and tenth ribs; on the following day, another man went ashore, and got his tenth rib, same side, broken. By what mysterious coincidences, I may ask, were these three men impelled to go ashore, abjure teetotalism, and as a natural consequence, become inebriated, stumble, and sustain the accidents above stated. The days on which these events occurred were essentially *dias pesados;* the negatively electrified atmosphere depressed their spirits, they probably experienced an *envie* to commit some rash act, or at all events the depressed frame of mind, of which that *envie* is the offspring, and they were driven to seek the cheering influences of old rye—a means, whereby they unconsciously restored the electric equilibrium in their bodies; but not content with that, they carried their potations too far, contused and broken ribs ensued, a commentary on their folly, and a memento of the influence of negative electricity.

(To be continued.)

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

EPISTAXIS—PLUGGING THE NOSE—ILLUSTRATED BY FOUR CASES.

Under the care of Mr. CROLY.

Case 1.—E. S., a female, aged 49 years, was admitted into the City of Dublin Hospital with bleeding from the right nostril, which had continued for several days. The ordinary remedies had been at first adopted by her medical attendant, who, as a last resource, plugged the anterior and posterior nostril. The hæmorrhage was thus checked for a short time, but having recurred, she was sent to the hospital. On her admission, it was found that the blood flowed down her throat, and also escaped anteriorly. The patient was much exhausted. Mr. Croly, finding that the plugs were not *then* effectual, considered it necessary to plug the nose again, and proceeded in the following man-

ner :—A piece of lint folded to the size of the last phalanx of the thumb was *stitched through its centre* with a hemp ligature, leaving *two* ends sufficiently long to pass through the anterior nostril, and *one* through the mouth. The plug thus made was moistened with muriated tincture of iron. The operator then took a gum-elastic bougie (No. 2) and transfixed its point with a needle armed with ligature-silk, and tied a loop on it; and (having removed the plugs which were first introduced) passed the bougie straight along the floor of the nostril; its point appearing behind the velum palati was seized in a long forceps, and drawn forwards through the mouth. The *double* ligature of the plug was passed through the loop, and tied. The bougie was withdrawn through the nostril, and the plug, held between the ends of the first two fingers, was guided behind the velum and wedged into the posterior nostril by the point of the index-finger of the left hand. During this stage of the operation the hæmorrhage was alarming, and blood was coughed out violently into the operator's face. The patient struggled, and tried to close her mouth. The two strings which were drawn through the anterior nostrils were untied, and held apart, and the nostril plugged from the front with pieces of lint introduced by a director, and secured by tying the double ligature tightly. The ends of these strings, and of that through the mouth, were fastened to the cheek with adhesive plaster. The hæmorrhage was thus fully controlled.

On the fourth day, pus having appeared at the nostril, a solution of chloride of zinc in cold water was injected into the nostril, and when the plug was sufficiently softtened, it was removed. By pulling the string through the mouth, the posterior plug was easily detached.

During her stay in hospital the patient was given light nutritious diet, and muriated tincture of iron was prescribed internally. Under this treatment she perfectly recovered, and was discharged from hospital in a few days.

Case 2.—M. M., aged 60 years, was admitted into the City of Dublin Hospital for excessive bleeding from the left nostril. The patient, who presented a pale anæmic appearance, stated that she was attacked a week previously with the bleeding. The usual remedies were first tried—and having failed, the anterior nostril was plugged with lint. This did not succeed in arresting the hæmorrhage.

Mr. Croly plugged the nose by means of Belloc's sound. Pus appeared at the orifice of the nostril ; on the fourth day the plug was removed, and the nostril syringed with "Condy's Fluid ;" the patient was discharged quite well in a few days.

Case 3.—A. B., a pensioner, 60 years of age, came under Mr. Croly's care for epistaxis, which continued for several days, and resisted all treatment. The patient was very much debilitated, the posterior nostril was plugged by means of Belloc's sound, and the hæmorrhage controlled.

Case 4.—Mrs. ——, aged 36 years, in the last month of pregnancy (one of the causes of epistaxis stated by writers), was seized with bleeding from the right nostril. The ordinary modes of treatment failed to arrest the hæmorrhage, which weakened the patient, and alarmed her very much. She was directed to snuff up a powder consisting of alum and sulphate of zinc. This having proved ineffectual, and the patient becoming very weak, Mr. Croly plugged the nose from the front by the late Surgeon Smyly's plan—viz., slips of lint a foot long and half-an-inch broad were introduced into the nostril by means of a gum-elastic catheter until the cavity was completely filled. The hæmorrhage was thus checked.

Mr. Croly made some practical remarks to the pupils on this important form of hæmorrhage, its various causes and modes of treatment, and pointed out the propriety of not interfering in certain cases in which the bleeding may be salutary, and impressed on them that plugging the nose should not be resorted to until the ordinary methods had proved unsuccessful.

These modes are raising the arm or arms above the head (as recommended and ingeniously explained by Dr. Negrier), cold applied to the forehead and nape of the neck, dry cupping the same region, placing the feet in hot water, directing the patient to snuff up astringent powders, &c.

He then detailed the several steps of the operation of plugging the nose, either by means of Belloc's sound, or an ordinary gum-elastic bougie or catheter, or by the method recommended by the late eminent Surgeon Smyly, of this city, which proved so successful in case 4.

Mr. Croly explained further the advantage of making the plug according to the plan described in case 1, which consists in stitching instead of tying it ; thereby avoiding the hour-glass shape which the plug assumes when tied, and allows the blood to escape into the throat in consequence of not filling accurately the posterior nostril. He also advised that the plugs should not be removed until signs of suppuration are manifested by pus appearing at the orifice of the nostril, lest hæmorrhage should recur.

Mr. Croly also reminded the class that plugging the nostril is not only a troublesome operation, but very distressing to the patient ; and is not unattended with dangerous results. Tetanus and pyæmia have sometimes followed, and the posterior plug in some cases has fallen down on the windpipe ; this dangerous occurrence is to be avoided by tying the double strings *tightly* on the anterior plug, and making the posterior plug sufficiently large. The string through the mouth will be found most useful in withdrawing the plug from the posterior nostril, and will not produce the irritation alluded to by writers, if properly secured by plaster on the cheek.

MATER MISERICORDIÆ HOSPITAL.

SYPHILITIC ENLARGEMENT OF THE LIVER AND SPLEEN.

Under the Care of Dr. HAYDEN.

HENRY C., aged 30, but in appearance much older, was admitted January 15, 1868—not intemperate, has served in the army over twelve years, and of that period passed 11 years and 8 months in India ; whilst there he had intermittent fever, and contracted syphilis of an aggravated character, which has left indelible marks upon him in various situations. In consequence of this his health became impaired, and he was discharged from the service. Four months previous to the date of admittance he vomited up a large quantity of dark clotted blood, and a few days subsequently a much less quantity.

State on admission—patient somewhat thin, but not emaciated ; face slightly bronzed, but not jaundiced ; pulse 100, and weak ; liver much enlarged, descending about three inches below the costal cartilages, prominent, and somewhat uneven on the surface, and tender to pressure ; hepatic dulness extended upwards to within an inch of the nipple, and the right costal cartilages were projected ; spleen enlarged, and firm to the touch ; several large and deep scars, the result of syphilitic ulceration, were visible upon his back and forehead, and likewise upon his legs and thighs, where they had assumed a deep brown colour ; there were also two minute perforations in the soft palate, doubtless of venereal origin ; both testicles enlarged, hard, smooth, and heavy, but free from tenderness; he reported that this enlargement commenced several months previously.

℞. Succi taraxaci, ʒiv.
Acid nitro-hydrochloric, ʒii.
Infusi gentian, co. ʒviii. ℳ.
St. coch. mag. ampl. ter indies.

He subsequently took, three times daily, a pill containing one grain of the green iodide of mercury.

On the 15th of January, iodide of potassium in infusion of cinchona (gr. vi. doses three times a-day) was substituted for the foregoing. On the 21st urgent diarrhœa set in, and continued several days, depite astringent medication of various kinds ; it ceased about the 27th, when the iodide of potassium was resumed, and was continued up to the period of his discharge.

The patient ned flesh, and lost in a great degree the

bronzed tint of face which he presented on admittance; he declared that he felt quite strong and well, and the liver underwent a marked diminution in volume; discharged, January 26th.

Dr. Hayden drew the attention of the class to the interesting features of this case, which he regarded as an example of syphilitic engagement of the liver and spleen. The diagnosis lay, primarily, between hepatic abscess and syphilitic enlargement, the former view being favoured by the long residence in India, the increase in volume, prominence, and tenderness of the liver; the latter, by the history and traces of secondary and tertiary syphilis, the occurrence of hæmatemesis and obstinate diarrhœa; and, finally, the absence of rigors, sickness of stomach, emaciation, and jaundice; the latter diagnosis was confidently made after the patient had been a few days in hospital, and iodide of potassium was prescribed accordingly. The beneficial effects of this treatment were strikingly illustrated in the reduction of volume in the liver, and the restoration of the patient to a state of comparatively good health within a brief period.

Proceedings of Societies.

MEDICAL SOCIETY OF LONDON.

April 20, 1868.

Dr. Richardson, F.R.S., President, in the Chair.

Mr. Davy exhibited a new needle adapted for various surgical purposes. It is so constructed that upon one handle many forms of needle may be fitted. It secures ease and accuracy in the introduction of sutures, and frequent threading is done away with.

Dr. Sansom quoted a case of co-existence of scarlatina and variola in a young lady, aged 26. Five days after a prefatory croyga the rash and throat signs of scarlatina appeared; at the same time occurred violent pain in the back and limbs. Seven days after the initial signs papules of modified variola commenced to appear, and developed in the ordinary way. There was on the ninth day from the commencement the phenomenon of a scarlatinal rash co-existence, with variola in the vesicular stage.

In the discussion which followed, Dr. Rugg, Dr. Leared, Dr. Llewellyn Williams, Dr. Woolfe, Dr. Farquharson, and the President took part. The first speaker alone had met with a similar case, but instances were related of the occurrence of scarlatina with measles, with a vesicular appearance somewhat simulating variola, with the signs of acute rheumatism, and of co-existence of variola and secondary syphilis.

Mr. Browning exhibited a new and improved magneto-electric machine. The magnet employed is circular, and the arrangement of the armature allows the passage of all the positive currents through one wire, and all the negative currents through the other. The instrument is elegant in appearance, very efficient, easy of management, and inexpensive.

The President testified to its value, and mentioned a case of aching of the stomach in which he had found it beneficial.

Dr. Leared had originally employed galvanism in these cases.

Dr. Oppert read a paper on the defects and recent improvements of existing hospitals. He advocated the warming of bath-rooms and water-closets. He suggested the establishment of a central institution for baths, especially medicated ones, for the out-patients of London hospitals and dispensaries; the physicians and surgeons to distribute tickets entitling to the advantages of the baths. He thought the washing in English hospitals greatly mismanaged, and advocated the adoption of the continental system. He eulogised the new Marylebone workhouse.

Mr. Peter Marshall read a paper on bichloride of methylene as a general anæsthetic. The discovery of the anæsthetic properties of this agent was attained by Dr. Richardson, by a process of induction; its qualities are intermediate between those of the gaseous and unstable chloride of methyl and the heavy liquid chloroform. The author described the physical and chemical characters of the new anæsthetic; like other bodies of its class, the boiling point is variable, its vapour is agreeable, and patients generally prefer it to chloroform. For its administration the author preferred a hollow cone of domet or other absorbent material, though Weiss and Dr. Junker's inhalers were valuable. Narcotism to the deepest degree could be induced with three drachms, in short operations one drachm or two drachms being necessary; complete anæsthesia can be induced in three minutes. A sign peculiar to its action is the occurrence of double strabismus.

For its administration a temperature of from 60° to 80° Fahrenheit is to be preferred. Patients submit to its agency quietly, and the delirium takes a "serious" turn. It has been said of patients, that "they groan under ether, swear under chloroform, and under bichloride of methylene they say their prayers;" the advantages of this anæsthetic may be thus summarised:—

Over ether.—More easy of administration, less sense of suffocation; no lividity.

Over amyline.—Less excitement; no collapse.

Over chloroform.—Quicker in action, less exciting, causing no headache nor depression, less chance of vomiting (author had met with vomiting in one in three cases of chloroform administration), anæsthesia more placid, more persistent; causing no rigidity of muscles of jaws.

After some remarks by Dr. Tilbury Fox and Mr. Hainworth,

Mr. Clover urged that as with other anæsthetics, so with this, a definite admixture with air was a desideratum; he had found a difficulty in obtaining the agent in a state of purity, he could not admit that stable substances could have variable boiling points. A specimen which had been sent to him presented the characters of a mixture of chloroform and ether. He approved of the effects of nitrous oxide, though the lividity which it induced gave a rather alarming appearance to the symptoms.

Dr. Sansom hailed the approach of the time when among many anæsthetics, a choice may be made for an individual case. It behoves us to be very cautious before giving up our old friend chloroform. He could not agree with the author's data on chloroform-vomiting. In his experience where chloroform was carefully and progressively administered, vomiting was very rare indeed. From the evidence given, he thought that the bichloride of methylene would be very valuable in dental operations, and those of lesser magnitude. With regard to nitrous oxide, he considered it a dangerous axphyxiant, and he expected, if its use were persisted in, to hear of a case, in which an enfeebled heart could not bear the distension of its right cavities, which the gas "proprio moter" induces.

After some observations by Mr. Davy and Dr. Camps,

The President expressed his satisfaction at the confirmation of his own views as to nitrous oxide; carbonic acid is just as unsafe, animals are very prone to die under its influence, and in America its danger has been proved by many deaths.

SURGICAL SOCIETY OF IRELAND.

27th March, 1868.

(Continued from page 388.)

Mr. Porter, Vice-President of the College, in the Chair.

TUMOUR OF THE NECK.

Mr. H. G. Croly exhibited a tumour he removed from the parotid region and the side of the neck of a woman 46 years of age, on Wednesday last, in the City of Dublin Hospital. The tumour was parotidean in its origin, extending beneath the jaw and behind the lobe of the ear. It had no very deep attachments, and was fourteen years growing. The patient was seen when the tumour was in an early stage of growth by the late Professor Porter, who recommended its removal at that time. The patient, however, would not consent. Three years ago she came under his (Mr. Croly's) care, and he then recommended its removal, but her timidity caused her to shrink from the operation. Hæmorrhage set in from the lower part of the tumour, which became somewhat softened, and it was then determined to remove it. Dr. Barker having made a microscopic examination, informed me that the upper part of the tumour was of a fibrous structure, and the tendency in the lower part of it was to degenerate into a malignant nature. There was not the slightest contamination in the glands, and from the great length of time the tumour had been growing, the return of it was not to be apprehended.

Mr. Richardson read a communication from Dr. Duggan, of Lackagh, on a

CASE OF NECROSIS OF THE TIBIA.

"Gentlemen,—I beg to place under your observation the

accompanying pathological specimen of necrosed tibia, which, I think, is rather rare, from the fact that nearly the whole shaft in its length and circumference was removed. The leading features and history of the case are these: I was called on the 28th of January last to visit a little boy aged nine years, who was suffering from necrosis of the tibia for the last two and a-half years. The poor little fellow was very much reduced, emaciated, and ill-fed. The general aspect of the leg was just what is ordinarily observed in this affection.

"Minute sequestræ, or an 'insensible exfoliation,' came away from time to time, through the burrowing and fistulous sinuses that pervaded through the soft parts. From the constant drain and irritation the child was very much weakened.

"About four inches above the ankle I observed a large orifice leading down directly to a corresponding cloca in the bone, which was about an inch apart from a similar one superior to the former. Having then passed a firm probe into each orifice, I detected by a to-and-fro motion that the dead bone lay floating beneath. Accordingly, I did not hesitate in operating, and at once cut down through the soft parts, and with a well-suited curved bone pliers, divided the isthmus between the clocæ, making a rather longitudinal orifice. A smart welling of venous hæmorrhage took place, which ceased a little by elevating the leg for a few minutes, by the aid of a rough-toothed duck-billed forceps. I very cautiously and with some difficulty removed this diseased shaft of the tibia. You will at once perceive that it is very nearly a complete necrosis of the whole shaft and circumference, the child being only nine years old.

"I have merely placed this under the notice of the society, because some days ago Mr. Mason laid before the London Medical Society the case of an adult from whose leg was thrown off about four inches of diseased tibia in its entire circumference, and which he considered a rare pathological specimen. My patient is doing very well ever since, and gradually regaining health and vigour.

"JOSEPH DUGGAN, Surgeon,
"Medical Officer Turloughmore Dispensary,
"County Galway."

The CHAIRMAN expressed the thanks of the Society to Dr. Duggan for his communication. He had often thought it a matter of regret that their professional brethren in the country did not more frequently send their communications, or come more frequently to their meetings, where they would always receive a hearty welcome. No doubt their avocations prevented them from coming often to town, but it was most desirable that any of them who met with cases of interest, should send the particulars of them to the Society.

Dr. BENSON—As one of the oldest Secretaries of the Society, I wish to express my concurrence in what has fallen from our Chairman. It is the most anxious wish of the Council of the Surgical Society to get papers from the country.

GUN-SHOT INJURY OF THE ORBIT.

By MR. WILLIAM STOKES.

There is nothing of wounds of the eye or orbit which are of greater interest and importance, and, therefore, better entitled to careful consideration on the part of the surgeon, than those resulting from gunshot injuries, and the particulars of the case which we shall presently discuss, affords another remarkable example of the great frequency with which the eye and the adjacent structures are injured, when only a single shot strikes a person. This singular liability of the eye being so frequently the seat of these injuries, has been noticed by Mr. Cooper and other writers, on injuries of the eye; of these, that which is produced by the bursting of a gun, and the lodgment of a portion of it in, or in the immediate vicinity of the orbit, is obviously the most formidable accident, and, in truth, the fact of the gunshot injury in the case we are about to discuss, not having terminated fatally, is in itself a matter of no small surgical interest.

Records of a few similar cases are to be found. One in which the result was like mine, favourable, is mentioned by Mr. Wm. Cooper, in his admirable work on injuries of the eye. The particulars of the case are quoted in Beck's Medical Jurisprudence. The case was one of a man who had his eye blown out by the bursting of a gun. The surgeon dressed it, and on the second dressing he perceived something hard among the injured substance of the eye. He found this to be metallic, and getting hold of it with his forceps, pulled it out, when to his surprise he found it was the breech of the gun which had been forced backwards by the recoil, and been jammed into the orbit. Notwithstanding this extensive injury which annihilated the eye, the man made a perfect recovery.

Dr. Keith, the deservedly eminent surgeon of Aberdeen, has also recorded a remarkable case of this sort, in which the breech of a gun was lodged for four months below the right eye, and across the nose.* The patient, James S., æt. 19, stated that while shooting on the morning of the 19th February, 1857, on the sea cliff near Aberdeen, his fowling-piece burst. "He stood stunned for a minute, and then fell on the ground quite insensible, and so continued for about half-an-hour. When consciousness returned he found himself in a farm-house, and then in the course of another half-hour was seen by a surgeon. He had bled very freely all this time from a large and deep wound in his face between his eyebrows, and just below that level into the very root of his nose. The wound extended from below the right eye across the root of the nose, and into the left orbit, lacerating the lower eyelid, and utterly destroying the left eyeball. The bones of the face proper seem to have been so far separated from the os frontis, that the patient is positive the surgeon applied one hand under his chin, and the other on the crown of his head, and pressed them forcibly together." On June 25, four months after the accident, the foreign body was successfully extracted by Dr. Keith. Before doing so the nasal bones had to be widely separated, and the piece of metal, which proved the breech of a fowling-piece, weighing two ounces and five drachms, and measuring two inches and a half in length, was extracted. The thick or saw bolt end entered first, and penetrated so far as to allow the very tip of the screw plate to be covered in by the skin of the nose. There was no profuse hæmorrhage during the operation. The case ultimately did very well, and an artificial eye having been adjusted, it was "difficult to discover that anything very serious had ever befallen him."

A somewhat similar case is detailed in the *Edinburgh Medical Journal*, for September, 1856, by Dr. James Young, of St. John's, Newfoundland. In this case the foreign body, which was a large coarse breeching of a common musket, was lodged in the right superior maxilla, and after remaining there for a period of eight years, was removed by Dr. Frazer, and the case ultimately did well.

A case in which this accident occurred, was under observation in the Richmond Surgical Hospital many years ago, under the care of the late Dr. Hutton. The case terminated fatally, as might well be expected, from the extensive nature of the injury, and the preparation of the fractured bones of the face and head, as well as the missile, are carefully preserved in the Pathological Museum which is attached to the hospital. The injury was caused by the bursting of a gun two hours previous to the patient's admission into hospital. A portion of the breech of the gun struck him over the superciliary margin of the left eye, producing a compound comminuted fracture of the skull. Several splinters of bone and portions of the stock of the gun were driven into the brain. We learn from the description of the preparation in the catalogue of the museum, that when he was admitted into hospital, the patient had rigors, the surface of the body was cold, pulse slow and weak, the respirations were sixteen per minute, and unaccompanied by stertor. He answered questions rationally, but in monosyllables. A profuse hæmorrhage followed the removal of some of the splinters of bone and wood from the brain. Symptoms of delirium set in shortly after the patient was admitted, and he was obliged to be forcibly restrained. Seven hours after admission his pulse was 70 per minute, and respiration without stertor. Upon the morning after the occurrence of the accident, he had delirium ferox; his pulse was 120 and feeble; he screamed so as to be heard in all parts of the hospital; his pulse rose to 150, and he died in thirty-six hours after the receipt of the injury. "The pupils were never unnatural throughout, and he had no convulsions; the left nostril was insensible to the most pungent odours." As this case is one of such absorbing interest, I feel that no apology is necessary for giving so many of its details, described as they are so graphically by my colleague Dr. N. W. Smith.

Any record, however brief, of this class of injuries, would be obviously incomplete, without reference to the celebrated case of Lieutenant Fretz, to which reference has been made by several writers, and the full particulars of which are given at length by Sir James Simpson, in his work "On Acupressure," as a case strikingly illustrative of the tolerance of living structures for the presence of metallic bodies. Sir J. Emerson Tennant in his work "On Ceylon," thus describes this classical case:

* *Medical Times and Gazette*, Oct. 23, 1858.

"Among extraordinary recoveries from desperate wounds, I venture to record here an instance which occurred in Ceylon to a gentleman while engaged in the chase of elephants, and which, I apprehend, has few parallels in pathological experience. Lieutenant Guard Fretz, of the Ceylon rifle regiment, while shooting at an elephant in the vicinity of Fort MacDonald, in Oorah, was wounded in the face by the bursting of his fowling-piece, on the 28th January, 1828. He was then about 32 years of age. On raising him, it was found that part of the breech of the gun, and about two inches of the barrel, had been driven through the frontal sinus, at the junction of the nose and forehead. It had sunk almost perpendicularly till the iron plate, called the tail-pin, by which the barrel is made fast to the stock by a screw, had descended through the palate carrying with it the screw, one extremity of which had forced itself into the right nostril, where it was discernible externally, whilst the headed end lay in contact with his tongue. To extract this jagged mass of iron thus sunk in the ethmoidal and sphenoidal cells was found hopelessly impracticable; but, strange to tell, after the inflammation had subsided, Mr. Fretz recovered rapidly, his general health was unimpaired, and he returned to his regiment with this singular appendage firmly imbedded behind the bones of his face. He took his turn of duty as usual, attained the command of his company, participated in all the enjoyments of the mess-room, and died *eight years afterwards*, on the 1st of April, 1836, not from any consequences of this fearful wound, but from fever and inflammation brought on by other causes. So little was he apparently inconvenienced by the presence of this strange body in his palate, that he was accustomed with his finger partially to undo the screw, which, but for its extensive length, he might altogether have withdrawn. To enable this to be done, and possibly to assist by this means the extraction of the breech itself through the original orifice (which never entirely closed), an attempt was made in 1835 to take off a portion of the screw with a file, but after having cut it three parts through, the operation was interrupted, chiefly owing to the carelessness and indifference of Captain Fretz, whose death occurred before the attempt could be renewed. The piece of iron, on being removed after his decease, was found to measure 2¾ inches in length, and weighed two scruples more than two ounces and three-quarters."

This remarkable case is also alluded to in Mr. Guthrie's "Commentaries on the Surgery of the war," and the full particulars of it were detailed to the Surgical Society of Ireland on January 18, 1845, by Dr. O'Callaghan, then surgeon to the 11th Huzzars. In the discussion on this case the late Sir P. Crampton, who presided, alluded to another case detailed by Mr. Rogers in one of the earliest numbers of the Medico-Chirurgical Transactions in which the breach of a gun penetrated the cranium, about the centre of the os frontis, lodged, and continued to remain in the substance of the brain, yet no one had any idea that any extraneous substance existed there until after six weeks, when a black, hard body appeared in the wound, which, when extracted, proved to be the breech of a gun, and which weighed several ounces. The man recovered perfectly without any loss of his faculties.

In the following case which came under my observation, the deformity was produced in precisely a similar manner, but in consequence of the alteration in the direction, the portion of the breech of the gun, striking, in the first instance, the superciliary ridge, its direction was altered, and it took a course downwards and inwards, and passing through the floor of the orbit, was finally lodged in the nasal fossa. The patient was thus saved from the consequences which would, in all probability, have proved fatal, as they did in the preceding case. The foreign body was successfully extracted about a week after the accident with much difficulty to the operator, and great pain to the patient—

Neil Ruddy, æt. 47, was admitted into the Meath Hospital on the 20th of January, 1865, having been recommended to me by my friend Mr. Henry Wilson. A glance at the accompanying chromo-lithograph, taken from a drawing executed by the late Mr. Connolly, gives a fair idea of the deformity under which this patient suffered, and also of the foreign body which was taken from the nasal fossa in which it had lodged. No trace could be found of the eyeball, which had apparently been completely enclosed, and at the lower and inner portion of the floor of the orbit, there was a large, somewhat circular or tubular, passage, about an inch and a-quarter in length, leading downwards, and to the floor of the right nasal fossa. There was no evidence of any diseased bone. The patient's health was very good, but he was greatly distressed by the continual draught of cold air passing through the passage leading from the orbit to the nasal fossa, and which rendered him liable to repeated influenzas. The patient's great desire naturally was, therefore, to have some operation performed which would have for its object the permanent closure of the passage, and consequent exclusion of the air. Considering that a plastic operation would have the desired effect, and my colleagues also fully concurring in this opinion, I recommended it to the patient, and he willingly complied. The operation was accordingly performed on January 22. I commenced by vivifying the edges of the eyelid, the upper portion of which was found drawn back, and adherent, to a great extent, to the roof of the orbit, with Langenbeck's two-edged bistoury, an instrument specially designed for vivifying the edges of the palate in staphylorraphy and rhinoplastic operations. This being done, I proceeded to transplant a piece of integument from the forehead, in order to cover in the defect. A portion of integument, somewhat oval in shape, and about two inches in length, was brought from above and to the inner side of the eyebrow down, covering the defect and made adherent to the vivified edges of the eyelids by numerous points of interrupted iron sutures. The operation, although it can thus be described in very few words, was an extremely tedious one, as those who are familiar with the practical details of plastic operations can, I am sure, fully understand.

Three weeks after the operation, the flap having become firmly united, and the wound in the forehead being completely healed, the patient left hospital and returned to the country. The drawing, by Mr. Burnside, of which a chromo-lithograph is annexed, showing the result of the plastic operation, was taken by Mr. Burnside twelve months after the operation.

I think the preceding case is well worthy of record in a two-fold point of view: in the first place, as affording an example of what is fortunately a very rare surgical injury, and also its being strikingly illustrative of the good results which may be obtained in such cases by plastic surgery.

Mr. TUFNELL observed that he had seen a case of injury arising from the bursting of an old gun which gave rise to necrosis. There was a fœted discharge of so intolerably offensive a nature that, although the individual lived for a number of years, he was obliged to withdraw from society, and, in fact, to become a hermit.

Professor MORGAN said that he had seen in the Queen's County Infirmary, a case of the kind referred to by Mr. Stokes, where the accident happened to a man who was out fowling with an ordinary percussion gun. The part which gave way was the hammer, and a portion of the breech to which the hammer was attached, about half an inch long, so that in fact the hammer was at right angles to the piece to which it was attached. It was lodged firmly in the os frontis, and a post-mortem examination showed that it had penetrated one of the anterior lobes of the brain. This man was carried home after the accident, remained at home about a fortnight, and came to the Queen's County Infirmary complaining of the point of the hammer that was projecting beneath the skin. It was proposed to get him into the Infirmary and try if this could be removed. He refused, however, and went home, but shortly afterwards his friends sought admission for him. Alarming symptoms had come on, and in the meantime, fiddling with the hammer, the man himself extracted the whole of the foreign body. He came into the Infirmary suffering from symptoms of abscess in the brain; he had violent rigors alternating with symptoms of insensibility, and he died within a month of the time from the occurrence of the injury. It was found that the piece of iron went through the frontal sinuses, that it had broken down the internal table of the skull, and got into one of the anterior lobes, causing the formation of an abscess about the size of a small orange in the interior of the brain. It must have been lodged at least half an inch in the lobe of the brain for a fortnight without giving rise to any serious symptoms.

Mr. WILSON said he could fully corroborate Mr. Stokes' statement as to the condition of the patient on whom he had operated so successfully. He had an opportunity of seeing the man when he first came to Dublin, and, as he did not engage in general surgery, he handed him over to the care of Mr. Stokes. It was an operation doubtful as to its success from the large extent of the cavity, and from the fact that it was difficult to find support for the margins of the wound carrying the sutures. You could look down into the nasal cavity,

especially with artificial illumination, and he thought the successful manner in which the deformity had been removed reflected the greatest credit on Mr. Stokes as an operative surgeon.

Dr. KENNEDY said there was one medical point in connection with Mr. Stokes' cases to which he wished to refer. The subject of aphasia had of late attracted much attention. But though many papers had been written about it, he could not remember that any one of them alluded to the effects of injuries close to the orbit, and at the same time implicating the brain. Yet, if there were any cases likely to establish the theory, for it could not be called more than a theory, that a certain portion of the left anterior lobe presided over the faculty of speech, it was these very cases. Some such he had a distinct recollection of having read. In these, however, the injuries arose from stabbing wounds perforating the orbital plate. In the case under the care of the late Dr. Hutton it was observable that while the patient could speak it was only in monosyllables.

Mr. STOKES said, in reply, that with regard to the liability occurring from injuries such as he had described, he could quite conceive how such a morbid condition might be induced, but in the case which came under his notice there was no evidence whatever of the disease having been induced by the accident; nor, indeed, was it noticed by any of the writers he had mentioned. He thought Mr. Tufnell having met with it was a matter of great interest. Had he known of the case described by Dr. Morgan he would certainly have mentioned it. The late occurrence of any affection of the brain after the receipt of such an accident was a point of much interest. A somewhat similar case was mentioned in the Surgeon-General's report of the surgery of the late American war. A man who had received an injury of the orbit was admitted to hospital, the wound granulated and healed up, and the man was discharged. Four months after the receipt of the wound the patient died. While walking one day in the street he suddenly became comatose, and died in a quarter of an hour afterwards. On making a post-mortem examination the ball was found lodged in the anterior lobe of the brain surrounded by an abscess.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 6, 1868.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS important election has terminated in favour of Mr. JOHN ADAMS, of the London Hospital, by an overwhelming majority. This result will surprise no one, notwithstanding the insinuations and suggestions put forward by certain journalists.

We yield to none in our sincere desire to see the college undergo reform. No one has spoken more plainly than we have against mere seniority being allowed to override all other claims. But we cannot possibly allow that seniority is in itself a disqualification for office, and we do not carry our warfare against seniority so far as to make us insensible of the merits of the senior Fellows.

A cry has been raised for more practical examiners, especially in anatomy. Now, Mr. ADAMS is not only a distinguished hospital surgeon of many years standing, but he is a very experienced teacher of anatomy. If not the oldest anatomical lecturer in the kingdom, he certainly is in the metropolis. For a whole generation and more he has taught anatomy, and from considerable experience we are inclined to think he is the most popular living teacher of that science. The idea of passing him over in order to select an anatomist from those lower in the list, could only have arisen in the mind of a person utterly ignorant of the position of the parties in the educational world, and, therefore, unfit to pronounce an opinion on the subject. The suggestion, therefore, was not only uncalled for, but impertinent. Our own views have been so frequently expressed, that in saying this was scarcely an occasion on which to run a tilt against seniority we incur no risk of causing any misunderstanding, and by acknowledging claims where they exist, we hope to gain more influence when we may feel compelled to speak in a different sense.

In congratulating Mr. ADAMS on his election by such a majority (17 to 4) we cannot help expressing our trust that he will always be found on the Liberal side.

From his antecedents we have every reason to hope that the profession will be satisfied with the manner in which he will discharge his duties. He comes to the Council, indeed, unpledged to any radical measures, but those who know him best feel sure that he will give every question an impartial consideration, and the liberal sympathies he has always evinced on general subjects furnish us with a criterion by which we may judge that liberal measures at the College will have his support.

ON MEDICAL HOODS.

IN our last number we gave an account of the visit of H.R.H. the Prince of Wales to the Colleges of Physicians and Surgeons in Dublin; and, in describing the visit of H.R.H. to the former College, we particularly noted the fact that the Fellows of that ancient Society wore the usual gown of an M.A., with the hoods of their several degrees.

Although not a matter concerning the public health, yet as an historical question, perhaps it may not be amiss to give our readers some information about these hoods, seeing that, even among well-informed persons, their ancient history and modern significance, are shrouded in almost complete obscurity.

The cowl or hood, in ancient and more correct Latin *cucullus*, and in mediæval monastic Latin *caputium*, was, and still is among some monastic orders, a covering for the head to protect it from the inclemency of the weather. It was a habit among the ancient Romans, being a coarse covering for the head, broad at one end for the head to go in, and then lessening gradually until it terminated in a point. It was thrown back on the shoulders when not in use. It is alluded to by Martial (Epigr. 14, lin. 6), and by Juvenal (Sat. 8, v. 145), and by other Latin writers.

This covering was worn by all classes without distinction; and its peculiar suitability for concealing the features, led to its adoption by monks and ascetics at a very early time in the history of the Christian Church. The ordinary dress worn in these times (and which, with slight modifications was continued in all civilized nations, to a compara-

tively late period), was the *cassock*, a garment with tight sleeves, which covered the wearer from the neck to the ankles, and which was conveniently fastened to the body by a girdle round the waist; and over this the gown and hood. The hood was sometimes attached to the gown, and sometimes separated from it, as we see in the elegant and graceful cloaks worn by some of the Irish peasant women at the present day. The cassock, which, when thrown open, became the modern coat, was the indoor dress, and, with the gown over it, was worn out of doors, and in cold weather.

The modern representative of the gown and hood in ordinary dress is the cloak with cape, or the over-coat. None of these were exclusively clerical dresses; but the clergy, on the conservative principles which have distinguished them at all times, continued to wear them when others had given them up; just as they wear white neckcloths now when their ordinary use has been discontinued by the mass of the laity. As the monastic orders multiplied and formed themselves into distinct orders, their hoods assumed a different fashion in cut, colour, and material. From the monks this difference passed to the cathedral and collegiate churches, and from them to the universities; so that at present the hood, varied in shape, material, and colour, is but a badge of distinction, serving to point out the academical degree of the wearer.

The use of the hood in ecclesiastical ministrations is enjoined by laws still in force on the clergy of the United Church of England and Ireland—(See Charles's "Irish Church Directory," for 1868, page 157.) That great authority Du Cange thinks that a part of these hoods, which originally fitted on the head, was afterwards detached, and finally became the square cap now worn in all colleges. A glance at old pictures, and even at common pictures of "the judicious Hooker" and George Herbert, will show the accuracy of this supposition. The stiff pasteboard part of the square cap is a comparatively modern addition to it.

The hoods of the University of Dublin are mostly the same, and we believe ought strictly to be identical with those used at Oxford. The hoods of the Queen's University are identical with those in use in Dublin. These are single or double. A single hood is a simple *cucullus* or *caputium*; a double hood is this, *plus* a cape covering the shoulders, and we see the "proper thing" worn every day by our judges. Correctly speaking, the inferior graduates ought to wear single, and the superior double hoods; but this distinction is now frequently overlooked, and bachelors sometimes wear a hood shaped, but not coloured, like that of a doctor.

The very general custom of wearing these hoods suspended over the glutæi maximi muscles, instead of wearing them on the shoulders is a vulgar innovation of ignorant robemakers, as may be seen by a look at any old picture (that of Sir P. Dun, by Kneller, in the Dublin College of Physicians for instance). The hood should be brought over the shoulders and hooked or buttoned on the chest like a cape; the long string ought to be wholly disused, for a hood is a covering for the head, not for the posteriors. Also the practice, which very lately has found countenance in Trinity College, Dublin, of doctors wearing their scarlet robes without their hoods, is incorrect. The hood is an integral part of the robe, which ought to be loosely closed in front by one button over the sternum, and have the hood for a cape and shoulder ornament, as we see it worn by judges and other officials. The facings of the robe ought to meet in front, and not be worn widely apart, as is now the general, but incorrect custom. In Dublin, and in Oxford, all doctors, except doctors in music, wear scarlet gowns and hoods with various coloured facings, according to the faculty. In Cambridge the D.D., LL.D., and M.D. hood is the same, we believe, while the distinction is in the gown. The real *full* dress of a doctor (and it may be seen at Dublin on Commencement days, as worn by Sir Joseph Napier, not as Vice-Chancellor, but as LL.D.), is a *cope*. This is not an exclusively ecclesiastical dress as many suppose, and it differs entirely from the chasuble, which is a strictly clerical ornament. The Scotch Universities, before the revolution of 1688, had curious hoods which have long disappeared, and which, after a considerable interval, during which there appears to have been little or no regular academical dress in Scotland, have been replaced by adopting hoods from the English Universities. Thus the Edinburgh D.D. wears the black and white hood of a Cambridge M.A. *non regent;* while the Edinburgh, and, we believe, the St. Andrews M.D., wears the handsome black and scarlet M.A. hood of Oxford, which is the same as that worn by an M.B. in Dublin. Before the revolution of 1688 the hoods of Aberdeen were the same as those of the University of Paris; St. Andrews as Louvaine; and Glasgow as Bologna; but since the European revolution, which began in France in 1789, Paris alone retains its ancient distinctive hood.

There are two new hoods recently adopted in Dublin University for new degrees—a Master in Surgery wears scarlet, bound with blue, and lined with white; and the Master in Engineering wears white tabinet, lined with green silk.

Notes on Current Topics.

Public Health.

THE weekly return of the Registrar-General is again in our hand, from which we find that the deaths registered in London, and in thirteen other large towns of the United Kingdom, were 2975 in the week ending on Saturday the 25th April, while the births amounted to 4758 in the same week. The annual rate of mortality was 24 per 1000 persons living, and the proportion was as follows:—23 per 1000 in London, 29 in Edinburgh, and 29 in Dublin; 23 in Bristol, 19 in Birmingham, 24 in Liverpool, 26 in Manchester, 30 in Salford, 24 in Sheffield, 25 in Bradford, 23 in Leeds, 15 in Hull, 25 in Newcastle-upon-Tyne, and 30 in Glasgow.

The deaths registered in London during the week were 1378, being less by 53 than the estimated amount, and 161 less than the number registered the preceding week.

The deaths from zymotic diseases were 278, the corrected average number being 315; 14 deaths from smallpox, 51 from measles, 27 from scarlatina, 4 from diphtheria, 57 from whooping-cough, 46 from fever, and 12 from diarrhœa were registered.

In the whole of London the deaths from fever were at the annual rate of nearly 8 in 10,000 persons living. 165 deaths occurred from phthisis, 169 from bronchitis, 68 from pneumonia, 70 from diseases of the heart, and 190 from diseases of the brain and nervous system. 2 persons died from intemperance, 4 from burns or scalds, 3 were drowned,

9 committed suicide, 9 were suffocated, and 2 killed by horses or vehicles in the street.

Annual Report of the Registrar-General.

THE notes and observations of Dr. Farr on the causes of death contained in the Registrar-General's Report for the year 1866, comprise many important particulars, which we judge will be interesting to our readers, and of which we give the following abstract. It will be remembered that the weather at the commencement of that year was very unpropitious, which, in connection with the cholera epidemic raised the death-rate above the average. It was found to be 23·6 per 1000 of the population, the average being not more than 22·4. The deaths registered in 1866 were 500,689. Of these 4993 were returned with no cause of death assigned, or a very indefinite one, and 3585 as "sudden death" or "found dead," making in all 8578 cases for which no specific cause was given.

From the report it is seen that 115,972 deaths or 23 per cent. of all the deaths with specified causes, were attributable to *zymotic* diseases; the proportion being 5·52 in every 1000 persons living, which is above the average annual rate of the previous fifteen years. *Miasmatic* diseases proved fatal in 110,059 instances, which is larger than the number registered in 1865, while the mortality from *enthetic* disease has been gradually on the increase from an average of 62 per million to 94 in the fifteen years, 1850-65, which was slightly decreased in 1866. Nearly a similar increase was presented in the *dietic* class of disease, but the *parasitic* group varied in average mortality.

In examining the returns of some of the more prominent diseases included under these heads, we find that small-pox, whether from disregard of danger or neglect of vaccination, has been much more fatal since 1862. The numbers were 81 per million that year, but for the four subsequent years they were respectively 293, 373, 309, 144. Measles in 1866 proved fatal in a larger number of cases than usual. The deaths from scarlatina and diphtheria were excessive, though less than in some previous years. Whooping-cough destroyed twice as many lives as in either of the two years before. The mortality from typhus was higher than in any year since 1854. The deaths from diarrhœa were 17,170, and from cholera 14,378, while those from syphilis have been increasing in regular progression from 957 in 1857 to 1662 in 1866.

There is but little variation in the death-rate from constitutional disease. The mortality from gout and cancer appears on the increase, and on the decrease from dropsy. Phthisis gives 55,714 deaths, which, together with 66,489 from bronchitis and pneumonia, form the largest proportion of the deaths registered in 1866. From local diseases there were 192,444 deaths; from old age, 28,546; from atrophy and debility in old and young, 31,097; and from violence of every kind, 16,915. In reference to the latter Dr. Farr remarks:—"Street accidents from horses and carriages kill more people in a year than railways; and falls of stone, and other substances which knock men on the head one by one in mines, are much more fatal in the aggregate than explosions."

Famine-Fever.

ACCORDING to official statements in the sixteen districts of Western Prussia, visited by famine, 3950 persons have been attacked with typhus-fever, of whom 1307 died, 2701 recovered, and 795 are still under treatment. The districts which have been most afflicted with the disease are Lötzen, 1307 persons attacked, 145 deaths; Johannisberg, 547 attacked, 84 deaths; while in the district of Heydekrag, in the midst of the other districts, not a single person fell ill.

Poor-law Medical Service of England.

WE present our readers with so full a report of the proceedings of the important meeting to which we last week devoted a long leading article, that they will not be disappointed at the brevity of our comments on this occasion. The meeting was undoubtedly one of the most important demonstrations that our oppressed Poor-law brethren have ever made. It is not surprising that Dr. Rogers should have been triumphantly re-elected President of the Association, and from what transpired, we may well hope that the meeting of London and Provincial Poor-law Medical Officers that he has announced may be a still greater success.

British Home for Incurables, London.

THIS institution, which is situated at Clapham-rise, is intended for the reception of approved candidates who are suffering from apparently incurable physical disease, as contra-distinguished from the incurably insane. There are two modes of admission, one by election, the other by payment of a sum equal to the cost of maintenance. The best medical advice is secured. Some may be wholly, and all are partially relieved, while comfort and succour in their outward circumstances are afforded to all who can avail themselves of the aid offered by this charity. It was founded in 1861, and held its anniversary in Willis's Rooms on the 29th of last month. Lord Carnarvon presided on the occasion, and powerfully pleaded on behalf of the home.

King's College Hospital, London.

THE anniversary dinner to aid the funds of this establishment was served on the evening of the 24th ult., at Willis's Rooms, King's-street, St. James's. The chair was taken by Mr. W. H. Smith, supported by a number of eminent gentlemen, among whom we may mention Sir W. Fergusson, the Dean of Westminster, Professors Plumptre, Johnson, Beale, &c. This is the only hospital within the limits of St. Clement Danes and the adjoining parishes which contain a population of 400,000, while patients, constantly on the increase, are also received from all parts of London. Last year, relief was afforded to 1781 in-patients, to 31,958 out-patients, and to 691 poor married women at their own homes. A strong appeal was made for subscriptions to increase the funds, and a sum amounting to upwards of £2000 was contributed during the evening.

St. Mark's Hospital, London.

ON Monday, 27th April, this hospital celebrated its thirty-third anniversary at the London Tavern, Bishopgate-street. The chair, in the absence of the Lord Mayor, was taken by Mr. Alderman Cotton. This is a most valuable institution, being established for the cure of fistula, prolapsus, and other diseases of the rectum. According to the statement of the chairman in proposing success to the hospital, it was customary before its foundation for other hospitals to send home patients afflicted with such diseases to die, but now, by the efforts of this society, they were sent home to live. Last year 1268 patients were admitted, 736 were

discharged cured, 218 were relieved, and 244 were still under treatment. There is room for 50 beds, but only 34 were made up in consequence of want of funds. One thousand guineas were subscribed in the course of the evening.

Earlswood Asylum.

THERE is a vacancy for a resident physician at this institution, Dr. L. Down retiring after ten years' service. We understand that those employed in the institution have taken advantage of this occasion to express to Dr. and Mrs. Down their great respect and esteem. Dr. Witherby is a candidate for the appointment.

Thankless Doctoring.

A GRAND result, the first towards the emancipation of the profession from the gratis-work system which consumes the personal energies and incomes of a great proportion of its members, has been effected by the united action of the Medical Officers of the Birmingham General Dispensary. It will be remembered that the claim for a small remuneration for the services to the poor which, for 15 years they had gratuitously discharged, was refused by the committee, although, as a matter of fact, the dispensary is so rich that the committee cannot dispose of the funds. Thereupon the Medical Officers resigned unanimously, and by since steadily adhering to their very proper and determinate course, have driven the committee to the necessity of appointing paid officers. Of course the late medical officers will be excluded, but they have gained a professional victory of the highest importance, and, by the same act, relieved themselves of thankless and onerous labours. We do not believe that the Birmingham General Dispensary can ever be worked by paid residents as efficiently as by the late staff, and we shall not be surprised, nor shall we thank them, when the committee are driven willy-nilly to accept the paid services of these gentlemen.

London Slaughter-houses.

No subject relating to the sanitary condition of our large towns is of more importance than the state and position of their slaughter-houses. Such places are undoubtedly necessary, for meat we want and must have. But there is no reason whatever why they should be suffered to be openly offensive, to generate disease, and to add to the virulence of those epidemics which, in unhealthy seasons, unhappily invade us. And yet it appears that within the bounds of the city alone there are fifty-eight of these places, in each of which from 60 to 120 head of cattle are killed weekly, and how many more of them there are in the adjacent suburbs it is impossible to say. No one who has looked into them can fail to perceive their obnoxious character; while, in addition, the difficulty of disposing at once of the blood, and fat, and offal, must without doubt render them a nuisance to any neighbourhood where they are found. The evidence of the Medical Officers of Health is decisive on this point; and it ought to be a serious question with the authorities of London especially, why such places are suffered to exist amongst us in their present form. Our continental neighbours have long ago come to a decision on the subject, and in the larger towns and cities of Scotland the inhabitants have banished them from their midst. How is it, then, that in London, the largest and the proudest city in the world, we are so reckless of propriety and health? True, there is at present no law which can touch the nuisance. Dr. Letheby, in 1866, said the Nuisance Removal Act does not apply to it, and nothing has been done since. But are there no persons sufficiently influential to put down all opposing and selfish interests, and to rid the metropolis of an evil so extensive, so prejudicial, and so disgraceful? Surely some means ought to be originated with a view of accomplishing this object.

Professor Roscoe's Lectures on Spectrum Analysis at Apothecaries' Hall.

ON Saturday last, at 2 P.M., Professor Roscoe, as previously announced in the MEDICAL PRESS AND CIRCULAR, gave the first of his course of six lectures at Apothecaries' Hall. The great hall was crowded with an assembly which listened with the greatest interest to the learned Professor's lecture. His subject is spectrum analysis, and his beautiful experiments drew forth frequent bursts of applause.

We congratulate the Apothecaries' Society on the success of their experiment to introduce a series of lectures, and we sincerely hope the plan may be extended and continued. They have every facility—a good hall, plenty of means for experimental demonstrations, and they may calculate on the good-will of every one interested in the progress of physical science.

The only inconvenience was the great heat on account of the size of the audience. If a little more ventilation could be introduced, it would be the only improvement we can suggest.

The fame of Professor Roscoe was sufficient to ensure the audience, but we cannot do other than thank the Society for the opportunity he had of bringing his favourite study before the profession, and their officers for the comfort they ensured by their arrangements.

Trade Dishonesty.

THE deliberate swindling conducted as a matter of daily habit and use by a certain class of tradesmen, in the matter of false weight, has been met in the most forcible manner by the praiseworthy and courageous conduct of some of the less conspicuous but more reliable of the London journals, by giving publicity to the names and addresses of those convicted of false weight cheating, and we observe with pleasure that the first step in an equally required and as useful reform in the matter of adulteration has just been taken. A baker named Smith has been convicted at Winchcomb petty sessions on the evidence of Mr. Horsley, the county analyst, of putting alum in his bread, and was fined £8 and costs.

If vestries and town councils were less culpably negligent in the discharge of the duties for the detection of adulteration, which the Legislature has unfortunately confided to them, the deliberate cheating which tradesmen defend as one of the necessities of competition, would be impossible. The conduct of the South London papers in honestly exposing, at the risk of making enemies, the persons guilty of these frauds compares most favourably with that of certain of the Dublin papers, who have gone so far in the race for popularity as to publish elaborate editorial defences of tradesmen in the suburbs who were brought to justice by the police for an exactly similar offence. Every trade friend so gained is compensated for by the loss of the confidence of a dozen of the public.

Public Immorality.

WE may call attention to a breakfast and conference to be held at Freemasons' Hall, Great Queen-street, W.C., tomorrow (Thursday), May 7th, in connection with the

working of the "National Association for the Suppression of Public Immorality."

The subjects proposed for conference upon this occasion are :—

1st. The best means for enforcing the law designed to check the public solicitation by prostitutes, in the streets of the Metropolis and provincial towns and cities.

2nd. To enforce the law designed for the suppression of houses of ill-fame, &c., in the Metropolis and provincial towns and cities.

The object of the National Association is to suppress, by every lawful means, the public exhibition of vice, and it is proposed to form branches in various towns.

The following statement issued by the Association displays the need for its operations :—

"It cannot be too widely or plainly known that prostitution has long since assumed all the phases and conditions of a *regular traffic*. Strange and even startling as the statement may appear, it is nevertheless a fact, that its organization is found to possess importers and exporters, procurers and procuresses, a species of literature and fine arts in the shape of grossly obscene books and photographs, in addition to the various plans and agencies necessary for carrying on this revolting trade. Another feature, perhaps still more destructive to the morals of the young, is the known existence of houses of ill fame, which serve the double purpose of brothels and 'reception houses,' where the youthful are encouraged and harboured with a view to their *immediate ruin*. Every facility is offered by the keepers of these dens of infamy to young creatures who are temporarily estranged from family and friends, or who may be in homeless or indigent circumstances. It must also be added, that this monstrous traffic is highly remunerative, and that many are known to be making large sums of money by keeping up a constant supply to feed its diabolical demands.

"Glaring and scandalous as the daily open exhibitions of immorality have become, its alarming progress would cease to excite surprise if the various ready facilities which are offered for the introduction to a life of shame were thoroughly understood by the public. Moreover, it is found that, notwithstanding the hundreds of young women who are annually rescued from the streets through the instrumentality of Refuges and Reformatories, the number still pursuing a life of shame and moral destruction yet maintains its frightful aggregate ; which is justly attributed to the unceasing operations of the pernicious agencies already named, and the perfect impunity with which they carry on the nefarious traffic, while laws specially framed to suppress it remain, through the *inactivity of the public, practically in abeyance.*"

THE Senate of the University of London has appointed as its new examiners in—Medicine—Dr. Russell Reynolds ; Anatomy—Mr. John Wood ; Physiology—Mr. Henry Power ; Materia Medica—Dr. Garrod.

A HASTY promise sometimes requires to be unexpectedly fulfilled, and many a person has had to redeem a personal pledge which he never dreamed he would have ever been called upon to meet. It would appear, however, that such drafts of honour, payable contingently on recovery from illness, are not negotiable, at least by the doctor; so that patients need be no longer deterred from affording a little promissory stimulus to their doctor by the fear that they may get well too soon, and be thereupon expected to pay. A Dr. Fogerty has lately sued a native Indian nabob for £7200 for attendance, basing his demand on the statement that the patient had promised him 5000 rupees over and above his fees, on condition that he was able to sit up and eat within eight days. The patient's brother, in his presence, raised this promise to £5000. The nabob sat up and ate within the prescribed time, but, after all, only made a jest of the extra fee. Dr. Fogerty did not see the point of the joke, and commenced an action for the amount, but learned to his cost that nothing but the regular professional fees were substantial in the eye of the law. We advise Dr. Fogerty in the couplet—

"Solvet dum dolet,
Nam sanus solvere nolet."
"Let him pay while he aches,
Or when cured he may not like to do so."

THE Chair of Physiology at Würzburg, vacant by the death of Professor Bezold, has been offered to Professor Pfleïger, of Bonn, who is very likely to accept it.

HER Majesty the Queen has given £250 to the building fund of the Edinburgh Royal Infirmary.

DR. THORNE THORNE has been appointed physician to the Royal Hospital for diseases of the chest.

SIR JAMES CLARK has had a severe attack of bronchitis, from which he is slowly recovering.

METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE quarterly meeting of this association took place last Wednesday evening, according to the announcement, and was largely attended. Some formal business having been transacted, the quarterly report of the council was taken as read. This important document opens with a correspondence between the Secretary of the Association and the Poor-law Board relating to the supply of medicines to the sick poor, in which the Board announce that although they "are of opinion that the supplying of medicines by the guardians as a distinct proceeding on their part is an expedient course, the Board have no power to terminate any existing contracts between guardians and their medical officers, except for the purpose of giving effect to the provisions of the acts with respect to the establishment of dispensaries."

The council, while participating in the disappointment which will be caused by this decision, note with satisfaction the admission that "the supplying of medicines by the guardians as a distinct proceeding on their part is an expedient course," and trust that a clause to give effect to it may be added to the Poor-law Bill now under the consideration of the legislature.

The report then states that the council, having carefully considered the subject referred to them of a *basis* for the equalization of salaries of medical officers in the London district, are unanimously of opinion that the "*per case*" system of payment is the most equitable for district medical officers; that the scale of remuneration should not be less than 3s. 6d. per case; medicines and dispensing to be paid for out of the Common Poor Fund; and that the salaries should be revised once in three years, and payment made upon the average annual number of cases attended in such period. For the workhouses they think no fairer scale of payment can be suggested than that which has received the sanction of the Poor-law Board in the parish of St. Marylebone, and which has already been commented on in our columns.

The Council then direct attention to the General Order of the Poor-law Board just issued, imposing "serious responsibilities and additional work" on workhouse medical officers without additional remuneration. This order has been previously remarked upon in THE MEDICAL PRESS AND CIRCULAR, and we have pointed out that the duties imposed by it must bring the Poor-law Medical Officers into collision with their guardians, or will be only too likely to make them responsible for workhouse mismanagement. While appointments are held by so uncertain a tenure as at present, the Council think it is somewhat hard that medical officers should be placed upon the horns of such a dilemma ; but with inviolable appointments, held direct from the central board, and with some approach to the rank and pay of inspectors, they admit that the new duties might be efficiently performed, and with much advantage to the service, by the medical officers. At the last general meeting a resolution was passed to the effect that the time occupied by the medical officer in desk work, especially in keeping the Workhouse Medical Relief Book, was so much time lost to the service of the sick poor, and a means of diminishing it was suggested to the end that he might be enabled to

devote the whole of his time to his medical duties. This resolution was forwarded in due course to the Poor-law Board, who have, to a certain extent, adopted in the new Order, the remedy proposed, viz.—the use of diet cards; but so as to increase the clerical work of the medical officer, already so onerous. The order will have the same effect throughout.

The Council next direct attention to the circular letter, requesting the co-operation of the guardians in discouraging the employment by medical officers of "unqualified" assistants to attend the sick poor. The Council consider that the practice of employing unqualified assistants is the fruit of necessity; the salaries usually awarded to medical officers not permitting of their engaging the services of legally qualified men. It must also be prominently remarked that during the last twenty years the union medical officers have, as a rule, acted in this matter in strict accordance with the implied authority of the Poor-law Board. In the official circular of the Board (April 4, 1848), occur these words:—"The Board are not prepared to say that in ordinary cases the medical officer may not employ, under his own superintendence, his assistant or *apprentice* to visit the sick paupers under his care; but they most distinctly point out that his doing so would not in any degree relieve him from any portion of the responsibility attaching to the discharge of the duties of his office." If, however, the district of a medical officer were not so extensive, or the cases not so numerous as to make it physically impossible for him—with due regard also to his own interests—to personally attend all his union patients, no doubt he might be fairly prohibited from doing any part of his duty vicariously. But as it is, either the districts and cases must be restricted to a manageable size and number, or such addition must be made to the salary of the medical officer as will enable him to employ a legally qualified assistant. In the case which probably gave rise to the circular of the Board, the district had double the population which can be legally assigned to a single medical officer without the special sanction of the Poor-law Board; and the cases were far too numerous to be attended to by any one or even two men. The guardians have recognized the difficulties of their medical officer, and granted him an extra allowance of £120 per annum to pay for the services of a legally qualified assistant. Will other boards do likewise; or, failing to do so, will they insist on their medical officers employing none but legally qualified assistants, in accordance with the recommendation of the Poor-law Board? If the latter course is adopted by them, this circular will prove the proverbial "last straw," and will so over-burden the ill-paid and already over-worked district medical officer, that the service will become altogether intolerable.

The report next alludes to the case of Dr. Rogers, on which we have said so much. It seems that after his dismissal Dr. Rogers tendered his resignation of the presidency, which he has so ably filled from the first formation of the Association. The Council, however, requested him to withdraw it for the time, so that its acceptance or otherwise might be left to the decision of the quarterly meeting; and to this course Dr. Rogers very kindly consented.

We have entered thus at length into the quarterly report, in order that all our readers may follow the important proceedings of the Association.

This report having been adopted, Dr. Rogers, the President, proceeded to make his statement, and to resign the office he has held from the commencement of the Association. He said—

When I last addressed you, I was under suspension, from the office I held at the Strand Union. I told you that I was prepared to meet any accusation the guardians could prefer against me if an opportunity was afforded me, and I demanded a public inquiry. This, I regret to say, the Poor-law Board refused, although my demand was supported by a vestry meeting of the parish in which I reside, and by a minority of the guardians, and several former guardians were prepared to give their testimony on my behalf. But I did not then tell you I had too much reason to fear I might not obtain justice at the hands of the permanent staff of the Poor-law Board; and that they would not be likely to spare any effort to deprive me of my appointment, their hostility having been repeatedly avowed to various persons, who communicated it to me; and, as an example of it, let me relate what took place after the public inquiry at the workhouse in June, 1866. On that occasion I gave evidence, on oath, which created deep dissatisfaction at head-quarters—my statements unavoidably reflecting as much discredit on the Central Board as on the guardians. Now, although in the course of my evidence I distinctly showed that I had repeatedly asked for various alterations, and that my applications had entailed much hostility upon me, which was confirmed by several members of the board who were present, and that the condition of the house was well-known to the guardians, yet Mr. Cane, in his summary of the evidence, threw on me the principal blame of the sad state of things which had prevailed, as appeared by the return moved for by Sir J. Simeon, which was published as a parliamentary paper, but without the opinion of the then President, Mr. Villiers, being attached to it, in which he (Mr. Villiers), wholly ignoring Mr. Cane's summary, did not allude to me in any way. (This was subsequently obtained from the Poor-law Board, on the application of Mr. John Storr, a guardian.) Be the object of this suppression of the decision of the Board, for such it was, what it may (it took place during the interregnum consequent on the formation of Earl Derby's government), the effect was to stimulate certain of the guardians to open hostility against me. A vote of want of confidence in me, founded on Mr. Cane's analysis of the evidence, was brought forward, but was not carried. Disappointed in this, the next step taken by the permanent staff to get rid of me was an attempt to persuade the guardians to appoint a resident medical officer, though they knew that my deputy lived next door to the house, and was always immediately available when wanted. The device was too transparent, and it failed. The winter passed away; but so resolute were they that directly after the Metropolitan Poor Bill became law they again wrote, and urged the guardians to appoint a resident, which, however, they declined to do. When I was suspended the guardians appointed an immediate neighbour, on the same night, to look after the house and the large parish of St. Anne's, Soho. This, when reported to the Poor-law Board, was not interfered with; and now, months after, they allow it to go on, though contrary to their own general order. Immediately after this the election of a new board took place, and several gentlemen who had befriended me declined to serve again, and serious illness incapacitated some of the most respectable and influential. During last summer, however, matters passed over fairly well, save that the guardian who afterwards moved my suspension induced his colleagues to pass a resolution which reflected, in an unjust and unwarrantable manner, on my professional skill, &c., and that, too, on grounds which were afterwards clearly shown to be absolutely groundless. In the month of October I felt it to be my duty to make complaint of the sad indifference that had been shown in the treatment of a pauper girl who had been sent up from Edmonton seriously ill. The facts were forwarded to the board, with a request that they might be inquired into by the medical inspector. This the board declined to do. They sent my statement to the incriminated officials at Edmonton, who generally denied the allegations. Their denials were sent to me; and, as they were utterly opposed to the facts within the knowledge of myself and other officers of the workhouse, I forwarded the complaint to the Poor-law Board. I subsequently learnt that the medical inspector, Dr. Markham, saw the girl at the house. He also examined the incriminated officials. I should like to know where the examination took place and in whose presence. Certain it is that he held no communication with me; nor did he take, or offer to take, the evidence of any of the officials at the workhouse, who could have testified to the truth of my statement. In consequence of the annoyance arising from the admission of casuals, many of them sick, within the walls of the workhouse, I was induced about this time to write to the Poor-law Board upon the subject, describing my difficulties. My letter was sent to the guardians, some of whom expressed great resentment at my having written, and an offensive resolution was proposed, carried, and sent to me. I called a day or two after on the medical inspector, Dr. Markham, and told him what had happened, which he listened to with apparent sympathy. Three or four days later, however, he sent to the guardians his opinion, formed privately mind, of the case of the pauper girl just referred to, in which he stated that my conduct was "most reprehensible" in making complaint on her unsupported statement—unsupported because he, in violation of all the rules of justice, had not taken the evidence of the officials who would have proved my charges. The guardians immediately suspended me, the guardian who moved it stating he had authority for saying that he knew the Poor-law Board wanted to get rid of me. Directly after my suspension was communicated to me I wrote to Earl Devon, as I felt satisfied there was no hope of justice from the permanent secretary. My letter was, however, sent by the Poor-law Board to the guardians, and subsequently made the basis for the charges

upon which the suspension was justified. At first the guardians were puzzled how to proceed, but the clerk suggested that the minutes should be searched. This was acceded to, and he was entrusted with the sole responsibility of extracting from the records of twelve years what he liked, without reference to explanation, denial, &c., from me. This individual had never evinced any kindly feeling towards me. I was so unfortunate as to incur his hostility some years ago. Being away from town, a groundless charge of neglect of duty was brought against my assistant, who acted as my deputy, by a late master of the workhouse, and was read to the board by the individual above referred to. Now it so happened that at the very time of the alleged default I had seen the master in company with this person nearly one hundred miles from town; and in the inquiry which took place this fact became known, and it then turned out that both these individuals had been absent from duty some days without leave; consequently the false charge fell to the ground, as they would have no knowledge of what had been asserted. He did not, however, extract this from the minutes. The statement and charges thus prepared were sent to the Poor-law Board, and subsequently forwarded to me for my observations thereon. I answered briefly. It was impossible to meet such assertions, so irrelevant and spread over twelve years of time in writing. I again asked for a public inquiry. My demand was silently refused. This was in accordance with the expressed wishes of the guardians. Had it been granted I could have disproved everything worthy of any consideration, but perhaps I should have shown that from the first there was a good understanding with the officials at Whitehall that my suspension would be confirmed. It may be asked, what grounds had the staff of the Poor-law Board for their unfriendliness to me? It is to be explained by the fact that it was well-known to them that I had suggested the formation of the Workhouse Infirmaries Association, whose labours had incidentally reflected such lasting disgrace on the board, and that I had warned Mr. Hardy against being led away, as he subsequently was, by the officials who surrounded him, and who, I knew, were leading him astray. In all this I may have been indiscreet, but I thought that if I failed not in the performance of my duty I should be unassailable. But it is now proved that such reliance was misplaced. I might have gone on, being 'antagonistic to the guardians," as they choose to call it, and continued 'wanting in deference and courtesy" to them, as long as I liked. I should have been secure had I not unavoidably brought deserved discredit on their office. They have now laid down the rule that no amount of zeal or ability will avail to preserve a medical officer's appointment if he should be so unhappy as to offend the permanent staff of the Central Board. We have heard something this evening respecting the regulations recently issued to workhouse Medical Officers. There is not one requirement which, at one time or the other, I have not brought under the notice of the Local board, and nearly always with the effect of exciting deep personal hostility. On three or four occasions during twelve years I have written to the Poor-law Board and requested their action and advice upon these matters, and, as a result, had hostile resolutions passed upon me, and, finally, I have been suspended and forced to resign. What security now do they offer to medical officers who will interpret these regulations literally? Absolutely none at all. If they neglect them, they will be censured and perhaps dismissed; if they perform them, they will be in equal danger—deemed "antagonistic and wanting in courtesy and deference" to the guardians. Truly we have fallen on evil days. Gentlemen, I must bring these observations to a close, but I cannot sit down without expressing my deep sense of obligation to those gentlemen and friends who have given me their sympathy and support, and especially those, including many members of Parliament, with whom I have worked so long in the Workhouse Infirmaries Association, and who, at a recent meeting, passed a resolution condemnatory of the injustice which the Poor-law Board had perpetrated in compelling my resignation without any open public inquiry into the truth of the charges; to the members of the council of our own Association; and, above all, to a fearless and independent press, both general and medical, which, with one remarkable exception, has given me the most generous assistance. I need not name that exception; you all know to which journal I allude, and those of you who are supporters of it will, no doubt, share the indignation I have felt at the attacks and calumnies of which it has been made the medium. The hand that should have been stretched out to help me struck me again and again when he thought I was down, consented to become the apologist of my persecutors, and sought to injure me in every way, both privately and professionally. Yes, it was my "own familiar friend, in whom I trusted," the colleague with whom I had worked and fought, and at whose service I had placed all my official experience, who thus "magnified himself against me"—who forsook me in the hour of need and turned against me the influence of a position of which he thus proved himself absolutely unworthy. I may well say, in the phrase employed by another medical journal, in commenting on this desertion, "*Et tu Brute!*" But I must quit this nauseous theme, and, as a concluding remark, let me advise you (although I do not see much prospect of any immediate beneficial result from your labours), to hold together as an association; avoid giving offence to your local boards, if possible, and await the turn of events, which, for good or evil, must arise from the dissolution of the existing and the election of another Parliament upon a more advanced and liberal basis (loud cheers). I now, gentlemen, resign into your hands the presidency of this Association.

At the conclusion of his speech, which excited a deep sensation, and was frequently applauded, Dr. Rogers left the chair, calling upon Mr. Godrich, vice-president, to assume the post, which he having done,

Mr. B. CLARKE, of the East London Union, rose and moved successively that Dr. Rogers be elected an honorary member of the association, and that he be invited to fill the post of president so long and ably occupied by him while still a medical officer.

Both propositions were received with loud applause, and carried unanimously, the whole meeting rising to second them.

Mr. GODRICH congratulated the association on what it had done, and Dr. Rogers on the noble stand he had made; and further, said that he saw no reason for observing the reticence of their friend who had not named the journal referred to at the close of his speech. It could not be too widely known that it was the *British Medical Journal*—the journal of the British Medical Association—to which Dr. Rogers had referred, or rather its editor, in terms of just indignation.

Mr. Godrich then vacated the chair, which was again taken by Dr. Rogers, amid loud applause.

Dr. ROGERS, in returning thanks for the honour of this re-election, said he was at first disposed to ask himself how he could consistently hold that office now he was no longer a Poor-law Medical Officer, nor ever likely to become one. But though dismissed by the Poor-law authorities, he was still connected with the treatment of the sick poor. He had lately been elected medical officer to the Newport Market Refuge and Industrial Schools for Friendless Persons, an institution which, though paid for and governed by voluntary efforts, helped to supplement the deficiencies of the Poor-law system, and as they knew, he had succeeded in his efforts to expose and remedy some of them, it was but natural he should gravitate there. He was happy to say his board of directors were all gentlemen, and did not need crown nominees to make them act honestly. He therefore thought he might resume the presidency.

The report of the council, of which we have given an abstract, having been adopted, the meeting proceeded to the other business.

Mr. EUGENE GODDARD, in an able speech, moved the first resolution, which was—

"That this meeting is of opinion: 1st. That the system of payment '*per case*' supplies the most equitable basis for the equalization of salaries of the London district medical officers; that the scale should not be less than 3s. 6d. per case, exclusive of the cost of medicines and dispensing; and that the salaries should be subject to triennial revision, payment being made upon the average number of cases attended annually: 2nd. That the scale of payment of the medical staff of the Marylebone Workhouse, approved and sanctioned by the Poor-law Board, is equitable, and that the adoption of a similar scale as the basis for the equalization of the salaries of the metropolitan workhouse medical officers generally, would give entire satisfaction."

The resolution was seconded by Mr. GODRICH, supported by Mr. B. BAKER, and carried unanimously.

Dr. ANSTIE moved the second resolution:—

"That this meeting, having taken into consideration the new General Order of the Poor-law Board imposing additional duties upon the medical officers of workhouses, desires to record its opinion that the effect of the Order, if rigidly carried out, will be to bring the medical officers into frequent collision with the guardians; and being further of opinion that some of the duties—especially those specified in Article 5—can be pro-

perly performed only by officers independent of the guardians, deems it advisable that such duties should be performed, as heretofore, by inspectors."

While regretting that some more immediate representative of the Poor-law Medical Service had not been called on to move this resolution, he felt that some reasons made him a not unsuitable substitute. He had seen much of workhouse management, and the duties of medical officers, and of the relations between them and their guardians. Upon the strength of his experience, he declared against the expediency of the new general order. He did not object to medical officers reporting on the sanitary condition of their workhouses—it was, indeed, a scandal that the opinions of the medical officers on questions of this kind were so seldom acted on. His objections were of another order. The new regulations imposed must entail much additional labour on the medical officers, whose pay is already discreditably low in proportion to their duties. If they do their duty as now laid down, they will have to condemn many existing abuses, and recommend many expensive changes. How will the Boards of Guardians receive such proposals? They will harass and persecute any man who may venture to do his duty, and make his life a burden. Will the medical officer be sustained by the Poor-law Board from attempts of the guardians to get rid of him? Witness the action of the board in relation to the President at the Strand Workhouse, and the still more recent compulsory resignation of Dr. Ransom, of Cambridge! In the event of any struggle arising out of this order between a medical officer and a board of guardians—the one anxious to do his duty by the sick poor, and the other to save the rates, the influence of the Poor-law Board will be exercised on the side of the guardians and against the sick poor and their solitary friend the doctor. He counselled them to united action, to resist this high-handed and unscrupulous dealing on the part of the Poor-law Board. Let them try to influence every Member of Parliament with whom they had any acquaintance, and persuade medical pupils to shun the service. He hoped the time was approaching when medical men would not be found to accept appointments from which honourable men had been driven, for no fault of their own but simply to please selfish and ignorant men, who chose to rid themselves of a medical officer, the tenderness of whose conscience threatened to tax their pockets inconveniently on behalf of the poor.

This resolution was seconded by Dr. BELCHER, and supported by several members.

Dr. RANSOM, of Cambridge, who was received with loud cheers, also spoke in support of it. He said he had been called upon to resign his office for having done just what the new order required. He had recommended distinct baths for inmates and casuals, proper wards for idiots, a little warmth and comfort in the casual wards—all necessary improvements but, of course, involving expense. One week he had been censured for signing the workhouse relief book for extras for persons engaged in labours of whom he knew nothing, and the next week again, censured for not doing the same thing. He had been officer for 25 years, and no complaint had been brought against him. When his case was brought before the Poor-law Board, they said he deserved a censure, but dismissal would be too harsh. Yet, to please the guardians, they had just afterwards called upon him to resign. He had been condemned by a newly fledged inspector of not a month's standing, insulted by the clerk in a manner that would have led to summary punishment had it occurred outside, and got rid of by the guardians to gratify a dislike founded on political grounds. (The greatest enthusiasm was produced by Dr. Ransom's speech.)

Dr. S. GIBBON (Medical Officer of Health for Holborn), though not a Poor-law officer, nor member of the Association, could not refrain from a few remarks in support of this resolution, especially as he had come to the meeting to make a statement, which he took this opportunity of doing. He denounced the new order as unjust, and an attempt by a side-wind to make the medical officers incriminate themselves, and then—the Board would hang them. It was most unjust, most unfair, most un-English. The statement he wished to make was that a deputation was to wait on Lord Devon the next morning, to press the necessity for efficient medical inspection, and he would take the liberty on that occasion of letting Lord Devon know what he and others thought of the new order which, without additional remuneration, imposed more duties on the already over-worked medical officers, and these duties such as pertained rather to the housekeepers, nurses, and to matron.

Dr. ROGERS before putting the resolution to the meeting, expressed his belief that this was another stratagem of the permanent staff to shield their colleagues, the lay inspectors, from further public reprobation for their, now proved, neglect of the most important part of their obligations, and for the performance of which the country paid them so liberally, by throwing the duty on the unfortunate Union surgeons. There was only one way to make the Poor-law Board act fairly, and that was to worry them by independent questioning in the House of Commons.

The resolution was then put and carried by acclamation.

Dr. R. FOWLER moved the next resolution :—

"That this meeting has heard with surprise the announcement of the receipt, by the several boards of guardians, of a circular letter from the Poor-law Board, on the subject of the employment by medical officers of legally unqualified assistants: That in the opinion of this meeting this practice of certain union medical officers has for the last twenty years received the implied sanction of the Poor-law Board itself, as witness the following passage taken from their official circular, dated April 4, 1848 :—'The Board are not prepared to say that in ordinary cases the medical officer may not employ under his own superintendence, his assistant or apprentice to visit the sick paupers under his care ; but they most distinctly point out that his doing so would not in any degree relieve him from any portion of the responsibility attaching to the discharge of the duties of his office.' That should it, however, be now the intention of the Poor-law Board to enforce the employment by the medical officers of legally qualified assistants, this meeting is further of opinion that it will be imperatively necessary for the Board to supplement such Order with a compulsory and considerable augmentation of the present very inadequate salaries of its several medical officers."

Having read the resolution as above, Dr. Fowler said:—The recent agitation, taken up by the public at large, and which has resulted in so much talked of change in the medical relief of the sick poor, seems quite to have ignored the very existence of poor-law medical officers. They, as well as the poor under their care, have indeed for years past had almost intolerable grievances, and yet it is even now considered that their backs are not quite sufficiently burdened. The agitation of bygone poor-law medical reformers recognised these grievances, and had, certainly, amongst its other objects, the direct benefit of their medical brethren—the Poor-law medical officers. Going no further back than Mr. Pigott's committee of the House of Commons in 1854—the result of the labours of Lord, of Hampstead, the late Dr. Hodgkin, and others—we owe to that the establishment of the principle of the permanency of our appointments—the most valuable banner of our little independence. In 1861, the indefatigable tenacity of purpose of Mr. Griffin, of Weymouth, led to the medical question being brought before Mr. Villier's select committee on poor relief. Mr. Griffin, Dr. Rogers, and myself, were examined, and one of the points we, one and all, strongly insisted on, was the immense advantage of the expensive drugs being found by the guardians. When considering its report, the committee divided on this very question, which was ultimately put as one of its recommendations ; and the consequence is that some few unions have conceded this boon. In these lucky instances there is not now that constant struggle betwixt humanity and the pocket as there must otherwise be in the person of almost every Poor-law medical officer. Now, sir, I am constrained to ask what direct benefit has occurred to the medical officers by recent agitation and its culmination in this metropolis—Mr. Hardy's Bill. I confess, sir, I was one who, in the early days of excitement, hailed its passing with delight, believing it was the thin edge of a wedge which, driven onwards, would lead to great results. On calmer and more careful examination, I found that all its clauses likely to be of any benefit to the medical officers were permissive and not obligatory, and through the former can always be driven with facility O'Connell's proverbial coach and six. In fact, it has been said that the Act was to relieve the guardians, not to benefit the medical officers. I shall, of course, be answered that the increased comforts of the sick poor must of a necessity be, at all events, of indirect advantage to the medical officers. Admitting the truth of this assertion to as much as it is worth, I must, sir, point out to you that these advantages, as far as at present intended, appear to be granted at the expense of the time and of the pocket of the Poor-law medical officer. In fact, we are in the position of the Israelites, who, when they complained to Pharaoh of their burdens, were deprived by him of the straw wherewith they made their bricks. The imposi-

tion of additional duties on the workhouse medical officers without any corresponding increase of their salaries, proves the correctness of my assertion. And this question of unqualified assistants is another back-breaking straw. This question is a very important one, because, in its existing form, it makes a direct appeal to an increased expenditure out of present very inadequate salaries. The employment of legally unqualified assistants demands a two-fold consideration. To what use have we put them; and why have we employed them? Now, sir, I have no hesitation in saying, and they who have any practical acquaintance with Poor-law medical officers will confirm what I say, that, as a rule, the medical officers, in so far as they have used their unqualified assistants in their public practices, have used them in the sense impliedly sanctioned by the Poor-law Board itself, *i.e.*, under their immediate superintendence and direction, not giving these gentlemen sole charge or responsibility of the paupers they occasionally visit. Of course the Poplar case will at once be thrown in my face, but I aver that this was an exceptional case, and, as an exception is required to prove a rule, so Dr. Gale's case forcibly proves one great blot on Poor-law administration, viz., the insufficiency of its means to the end in view. Sir, I think, we ought as men to take this opportunity of contributing a word of praise to a body of gentlemen indirectly stigmatised by this last circular letter of the Poor-law Board. There are many good men of mature age who, having gone through all or nearly all their hospital studies, are, from pecuniary or other circumstances, precluded from legally qualifying themselves. Such are sought after by Poor-law medical officers, and form most valuable assistants. Their practical knowledge is great, and if we could afford to retain them when qualified they would be worth treble their salaries. They are not locomotive in their desires, and when satisfied with their places, retain them long. Yet these are the men who the Poor-law Board says shall not attend the sick poor; whilst a few years ago it sanctioned a young apprentice, probably about fifteen, to "visit ordinary cases." It is this very properly and very naturally transitory servitude of legally qualified assistants which has, doubtless, been one objection to their employment. But the great and main objection has been the £ s. d. We shall be only too glad to employ legally qualified men. We shall thus be relieved from a great deal of moral responsibility and from much bodily fatigue. To do so we must have the wherewith to do it, which our present miserable salaries—in some instances but a few pence per case of week's duration—entirely preclude us from. It is not only a question of changing our present assistants. When the edict has gone forth from Gwydyr House, there will be required about 3000 qualified assistants. The market value of these gentlemen will of course proportionately rise; and, inasmuch as practical dispensing is not an invariable part of the present medical education, we shall be also put to the additional expense of employing dispensers. Our resolution records our surprise, and well it may. We have, as a body, for years given more personal attention to our duties than has been ever, or can be ever, adequately remunerated. When introducing, in attendance with many members of Parliament, a very large deputation of metropolitan Poor-law medical officers in 1859, to Mr. Sotheron Estcourt, the then president of the Poor-law Board, Lord John Russell remarked—"He felt sure the important subject which had brought them before him would meet with all the attention it deserved, and they themselves that respect to which the skill and ability which they devoted to the medical attendance of the sick poor of the metropolis so justly entitled them. Some years since it so happened that his own attention had been called to the subject of medical relief in various ways, and from that time he had remained convinced that the poor of the country obtained, in medical and surgical attendance, an article at a price far below what it was worth if paid for according to its real value in the market." We should, moreover, sir, be more than human if we worked ourselves to death in our public practices, to the total neglect of those private patients who are willing to properly remunerate us. In committee on the Metropolitan Poor Bill, Mr. J. S. Mill suggested that we should be debarred from private practice, adding, "It was eminently honourable to the profession that public duties were so well attended to as they were." Mr. Hardy, after pointing out the impracticability, in general, of getting men to take the duty if they were prohibited from private practice, and admitting that in a few cases of urgency brought before him the medical officer had given a preference to his private patients, added—"At the same time, he was bound to remark that in many cases the salaries were so small that the medical officer could not be much blamed for endeavouring to get money from other sources." This, sir, is the gist of the whole matter. We are but human. Our profession is our bread, and unless our salaries are considerably augmented, it will be practically impossible for us to afford to pay for legally qualified assistants. Underpaid work will always be underdone work.

The resolution was seconded by Dr. THOMAS, and supported by several gentlemen, one of whom, Dr. NICHOLAS, remarked that unqualified assistants were not only employed to attend the pauper, but also the private patients of their principals. Looking at the poor pittance paid he would ask if the pauper patient was to be treated better than the private patient who paid his attendant? By all means let the pauper be treated as well as the pay-patient, but was he to be distinguished by being treated better than those who paid for the medical officer's services?

In putting the resolution, Dr. ROGERS thought this was only an attempt on the part of the Poor-law Board to revive their fading popularity, and not dictated by any consideration for the interests of the sick poor. They had known for years that very few Poor-law Medical Officers could, out of their wretched salaries, pay for qualified help, but they had worked at this, they would still do so, but there was, first, a popular outcry in consequence of Dr. Gale's case; and, secondly, they wished their powers extended, and were, therefore, stimulated to issue this letter. When he was a Poor-law Officer he had for 11 years kept a qualified assistant; it was right for him to do so, but he felt the expense to be a great strain upon him; if, however, he had not done so, the Strand Board would have ousted him long since. The Clerk had frequently hunted him up to see whether his assistant was qualified.

The resolution was carried unanimously.

It was then suggested that a deputation should wait upon the Poor-law Board with the resolutions, but it was stated that the Board had already twice refused to see them. It was said the Board had laid down the principle that they would not admit their officers to any personal interview, as they stood in relation of employed and employers.

Another member suggested sending a memorial, but this was felt to be useless.

Dr. S. GIBBON was in the end requested, and at once consented, to take charge of the resolutions, and bring them forward the next day at the deputation to Earl Devon.

The proceedings terminated by a vote of thanks to the Council for their labours during the past quarter, and to the chairman for his conduct in the chair.

THE DEPUTATION TO THE EARL OF DEVON.

The deputation named in the foregoing report of the Poor-law Medical Officers' Association was received, according to the arrangements, by the Earl of Devon, on Thursday last.

Dr. Gibbon, according to his promise, brought under his Lordship's notice the resolutions that were confided to his care.

His Lordship confessed that the order placed the medical officers in a new position, but he seemed to think it better for them to report direct to the central board instead of to the guardians.

Further, his Lordship said he had several objections to increasing the number of medical inspectors, and further, inspection might be objectionable to the guardians. He added that he did not think the medical officers were adequately paid, and he should be glad to see guardians increase their salaries.

We regret not having space for a more detailed report, but the above confession of the President of the Poor-law Board, may be considered to be the result of the deputation.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE CARMICHAEL PRIZE ESSAYS.

ON Monday, 4th inst., the announcement of the successful candidates for the Carmichael Prize Essays, took place in the theatre of the Royal College of Surgeons, in the presence of the Fellows and the Licentiates of the College, as well as a large number of medical students.

Dr. ROBERT ADAMS, the President, took the chair.

Amongst those present were:—

George H. Porter, Vice-President; Wm. Colles, Secretary. Council—Drs. Wm. Hargrave, James Barker, Hans Irvine, Samuel S. Wilmot,

Richard G. H. Butcher, Rawdon Macnamara, Hamilton Labatt, Benjamin M'Dowel, Edward Ledwich, Wm. Jameson, Alexander Carte, James H. Wharton, G. W. Hatchell, Albert J. Walsh, Edward D. Mapother, William A. Elliott, Archibald H. Jacob, James Stannus Hughes, Secretary of Council, John Brennen (registrar), Drs. Cameron, Minchin, Quinan, Barker, O'Grady, M'Donnell, Stokes, Beatty, Cronyn, Guinness, Hewitt, D. Rogers, Rox, Gogarty, Gordon, Lynch, Benson, Shaw (F.T.C.D.), Kilgarriff, Nugent, John Owens, Croly, Ruckley, J. R. Kirkpatrick, George Owens, &c.

The PRESIDENT, in opening the proceedings, said that the meeting was assembled to carry into effect the object and spirit of the will of the late Mr. Carmichael. The President then read a lengthened extract from the will of the deceased, which stated that he had in his will of February, 1849, bequeathed £3000 to the College of Surgeons in Ireland, the interest arising from which sum was to be disposed of as follows:—Every fourth year after the investment of the sum in the funds of the College, a premium of £200 was to be adjudged by the Council for the best essay, and £100 for the second best upon the state of the medical profession in its different departments of physic, surgery, and pharmacy in Great Britain and Ireland at the time of the writing of such essays; the state of hospitals and schools of medicine, surgery, and pharmacy, and the state or mode of examination of testing the qualifications of candidates of the various licensing colleges or corporations in all these departments. Under these heads the authors should make such suggestions as occurred to them respecting the improvement of the profession with the view of rendering it more useful to the public, and a more respectable body than it is at present, and embrace within their observations the preliminary and moral education of medical and surgical students, as well as the best mode of conducting their professional studies. The consideration of the means for rendering the examinations as demonstrative as possible should likewise be the object of the essayists. To announce the successful candidates was now their business, and he would call on the secretary, Dr. Macnamara, to read the report of the judges.

Dr. MACNAMARA then read the following report:—"Gentlemen, we have most carefully read, studied, examined, and compared the five essays submitted for competition for the Carmichael Prizes, bearing respectively the following mottoes—viz., 'Delta A,' 'Salus Populi suprema lex,' 'E Spina culta fiat rosa,' 'Unite and prosper,' and 'Non nobis sed omnibus,' and now beg leave to submit for your consideration the following remarks as the result of our separate judgments and combined deliberations. It is the opinion of your judges that they could not recommend to your consideration for either of Mr. Carmichael's prizes any one of the first-named of these three essays—viz., 'Delta A,' 'Salus Populi suprema lex,' or 'E spina culta fiat rosa,' inasmuch as, though scattered through their pages are to be found some good, useful, and in some instances practical suggestions, still in their entirety they do not seem to be written in accordance with the enlightened spirit of the testator's bequest, nor even up to the present advanced position and requirements of our profession. With reference to the two last-named, the essay bearing the motto 'Unite and prosper' from the care and reflection which its author seems to have bestowed upon its composition, the generally correct views which it has enunciated, the useful suggestions he has given, and the apparent practicability in many instances of their being carried into effect, together with his adherence to the directions given by Mr. Carmichael for the guidance of competitors for his prize, to be the essay which we are most justified in recommending to the council for the honour of having awarded to it the first prize. With reference to the essay bearing the motto, "Non nobis sed omnibus," we feel justified in recommending the Council to award to it the second prize, inasmuch as though many of the author's suggestions may seem to be far in advance of the age, and, consequently, to be to some extent Utopian, still the work is evidently the production of a gentleman and a scholar, and of one earnest in his desire to raise the moral and social status of the medical man; and we doubt not that could his suggestions be carried into practice they would ultimately tend to elevate our profession, and thereby carry out the views of the beneficent founder of the prize fund.

The Registrar, subsequently handed the envelopes containing the names of the successful candidates to the President, who, in opening them, announced that the first prize essay, under the motto, "Unite and prosper," had been written by Dr. Mapother, and that to which the second prize had been awarded, "Non nobis sed omnibus," was the composition of Mr. Isaac Ashe, B.A., B.M., T.C.D.

Dr. MAPOTHER, in returning thanks, said he begged sincerely to thank the president for the kind terms in which he had spoken of his essay, and he would beg for a moment to explain why he did not feel disqualified from competing by reason of being a member of the Council of that College. He was aware that the adjudication would be alone intrusted to three members of the Council, and he was determined to take no part in the adjudication or selection of the judges. Therefore, he felt that he was not disqualified. He might further add that he availed himself of no private source of information to which he might have had access as a member of Council, and he endeavoured sedulously from the commencement to keep his authorship unknown. He did not suggest to the Council the doubling of the prizes as an interested party, and he would have very great pleasure, should any of the unsuccessful essayists question the decision, to bear the expense of printing their essays, and thus bring their cause into the highest court of appeal.

Mr. ASHE returned thanks for the warm expression of approval the adjudicators had used towards his humble merits. He cared more for the opinion of his profession and of the Council than he did for the prize itself. He would only say in addition that it was also an honour to be beaten by Dr. Mapother.

A cheer was then given for Dr. Mapother, and the proceedings terminated.

Correspondence.

CAUSES OF EMPHYSEMA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Please supplement my remarks on the causes of emphysema in your last number, with the fact that abdominal subcutaneous emphysema may be due to ileo-cœcal abscess. This was discovered by Dr. O'Ferrall, and is detailed in a masterly essay on the diagnosis of such affections in the *Dublin Hospital Gazette* of March 1st., 1854.—Yours truly,

April 30th, 1868. E. D. MAPOTHER.

THE HALIFAX MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Without descending to the spirit or acts of "Trade Unionism," the profession throughout the country are now recognizing the advantages of "co-operation," and are endeavouring to obtain for medical advice a more adequate "*honorarium*," and to restore some of that ancient dignity, which a too keen competition, combined with the love of self-aggrandizement, had reduced to a very low ebb. We see this feeling in the various societies which are springing up throughout the country, and in the exertions which they are making to raise the fees for club attendance with such good results, that if we are mindful of the motto, "Vis Unita Fortior," and if we are only true to ourselves we shall be able to obtain many of our wants. An association has been started in Halifax at the wish of the principal members of the profession, and up to this time its working has been followed by the happiest results. Its objects are—to protect the interests of its members, to suppress Charlatanism, and to advance the interests of the profession in every possible way. At the monthly meetings, papers are read or notes of cases given; out of the funds a subscription has been devoted to "Lewis's Lending Library;" the midwifery fees have been raised from 10s. 6d. to 15s.; and we have tried to raise the club fees, but as yet without success. We would wish to suppress the practice of medicine by unqualified persons, but we have come to the conclusion that all our efforts would be futile, until we have a change in some of the clauses of the medical act; and at the direction of the association, I now send you a report of some of the transactions at our last meeting. The members would desire to have an amalgamation of the different societies throughout Yorkshire, in order to secure more harmonious action on many questions which they believe of importance to the profession.

With your permission I will enumerate some of these:—

Firstly.—The return of a general practitioner to a seat on the Medical Council, for pure physicians and surgeons cannot form any adequate idea of their wants.

Secondly.—Changes in the Medical Act for registration is at present a farce, and this conviction has been forced upon us, by seeing this town infested with "Quacks," who are practising with impunity.

Thirdly.—Increase of vaccination fees.

Fourthly—To have our Poor-law officers better paid.

Fifthly.—To secure the return of medical coroners in every town.

We believe that by such a combination we should secure better results than by isolated action, and that if the unanimous voice of the profession was raised on these subjects, and a wholesome agitation commenced, the Medical Council might be stirred up to a more vigorous action on those questions which fall within their province.

Should any of the societies in Yorkshire be disposed to join with us for the attainment of the foregoing objects, I should be happy to hear from them on the subject, and to lay their letters before our Society.—I am, sir, yours, &c.,

THOMAS M. DOLAN, L.R.C.P.,
Secretary to the Halifax Medical Association.

Medical News.

UNIVERSITY OF CAMBRIDGE—NATURAL SCIENCE SCHOLARSHIPS. — St. Peter's College, Cambridge, offers a scholarship of the value of £60 per annum for natural science. The Examination (in Botany, Chemistry, and Comparative Anatomy), will commence on Tuesday, June 9th. It will be open to all students who are not already members of the University, or who have not begun to reside. Candidates must send in their names to the Rev. J. Porter, St. Peter's College, Cambridge. Four scholarships have lately been given in this University—one of the value of £80 a-year, in Trinity College, to Mr. Prior; two in St. John's College, £50 a-year each, to Edmunds and Garrod; and one, £40 a-year, in Downing College, to J. C. Sanders.

LIST of Entries for the Branch Medical Council (Ireland) for the month of April, 1868 :—

William Thornley Stoker, 4, Orwell-Park, Rathgar, co. Dublin, Lic. R. Col. Surg. Irel., 1867; M.D., Q. Univ. Irel., 1866. John O'Neill Sisk, Fermoy, co. Cork, M.D., 1867, and M.Ch., 1867, Q. Univ. Irel. James George Wyse, 1, Anna Villa, Phibsboro', co. Dublin, Lic. Apoth. Hall, Dub., 1867. George Myles, 26, George's-street, Limerick, Lic. R. Col. Phys. Edin., 1866; Lic. R. Col. Surg. Edin., 1866; Lic. Apoth. Hall Dub., 1866. Neill Farren, Straid House, Clonmany, Derry, Lic. Fac. Phys., and Surg. Glasg., 1867. Arthur Thomas Birney, 26, Middle Gardiner-street, Dublin, Lic. K. Q. Col. Phys. Irel., 1868; Lic. R. Col. Surg. Irel., 1867. Andrew M'Munn, Ballymote, co. Sligo, Lic. K. Q. Col. Phys. Irel., 1868; Lic. R. Col. Surg. Irel., 1868. John Joseph Neville, Macroom, co. Cork, Lic. R. Col. Phys. Edin., 1867; Lic. R. C. Surg. Edin., 1867.

DIGGS LA TOUCHE—CHARLES LESLIE—LUKE JOHN M'DONNELL—RICHARD MANDERS—HUGH O'CONNOR—THOMAS PIM—GEORGE PIM—PATRICK SWEETMAN—HENRY THOMPSON—RICHARD WILLIAMSON.

FIRE DEPARTMENT.

THE Directors call the attention of the Public to the new Table of Life Rates, in which a considerable reduction has been made, particularly in the younger lives for whole term, affording to the Assured the utmost advantage consistent with security.

A Quinquennial, instead of a Septennial, division of Bonus has been adopted; the first Bonus averaged Two per Cent. per Annum on the Sum Insured, and the result of the Actuary's Investigation for the Five Years ended 31st December, 1862, is still more favourable, as shown by the following Example :—

Date of Policy.	Age.	Amount Insured.	Annual Premium.	Bonus Added Dec. 1857.	Bonus Added Dec. 1862.	Total.
		£	£ s. d.	£	£	£
1851	58	500	32 5 0	86	96	182
1852	50	3000	136 2 6	407	416	823
1853	40	1000	32 18 4	97	107	204
1854	55	600	32 11 0	50	90	140
1855	57	500	29 9 2	29	77	106

At the option of the Assured the Bonus may be commuted for a reduction in the Annual Premium, or a payment in money.

The Assured are allowed, in time of peace, to pass from one port in Europe to another, in steam or other decked vessels; and residence in other parts of the World allowed on very moderate terms.

No charge for Life Policy, Stamps, or Entrance Money. Age admitted at any time, on satisfactory proof of same being furnished. A liberal return of premium allowed for surrender of Life Policies, on which Four Years' premiums have been paid. Loans granted on Life Policies to the amount of their surrender value. Thirty Days allowed for renewal of Life Policies.

FIRE INSURANCES at the Lowest Rates. Fifteen days of grace allowed for payment of Fire Premiums.

MARINE INSURANCES at current rates of the Day.

In addition to security, not exceeded by any similar institution in the empire, the utmost facility is afforded in transacting Insurance business, from the fact of the Head Office being in Dublin, and the daily attendance of a Commitee of Directors for the purpose.

By Order, JOSEPH TODHUNTER, Secretary.

The business of this Company is restricted to Ireland.

LIQUOR CHLORODYNII.
TEASDALE'S.

THIS Preparation will be found to supply a want, very generally expressed, a cheap and really good Chlorodyne. ½ lb. and 1 lb. Sample bottles, 5s. and 9s., sent, carriage paid, to any part of England.

Prices :—2 oz., 1s. 6d.; ¼ lb., 2s. 6d.; ½ lb., 4s. 6d.; 1 lb., 8s. 6d.; 3 lbs., 24s.; 6 lbs., Winchesters, 45s. each. Through all Chemists.

Sole Manufacturer, G. TEASDALE, Chemist, Bramley, Leeds.

For select Medical Opinions, see Advertisement in
MEDICAL PRESS AND CIRCULAR, January 25th, 1868.

JAMES'S FEVER POWDER, 4s. 6d. per bottle,
Packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

THE SCIENTIFIC WONDER.

THIS INSTRUMENT has a clear magnifying power of 32,000 times, shows all kinds of animalculæ in water, circulation of the blood, &c., &c., adulteration of food, milk, &c., and is just the Microscope that every Surgeon, Dentist, Schoolmaster, Student, and Working Man should have.

It is pronounced by the press (and all scientific men who have seen it) to be the best, cheapest, and most simple microscope ever invented.

It has twenty times the power of the Coddington or Stanhope Microscope, and is twice as good as the celebrated Rae Microscope (which has been awarded so many prize medals), as may be inferred from the following letter received from Mr. Rae himself:—

"Carlisle, December 12th, 1867.

"To Mr. McCulloch, Philosophical Instrument Maker.

"Sir,—Having seen some of your Diamond-Plate Lenses, I write to ask your terms for supplying me with the same per 20 gross, as I consider them superior to mine.—Yours, &c.,

"Rae & Co., Opticians, Carlisle."

I beg to inform the public that I have no agents anywhere, and all pretended agents are impostors. The above Instrument can only be had from me, in Birmingham. Those at a distance who care for instruction and amusement can have it safe and free by sample post, with book of full instructions, on receipt of 32 postage stamps. Samples sent abroad two stamps extra.

All persons wishing further particulars and testimonials must send stamped and addressed envelope.

ADDRESS—

A. McCULLOCH,
Philosophical Instrument Maker,
No. 18, BLUCHER-ST., BIRMINGHAM.

FOURTH LECTURE ON FOOD.

PRESERVATION OF FOOD.—UNWHOLESOME AND ADULTERATED FOOD.

(Continued from page 394.)

3RD. *The preservation of food by cold* is a well-known process, for every one is acquainted with the fact that meat will keep for a long time in the winter season without deterioration; but the extent to which this preservative power may be carried is not well-known. Animals, we are told, have been found in a perfect state of preservation in the frozen earth of the arctic regions, where they must have been buried for centuries. Last year, indeed, a communication was made to the Royal Society, by Dr. Carl von Baer of the fact, that the entire body of a mammoth was found in the frozen soil of arctic Siberia. How long it had been so preserved it is hard to conjecture, but it must have been there for ages. Another good example of the preservative power of cold was observed in Switzerland in the autumn of 1861, when the mangled bodies of three Chamounix guides were found at the lower part of the Glacier de boissons. The flesh of the bodies was perfectly preserved, notwithstanding that 41 years had elapsed since the unfortunate men lost their lives. They were carried away by an avalanche from the grand plateaux of Mont Blanc in the month of August, 1820, while attempting to ascend the mountain with Dr. Haimell; and no trace of them was discovered until the corresponding month of 1861, when by the slow descent of the mountain ice their remains were brought to the lower glacier. So well is this preservative power of cold known to the inhabitants of Russia, Canada, and other northern climates, that it is a common practice to slaughter fat animals on the approach of winter, when fodder is getting scarce, and to preserve their carcasses by burying them in the ice or frozen earth; and they are thus preserved from the middle of November to the early part of May. We also have a practice of packing salmon in ice; and we receive game and poultry from America, and send the like to India in boxes surrounded with ice. The application of this method of preserving food is almost without limit, for not only can we obtain a stock of ice for such a purpose in the winter season, but it may be brought to us at any time from colder regions of northern Europe, or it may even be manufactured at a cost of less than half a guinea a ton. There is a machine of Mr. James Harrison, of Australia, made in this country, which is said to be capable of producing 8000 lbs. of ice a-day, at a cost, including all expenses, and with a good margin for profit, of ten shillings a ton. Why, therefore, may we not use ice in the summer months for the preservation of food? Dealers could easily provide themselves with close rooms containing ice, in which the food might be placed; and we, ourselves, might use ice-boxes more commonly in our households. It might interest you to know that the first patent for the preservation of food in this manner was granted to John Lings in 1845.

Again, a temperature of from 200° to 212° will also arrest putrefcation; and joints of meat may be preserved for a time by dipping them every now and then in boiling water.

The 4th and last method of preserving food is *by the use of chemical agents, called antiseptics*, which act by destroying infusorial and fungoid life, and by forming compounds which are not prone to decay. Foremost of these is *common salt*, which has been used from the earliest time; but it is not a good agent for the preservation of meat, as it renders it tough, gives it a bad flavour, extracts the soluble constituents of it, and makes it hard and indigestible. The process, however, is much better managed at the present time than formerly, when the hard junk of the navy was the common diet of our sailors; and, considering how easily it is applied, it is not surprising that it is almost universally practised. In many parts of England and Wales it is the custom of the better classes of agricultural labourers to fatten a pig during the summer, and kill it and salt it for the winter. Hams and tongues are treated in like manner, and so are fish, when they are plentiful among the inhabitants of our coasts. As far back as 1800 a patent was granted to Mr. Benjamin Batley for curing and preserving herrings and sprats by salting them; and it would seem that his process was very successful, for in the following year he obtained a patent for the like treatment of other fish. The dainty *caviare* of the Russian is nothing but the salted roe of the sturgeon. Even vegetables may be preserved in salt and water, as in the case of olives. Other saline substances, as saltpetre, acetate of ammonia, sulphite of potash

or soda, muriate of ammonia, &c., are also good preservative agents, and are the subjects of several patents. Here is a specimen of meat preserved by wetting it with a solution of one part of acetate of ammonia and nine of water; and here another, which has been similarly treated with a weak solution of sulphite of soda. It is only necessary to brush the solution over the surface of the fresh meat, and when dry it will leave the meat in such a state as to resist decay. Instead of covering the meat with the solution, it may be injected with it, as in the patents of Long (1834), Horsley (1847), Murdoch (1851), and others.

After meat or fish is salted it is frequently dried and smoked by exposing it in close chambers to the vapours of smouldering peat, wood, straw, &c., and in this manner it becomes impregnated with the dark brown empyreumatic oil of the burning wood. The chief agent concerned in the preservation of food thus treated is the creosote of the empyreumatic oil, and this it is which gives the food a smoky flavour. A like effect may be produced by dissolving the creosote of wood-tar in vinegar, and brushing it over the salted joint. The creosote of coal-tar *(carbolic acid)* is also a powerful antiseptic, but its flavour is not agreeable, and, therefore, it is not used in the preservation of food; although it is extensively employed in the form of coal-tar, dead-oil or creosote, in the preservation of wood, canvass, &c.; and the perfection of purity to which it is now brought by Dr. Crace Calvert, and other manufacturers, encourages its use in medicine and surgery.

Spirit of wine and *vinegar* are other preservative agents which owe their antiseptic power to their destructive action on infusorial life, and to their combining with the albuminous constituents of food. Cherry-brandy and pickles are good examples of this.

Lastly, I may state that the fumes of burning sulphur (*sulphurous acid*) are very powerfully antiseptic; and many patents have been taken out for their employment in the preservation of food. In the spring of 1854, Laury obtained a patent for it, the gas being introduced into the vessel containing the substance to be preserved. Later in the same year Bellford received provisional protection for the use of sulphurous acid with about one-hundredth its volume of hydrochloric acid—the object being to prevent the sulphurous acid combining with the alkaline salts of the meat, and so giving it an unpleasant taste. The acids were to be used in solution, and the meat immersed in it for twenty-four hours. In the following year (1855) there were three patents—those of Brooman, Demait, and Hands, for the use of the acid in a gaseous form; and in the specification of Demait it was directed that the substance should be preserved by hanging it up in a chamber and exposing it for a time to the action of the gas. Professor Gamgee has revived this process in a recent patent, and with certain modifications. He recommends, for example, that the animal should be made to inhale carbonic oxide gas, and when it is nearly insensible, it should be bled in the usual way. After the carcass is dressed, it is to be suspended in an air-tight chamber, which is to be exhausted of air, and then filled with carbonic oxide gas, to which a little sulphurous acid has been added. It is to remain exposed to these gases for twenty-four or even forty-eight hours, and is then to be hung up in dry air; after which it is said that the carcass will keep for many months without perceptible change in taste or appearance. The process has been tested by killing meat in London, and sending it to New York; and after the lapse of from four to five months the meat has been pronounced good by a practical butcher. I am very much inclined to think that the real preservative agent is the sulphurous acid, and that the highly poisonous carbonic oxide gas might be advantageously excluded from the chamber.

And now, in leaving this part of the subject, I cannot refrain from saying that the history of these patents for the preservation of food affords very striking instances of the necessity for an amendment of our patent laws; for not only is there a frequent disregard of all scientific principles in the construction of the patents, but in many cases there is also a total disregard, or else profound ignorance of what has already been done in the matter. Repetitions, therefore, occur again and again of the same process, nearly always imperfectly specified; and, on the other hand, the most ridiculous propositions often assume an importance as if for no other object than that of obstructing invention. Out of the 121 patents for the preservation of food, which I have had an opportunity of examining, there are hardly a dozen that can be regarded as either useful to the community or profitable to the patentee.

I come now to the last division of our subject—namely, that which relates to the sale and use of *unsound* and *adulterated food;* and perhaps the most important of this kind of food is *bad meat*—that is, meat which is unwholesome on account of putridity or disease. Food of this description has always been a subject of legal prohibition. Among the Jews the prohibition dates from the time of Moses, who is supposed to have received from the Lord during his sojourn upon Mount Sinai, certain oral commandments respecting the slaughtering of animals for food, and the examination of their bodies for disease. There is no account of these commandments in the written law, but they were evidently communicated to the people of Israel by Moses, for he says, "thou shalt kill of thy herd, and of thy flock, which the Lord hath given thee, *as I have commanded thee*—(Deut., chap. xii., v. 21). It is presumed, therefore, that these instructions were very specific, and that they have been practised by the Jews from that time until now. The Hebrew law is that no flesh shall be eaten, except of animals that have been killed and searched, or examined, by the officer *(bodek)* appointed for that purpose; and the most precise rules are laid down for his guidance in these matters. In fact he is bound by very solemn obligations to declare of every animal that he kills, whether the flesh is proper to be eaten *(caser)*, or is unfit for food, by reason of its being diseased or torn (*trefa*). This expression appears to have been derived from an ordinance of Moses, that no flesh should be eaten that is torn in the field (Exodus, chap. xxii., v. 31); the word torn (*trefa* or *terefa*) being supposed, according to the traditions of Hebrew sages, to apply not only to animals torn in the chase, or by wild beasts, or by the bungling act of the butcher, but also to those affected with any disease that would shorten their lives; and as it is thought that such disease is always indicated by the condition of the lungs, the utmost care is taken by the searcher or *bodek* in the examination of these organs. His rules or instructions for this purpose are very strict; but generally it may be said that he condemns as unlawful, or unfit for food, the flesh of all animals in which the lungs present the following appearances:—Certain deficiencies, excess, or displacement of the lobes; adhesions or false membranes; tubercles, or abcesses containing matter or opaque water; discolourations which do not disappear when the lungs are inflated; ulcers, holes, and abrasions letting air through them; consolidations that are impervious to air, and rottenness of tissue. Many of these are, no doubt, unimportant evidences of disease, and therefore, although the flesh of such animals is rejected by the Jew, it is freely consumed by the Christian. The Jews, indeed, make a sort of bargain with the unorthodox butcher, to take only such animals, when slaughtered by their officer, the bodek, as he considers lawful, and the rest are sold to the public. I dare say this has been the practice at all times, for there are frequent references to it in our legal and domestic records. In *Liber albus*, for example, there is a memorandum to the effect that on the 24th of June, 1274, certain discreet men of the city were summoned before the king's council, to answer the question as to what was done with the unclean flesh of the Jews, and whether it was lawful for Christians to buy and eat the same. Their answer was, that if any citizen bought such flesh of a Jew, he would be expelled, and if convicted by the sheriff he would forfeit such flesh, which would be given to lepers or dogs, and he in addition would be heavily fined. To which the council replied that they commanded them in the king's name to have the custom

strictly observed. I fear, however, from the legal records of *Liber albus*, that less attention was paid in those days to the sale of diseased meat than to that of putrid meat; for, on examining the accounts of the citizens made and rendered in divers courts of the king, I find that while "judgment of pillory" is recorded in twenty-one cases for selling putrid meat, poultry, or fish, there is not a single instance of a like punishment for selling the unclean meat of the Jews.

In ancient Rome there were overseers appointed to examine the meat in the public markets before it was sold, and butchers were often fined for neglecting the law in this respect. Mr. Charles Reed has given us an example of this from the *Acta Diurna*, or Roman gazette of 585 years after the building of Rome, which, when translated, runs thus:—A. U. C. DLXXXV. Fourth of the kalends of April. The fasces, with Licinius, the consul, and Lertinus, ædile, fined the butchers for selling meat which had not been inspected by the overseers of the markets. The fine is to be employed towards building a chapel to the temple of the goddess Tellus.

In modern times, also, severe regulations have been made in all the States of Europe for the government of this matter, and in many cases particular instructions are given as to the kind of disease which renders meat unfit for human food—it being the practice to examine the animal while alive, and its carcass when dead. This examination is entrusted to properly-qualified officers, who are bound to condemn diseased and putrid meat, as well as the flesh of animals that have died otherwise than by the hand of the butcher; and no meat can be sold until it has undergone such an examination. In this country, however, although there are laws prohibiting the sale of unsound and unwholesome food, yet there is no provision for the systematic inspection of meat, even when it has reached the public shambles. All that the law declares is, that the local authority may, if it pleases, appoint an officer for that purpose; and as the appointment would cost money, and is not compulsory, it is rarely made. Practically, therefore, there is, except in a few places, an almost unchecked traffic in diseased and unwholesome meat; and the worst descriptions of it are generally sold to the poor at night.

Our forefathers made stringent rules to prevent this; for, among other things, they ordained "that butchers shall close their shops before candle-light, and shall not sell flesh meat by light of candle" *(Liber albus)*.

Within the city of London the inspection is performed as carefully as it can be, but, nevertheless, amidst the confusion of business in the early hours of morning, a great deal of unsound meat escapes the notice of the inspectors. In fact, if it were not for the assistance afforded to them by the salesmen of the markets, it would be absolutely impossible to check to any large extent the sale of unwholesome meat; for, in the three markets of the city—Newgate, Aldgate, and Leadenhall, as much as 400 tons of meat are sold daily. It is brought from all parts of Great Britain and Ireland, as well as from Belgium, Holland, and France, and even from the ports of the Baltic. Of this, a large quantity is diseased, and it comes chiefly from our own country towns, where it is a common practice to forward to London everything that is unsaleable at home. I cannot tell what is the actual proportion of bad meat to good, but we seize and condemn about two tons a week, and this is in the proportion of one part to 750. Last year the amount of meat condemned as unfit for food was nearly 129 tons, and in the preceding year it was more than 152 tons. In fact, during the seven years which have expired since the inspectors were appointed under my recommendation, we have seized and destroyed 1,567,810 lbs., or just 700 tons of meat as unfit for human food. Of this quantity, 805,653 lbs. were diseased, 568,375 lbs. were putrid, and 193,782 lbs. were from animals that had not been slaughtered, but had died from accident or disease. It consisted of 6640 sheep and lambs, 1024 calves, 2896 pigs, 9104 quarters of beef, and 21,976 joints of meat: besides which, there were also seized and condemned in the City markets on account of putridity 19,040 head of game and poultry, 207 quarters of venison, and above seven millions of fish, together with thousands of bushels of whelks, shrimps, periwinkles, &c.

It is to be regretted that in the various Acts of Parliament which relate to the condemnation of unsound meat, there are no special rules for the guidance of the officers appointed to investigate this matter—there being only a very loosely worded general provision to the effect that the medical officer of health, or the inspector of slaughter-houses, or the inspector of nuisances, may, at all reasonable times, inspect and examine any animal, carcass, meat, poultry, game, flesh, fish, &c., exposed for sale, or deposited in any place for the purpose of sale, or in preparation for sale, or intended for the food of man; and in case it appears to the medical officer of health, or the inspector to be diseased, or unsound, or unwholesome, or unfit for the food of man, it shall be lawful for him to seize the same, and for a Justice to order it to be destroyed. In this regulation there is no particular reference to the kind of food which is unwholesome, or to the circumstances which render it so, and, therefore, much is left to the discretion of the officer who examines it. In the City of London the practice is to condemn the flesh of animals infected with certain parasites, as measles, flukes, &c.; and of animals suffering from fever or acute inflammatory affections, as rinderpest, pleuro-pneumonia, and the fever of parturition, and of animals emaciated by lingering disease, and those which have died from accident or from natural causes, as well as all meat tainted with physic, or in a high state of putrefaction. A little practice is required to distinguish meat of this description, but, generally, it may be said, that good meat has the following characters:—

1st. It is neither of a pale pink colour nor of a deep purple tint, for the former is a sign of disease, and the latter indicates that the animal has not been slaughtered, but has died with the blood in it, or has suffered from acute fever.

2nd. It has a marbled appearance from the ramifications of little veins of fat among the muscles.

3rd. It should be firm and elastic to the touch, and should scarcely moisten the fingers—bad meat being wet, and sodden, and flabby, with the fat looking like jelly or wet parchment.

4th. It should have little or no odour, and the odour should not be disagreeable, for diseased meat has a sickly cadaverous smell, and sometimes a smell of physic. This is very discoverable when the meat is chopped up and drenched with warm water.

5th. It should not shrink or waste much in cooking.

6th. It should not run to water or become very wet on standing for a day or so, but should, on the contrary, dry upon the surface.

7th. When dried at a temperature of 212° or thereabout, it should not lose more than from 70 to 74 per cent. of its weight, whereas bad meat will often lose as much as 80 per cent.

Other properties of a more refined character will also serve for the recognition of bad meat, as that the juice of the flesh is alkaline or neutral to test paper, instead of being distinctly acid, and the muscular fibre when examined under the microscope is found to be sodden, and ill-defined.

The signs of parasitic diseases are not always observable without careful examination. In the case of the fluke in the livers of sheep, and of measles in pork, and of hydatids in the brain or liver, the nature of the disease is at once discoverable, but it is not so with the smaller measles or cysticerci of beef and veal, and it is still less so with the trichina of pork—the microscope being required to reveal their presence.

And here, perhaps, we may ask, what are the effects of diseased or putrid meat on the human system? The question is undoubtedly very difficult to answer, for while, on the one hand, we have abundant evidence that such meat

may frequently be eaten with impunity, so on the other we have many remarkable instances of injury occasioned by it. In Scotland there is a disease called *braxy*, which attacks the sheep and lambs in spring and early summer. It is the cause of at least half the deaths in the flock during the year. The disease kills the animals very quickly by causing stagnation of the blood in the most important vital organs; and as the carcass is the perquisite of the herdsman, he almost invariably eats it—taking the precaution to remove the offal, and to cut away the darker portions of the flesh where the blood has stagnated. He also salts it before he uses it; and if questioned on the subject he will tell you that the meat is not unwholesome. Every now and then, however, when perhaps the diseased parts have not been entirely removed, or when the salting has not been sufficiently prolonged, or the cooking has not been thoroughly effected, the most serious consequences result from it, insomuch that many medical practitioners who are acquainted with the habits of the Scotch shepherds in this respect, and have seen the mischief occasioned by the meat, declare that braxy mutton is a highly dangerous food for man. Again, it is a common practice with farm-labourers to eat the flesh of sheep affected with staggers, which is a parasitic disease of the brain; and even of animals dying from acute inflammatory diseases. There is a story told on the authority of Dr. Brücke, the Professor of Physiology in Vienna, that some years ago, when the *steppe-murrain* was prevalent in Bohemia, and the infected animals were killed and buried by order of the Government, the poor people dug up the carcasses of the dead bullocks, and cooked them, and ate them, without injury. In this country also, during the prevalence of *rinderpest* in 1863, enormous quantities of meat from the diseased animals were sent to market, and sold and eaten. The same has been the case with the carcasses of animals suffering acute *pleuro-pneumonia;* and if, as Professor Gamgee says, the practice of making salvage out of diseased animals is so common, that, at least, one-fifth of the meat which is sold in the public markets is diseased, we may well ask, in the words of Mr. Simon, how it is that some sort of pestilence is not bearing witness to the fact? How it is, that cattle having all the foulness of fever in their blood, or having local sores and infiltrations, that yield one of the deadliest of inoculable morbid poisons, or having their flesh thronged with larval parasites, do not when slaughtered and eaten produce a general poisoning? Parent-Du-Chatelet has commented in very forcible language on the apparent immunity from disease even when the most foul and loathsome of animal foods are eaten. But is it not probable that the danger is averted by the operation of cooking? Not that the human stomach has not also a wonderful protective power in its own natural functions; for the deadly poison of the cobra or the rattle-snake may be swallowed with impunity. It is possible, however, that these safeguards may fail us occasionally, and then it is perhaps that the most serious consequences arise. I have often had to investigate cases of mysterious disease which had undoubtedly been caused by unsound meat. One of these, of more than ordinary interest, occurred in the month of November, 1860. The history of it is this: a fore-quarter of cow-beef was purchased in Newgate Market by a sausage-maker who lived at Kingsland, and who immediately converted it into sausage meat. Sixty-six persons were known to have eaten of that meat, and sixty-four of them were attacked with sickness, diarrhœa, and great prostration of vital powers. One of them died; and at the request of the coroner, I made a searching inquiry into the matter, the result of which was that I ascertained that the meat was diseased, and that it, and it alone, had been the cause of all the mischief. Dr. Livingstone tells us that when the flesh of animals affected with pleuro-pneumonia is eaten in South Africa by either natives or Europeans it invariably produces malignant carbuncle. He says, indeed, that the effects of the poison were often experienced by the missionaries who had eaten the meat, even when the presence of the disease was scarcely perceptible; and in many cases when the Backwains persisted in devouring the flesh of such diseased animals, death was the consequence. The virus, he says, is neither destroyed by boiling nor by roasting, and of this fact he had innumerable instances. Now, it is a remarkable circumstance that ever since the importation of this disease (pleuro-pneumonia) into England from Holland in 1842, the annual number of deaths from carbuncle, phlegmon, and boils, has been gradually increasing. In the five years preceding that time the mortality in England from carbuncle was scarcely one in 10,000 of the deaths: from 1842 to 1846 there is no record of the disease; but in the next five years, from 1846 to 1851, the mortality rose to 2·6 per 10,000 of the deaths; and in the next five years it amounted to 6·2 per 10,000; and in the succeeding five years to 5·4. In the case of phlegmons, the increase in the mortality is still more remarkable, for it rose from an average of 2·5 per 10,000 of the deaths in the five years preceding the importation of the disease, to 81 per 10,000 in the ten years from 1847 to 1856. The Registrar-General of Scotland has directed public attention to this fact, saying that deaths from carbuncle are on the increase, and that the mortality from it has been getting larger and larger ever since the lung disease of cattle was imported into Scotland. This accords with the experience of medical practice; but as it is very difficult to trace the immediate connection of bad food with subsequent disease, there being so many circumstances to weaken the connection, it is not surprising that differences of opinion should exist as to the morbific effects of unsound meat: nothing, in short, but an experimental inquiry into the subject, as has already been done in Germany in the case of parasitic diseases, will bring the question to rest; and I see no reason why such an investigation should not be made on the persons of those who send diseased meat to the public market for sale; for, as the common defence of their conduct is, that the meat is good for food, they cannot surely object to the penalty of being made to eat it. Here, for example, is a specimen of pork covered with pustules of small-pox; it was seized by one of the city officers on the road to a notorious sausage-maker, and it may, notwithstanding its disgusting appearance, be good and wholesome food; then why not put the question to the proof by making the vendor of it eat it? In the year 1862, when small-pox was prevalent among the sheep in several parts of England it was a common practice to send the carcasses of the diseased animals to the London markets for sale as human food. Later still, in 1863, there was an epidemic of what seemed to be scarlet-fever among the pigs of this metropolis, and their carcasses, with all the bright crimson look of the disease, were invariably sent to market for sale as food. Since then the London pigs have been the subjects of a virulent spotted fever, of the nature of typhus, and these also have been killed in the last stage of the disease, and sold for food. Abundant illustrations of this kind are constantly coming under my notice; and I feel that the question of the fitness of such meat for food is in such an unsettled state that my action in the matter is often very uncertain, and I should like to have the question experimentally determined; for, as it now stands, we are either condemning large quantities of meat which may be eaten with safety, and are, therefore, confiscating property, and lessening the supply of food, or we are permitting unwholesome meat to pass almost unchallenged in the public markets.

As regards the injurious quality of meat infected with parasitic disease there can, however, be no question; and, perhaps, of all such infections, the most terrible is the *trichina* of pork. Fortunately, it is a rare affection in this country, although it is often common in Germany. The pork infected with the worm is generally darker than usual, on account of the irritating or inflammatory action of the creature lodged in the muscles; and when the parasite is encysted the meat presents a speckled appearance—the minute white cysts containing the worm being just visible to the naked eye. Here are specimens of it in

both its cysted and non-encysted conditions; and this diagram represents the appearance of the worm when it is examined under the microscope. It is, as you see, a minute thread-like worm, of about the thirtieth of an inch in length, coiled up in a spiral form; hence its name, *trichina spiralis*. It is generally found in the human subject in an encysted state, when it has passed beyond its dangerous condition, and has become harmless. In most cases, when thus discovered, there is no record of its action, and, therefore, it was once thought to be an innocent visitor; but we now know that while it was free—that is before nature had barricaded it up in the little cyst, its presence was the cause of frightful disorder—killing about 50 per cent of its victims in terrible agony. In Germany, there have been frequent outbreaks of the disease which, for a time, baffled the skill of the most experienced physicians: in fact, we hardly know how long or how often the disease has attacked the pork-feeding population of Europe, for its actual nature was unknown until the year 1860, when Dr. Zencker, of Dresden, discovered the pathology of the disease. Since then there have been several visitations of it, as at Plauen, in Saxony, in 1862; at Hettstadt, near Eisleben, in 1863; and at Hedersleben, near Magdeburg, in Prussian Saxony, in 1866. In all these cases, the same symptoms, or nearly the same, were observed; there was sometimes immediate disturbance of the digestive functions, but more commonly a day or two elapsed before any particular symptom was noticed, and then there was a feeling of lassitude, with a loss of appetite, and pains in the head and back. Then followed a serious disturbance of the alimentary canal, with vomiting and diarrhœa. This lasted for a day or two; and by the end of a week after the worm had been eaten, fever had set in, which became more and more severe, and by that time the young worms which had been hatched in the body, had migrated to the distant muscles, causing the most excruciating pains, so that the patient, fearing to move his inflamed muscles, would lie motionless upon his back; and if he did not die in this state of the disorder nature came to the rescue, and imprisoned the creature by surrounding it with a fibrinous cyst, where it lives for years, being ready at any moment to acquire activity when it is swallowed and released from its cell. Indeed, the way in which it becomes dangerous is this—flesh infected with the parasite is eaten; and the cyst being quickly dissolved by the gastric juice, the creature is set free. Finding itself in the midst of nourishing food, it rapidly grows, so that in two or three days it is three or four times its original size, and may be easily seen like a bit of fine thread with the naked eye. The worms are of different sexes, and they rapidly come to maturity—each female giving birth to from 300 to 500 minute thread-like worms, which immediately set out upon their travels, piercing the walls of the intestines and migrating to distant parts of the body, where they produce the terrible mischief which I have described. Although the pig is the animal which is most commonly infested by it, yet it has been found in the muscles of dogs, foxes, badgers, sheep, moles, hedgehogs, rats, mice, frogs, and most carnivorous birds, all of which must have been subjects of the disease, but none appear to suffer from it like man—even children are less affected by it, for they seem to sleep it away. Fortunately, there is an easy method of discovering its presence in animals, for the most certain seat of the creature is in the muscles of the eye; we have, therefore, only to examine these muscles with the microscope to declare whether the meat is infected or not; and, at the present time, the sausage-makers of Germany have the pork examined in this manner before it is used for food.

Other parasitic creatures, as measles in pork, and the smaller *cysticerci* of beef and veal, are found as little sacs or bladders diffused through the lean of the meat—the *cysticercus* or *measle* of pork being easily seen, for it is as large as a hemp seed—here are specimens of it in a fresh condition, which were seized in the city markets to-day; but the cysticercus of other animals is much smaller, and requires careful exploration to discover it. In both cases the sac contains a little creature with a sort of tuberculated head, crowned with a coronet of hooks, and having a bladder-like tail attached to it. Soon after it is swallowed, the enclosing sac is dissolved by the gastric juice, and the creature being liberated passes into the intestines and there fixes itself by its little hooks, and quickly grows, joint after joint, into a tape-worm. In the case of the cysticercus of pork it forms the variety of tape-worm called *tenia solium*, and in that of beef and veal it produces the *tenia-mediocanellata*. The latter is the most common variety of it in the human intestines, and it is frequently seen where raw, or nearly raw, meat is made use of, as in Abyssinia and in Russia, where children are allowed to suck a piece of raw beef, on the supposition that it has a strengthening property. Each segment of the worm is an independent creature, containing myriads of ova, and when passed by the bowels, it gets with the manure upon the land and is eaten by pigs, oxen, and goats: the ova are then hatched in the stomach; and they pass, as in the case of the trichinia, through the walls of the intestine, and migrate to the muscular tissues of the body, where they become encysted, and form the little sacs or measles which remain dormant for years, though they are ever ready to become tape-worms directly they are eaten. In this manner the creature is perpetuated, first as a tape-worm with joints in the intestines of one animal, and then as a measle or larva in the muscle of another, and then again as a tape-worm. By a like process the *tenia echinococcus*, or little tape-worm of the dog, becomes the *hydatid* in man and other animals. In Iceland the dogs are very liable to this infection, and the cattle and sheep, as well as man, suffer from the hydatid of it. The subject has been well investigated by Dr. Leared, who has shown that the practice of giving the diseased offal of the slaughtered animals to dogs, causes tape-worm, and the dogs drop the segments of the worm, filled with ova, upon the pastures and into running water. By this means they enter the bodies of cattle and sheep, and even of man, and then, as in the last case, the ova quickly become developed, and the young hydatid or larval tape-worm, piercing the walls of the alimentary canal, migrates to distant parts, and finding a suitable nidus for its growth, it slowly becomes a large bladder-like *hydatid*. In the case of the sheep it often selects the brain for its habitat, and produces the disease called *staggers*; in oxen it grows in the peritoneal cavity, and in man it haunts the liver, occasioning frightful disturbance of the system, and causing one-sixth of the total mortality of that country. Here are specimens of the disease from the human subject.

Again, there is another class of parasites called *trematoda* or *flukes*, which infest the livers and intestines of men and herbivorous animals. The most common of them is the *distoma hepaticum* or *liver-fluke* of the sheep. In wet seasons the animal is so constantly infested with them, and suffers so much emaciation from them, that the disease is called the rot. You have before you infected livers which were seized in our public markets this very day, and there is no difficulty in obtaining specimens of them at almost any time. A few years ago (in 1863), when Professor Brown was lecturing on the liability of animals to disease from their present mode of feeding them, he said that once, when he wanted some animals for dissection and applied for them to a large butcher, he received back five or six animals which, though in a bad state of rot, were dressed for the market; and he was told by a certain individual not far from London, that within the space of six months he had killed no less than 750 of such animals, in a state of extreme disease, and he believed they were all sent to market and sold for food. What becomes, he says, of the hundreds and thousands of rotten sheep which we see in the fields? To bury them would require whole catacombs; the real catacombs are the intestinal canals of the human body. The way in which the disease is produced in sheep is curious. Ova are passed from the gall-bladder of an infected animal into the intestines, and so upon the land: finding a moist situation they are soon

hatched into cyliated embryos, which swim about and become developed into cylindrical sacs or minute hydatids; these attach themselves to some mullusc, as a small snail. In wet weather the infected snails crawl upon the grass, and are eaten by the sheep, and then the hydatid speedily changes its condition and becomes a fluke. When it is found in the body of man it has perhaps been drank with water or eaten with some aquatic plant, as water-cress, &c.

Our safety against these intruders is to cook the meat thoroughly.

(To be continued).

THE RATIONAL TREATMENT OF CONSUMPTION.

By JOHN MULVANY, M.D., L.R.C.S.Ed., Etc.,
ASSISTANT-SURGEON, R.N.

(Continued from page 396.)

BABIES.

With regard to births in Ontario, this year, they occurred in batches. Along the shore of Lake Erie, during the latter end of July and the whole of August, nightly platoons of muling babies were ushered into the world. In the West Indies, the fecundity of the natives is remarkable; in some parts of Jamaica where I have been, a family of ten or twelve is considered moderate. A Hebrew merchant, to whom I made some observations about the size of his family (he had ten), assured me that 16 or 18 was an ordinary number of children to have. The fecundity of a Santa Martana, who was the subject of a septuple birth, is perpetuated in Santa Marta, by the street, in which the remarkable event occurred, being designated—

"La calle de los siete minos."
"The street of the seven children."

It is, to my mind, impossible to witness the advent of so many Pickanninies in the West Indies and Central America, and the remarkable coincidence of six or seven, or twelve women bringing forth at the same time, in two small villages a few miles apart in Ontario, without connecting the occurrence with some atmospheric influences. In Jamaica, New Columbia, &c., the weather is, for the most part, hot and dry, the atmospheric electricity positive, of strong tension, and accompanied with ozone; in Canada a continuance of such weather is rarely found. No doubt the heat of July and August equals that of the tropics, but a high temperature is familiar to the creoles and the acclimatised, but is not so to the Canadians, and consequently the enervation which it induces weakens, or almost neutralises, the otherwise tonic vivifying procreative producing effects of the positively electrified atmosphere of July and August. In October and November, however, the heat of the Indian summer, less intense than that of July, but relatively as high as that of Jamaica is to the natives, by its stimulating effects assimilates the climatic conditions of Canada to those of the tropics, and hence the eruption of babies in July and August this year, 1867. I dare say a close observation of the weather in England would establish the same relationship—similar cause, like effect. In Jamaica, and other West Indian islands, where a peculiar facility is offered to this kind of observation, I do not hesitate to say that the heat, electric tension, and ozone, stimulate the procreative organs to such an extent that the animal passions predominate over the maternal feelings—hence the large number of births and high infant mortality. This, more especially, applies to the coloured population. That a similar influence is felt by the whites is less easy of recognition, because their natural impulses are restrained by education, moral culture, society, &c., bridles insufficient to restrain the people of colour. That these are frequently thrown aside, even by the whites, cannot be denied. Midway between Lucie and Montego Bay, the traveller will observe the ruins of a house which, at one time, must have been of palatial magnificence, the property of an heiress, peerless as Juno, lovely as Venus, charming as Circe, but more cruel than Medea, whose life of debauchery, duly chronicled by a biographer on the estate, was terrible in its depravity, and the more hideous when her beauty and loveliness are taken into consideration, with her cruel, murderous, and licentious disposition. She was put to death by her slaves, the sharers of her revels by night, the recipients of her lash by day.

But though a ship of war presents unusually favourable opportunities for ascertaining the electrical condition of the atmosphere, it is not all times possible to do so, and is never, under any circumstances, so easily ascertained as its ozonic condition, and as its state of ozonization is intimately connected with its electric condition, and this with those changes whereby the thermometer and barometer are affected; and, moreover, as actual and repeated observations had enabled me to connect the exaggeration of the phthisical symptoms which occurred when the ozonometer remained unaffected with the absence of ozone, as well as the improvement which took place when it was detectable with its presence, I have been led to look upon it as an agent essentially necessary to the proper oxidation of the blood. The well-known advantages of a sea-side residence for consumptive patients lends confirmation to this view, since, in all probability, its salubrious effects are in a great measure owing to the ozone which, according to Admiral Fitzroy, is always present in a sea-side atmosphere, a statement with which my own observations on the coasts of Mexico, Cuba, and Jamaica, are in accordance. The aggravation of the symptoms occasioned by its absence is, therefore, I presume, owing to a diminished elimination of carbonic acid, which adds its stimulating action on the heart to those already existing. Significant of the inadequate supply of oxygen in the blood in phthisis is the immense advantage derivable from a residence in an elevated locality, such as on the sides of the Andes, on the Anahuac heights in Mexico, or the hills in Jamaica, if the observations of Jourdanet be correct. At an altitude of 2000 mètres, he says, "a man, whilst taking in the usual amount of oxygen, gives out a larger amount of carbonic acid than he would at the ordinary level." Dr. Prout also says—"carbonic acid is given out in greater quantity when the barometer is low, a condition which obtains in elevated localities, the air there is always pure, bracing, and free from moisture." Pregnancy is considered antagonistic to phthisis, and this is usually advanced in favour of the hyper-oxidation theory—the blood, they say, is more venous in consequence of the diminished capacity of the chest, and the excess of carbonaceous elements resulting therefrom will obviate the vicious effects of excessive oxidation. But the opposite must really be the case, since, according to Andral and Gavarret, the quantity of carbonic acid exhaled during pregnancy is remarkably increased. The blood must, therefore, be rather in a state of hyper than sub-oxidation.

After parturition the disease is said to be especially prevalent, the reason which I would suggest for this is apparent to all, and distinctly corroborative of the theory I advance. During the period of lactation, the baby sleeps by night in its mother's arms, cuddled closely up to her fond bosom, the loving maternal head bent gently towards it. The child's breath will, therefore, instead of passing off directly into the atmosphere, be thrown against the mother's breast, and reflected upwards, to be drawn into her lungs during inspiration, the imperfect decarbonization which will result will, aided by anxiety, broken rest, fatigue, and exhaustion, be amply sufficient to institute tuberculosis. I may instance the benefits derived from the use of chloras potassæ as another fact corroborative of the defective oxidation theory. This medicine was at one time vaunted as a specific in phthisis, and, as such, indiscriminately used, abused, neglected, and depreciated. Its action is not specific, but purely chemical, and consequently

intelligible, its beneficial effects depending on its furnishing a large proportion of oxygen.

I will now pass on to the consideration of those data on which the hyperoxidation theory most immediately rests, viz.—the increased temperature, emaciation, and the benefits derived from fats, oils, and alcohol. First as to the

ELEVATED TEMPERATURE.

It is natural to suppose that as animal heat is in a great measure produced by combustion, an increase of heat denotes increased combustion, but this implies an increased assumption of oxygen, for which a corresponding augmentation in the quantity of air inhaled in a given time is absolutely essential. The rapidity of the respiratory act in phthisis would warrant this view, were the integrity of the lungs preserved. But we must bear in mind that this is not so. A man in health, whose vital capacity is 225 cub. inches, breathing 16 times per minute, and changing 22½ cub. inches of air in each respiration, "the mean between the minimum and maximum given by Mr. Coathupe, 20—25, will change 360 cub. inches per minute, but in phthisis the vital capacity is diminished 93 cub. inches. Therefore, if we say the vital capacity in health is to that of phthisis as the breathing air of health is to that of phthisis, *i.e.*—

$$225 : 132 : : 22\tfrac{1}{2} : 13\tfrac{1}{2}$$

we find the breathing air reduced to 13½ cub. inches, and the phthisical patient will, accordingly, have to breathe 27 per minute to inhale as much air as a man in health. But this is supposing that all the lung which remains sound is inflated by each inhalation, but this cannot be so except by a forced inspiration, because there are generally pleural adhesions, pleuritis, pneumonitis, or neuralgic pains, to render the breathing shallow, so that, in fact, 36 or 40 respirations would be requisite in phthisis to maintain the temperature of the body at the ordinary height. The increased heat, therefore, is no more owing to increased combustion in phthisis than is the elevation of temperature observed after death from yellow fever to increased activity! The combustion theory of the heat produced by inflammation has received its death blow from Dr. Beale, in his admirable lectures published in the *Medical Times and Gazette*. He says, page 594, June 10, 1865:—"Now, so far from inflammation depending on increased oxidation, it would seem that the oxidising process is greatly diminished in intensity or altogether stopped. I think a careful consideration of the facts render it more probable that the rise in temperature is due to the increased multiplication and germination of the masses of germinal matter, than to oxidation. The process of germination generally seems to be intimately associated with the setting free of heat, but it is very doubtful if it depends upon oxidation, since it is proved by observation that the conditions favourable to free oxidation are not present." Eschewing, therefore, the theory of increased combustion, we find an explanation of the increased heat of the body in phthisis, in the germination and multiplication of the tubercle cells, in the retention of heat produced by the impeded action of the sweat glands, the cooling effects of evaporation from the surface of the body being thereby lost in the more rapid circulation of the blood through narrowed channels, occasioning increased friction, and in the greater activity of the sympathetic and vagus nerves. These two latter seem to have a very powerful influence in keeping up the heat of the body, for I found that the temperature fell 4°·5 in seven days on administering a medicine which calmed the nervous excitation, tranquilised the circulation, and promoted diaphoresis.

EMACIATION, FATS, OILS.

The removal of fats which takes place in phthisis, and the acknowledged benefit which follows their internal use, seem to militate strongly against the defective oxidation theory, since their use in the animal economy seems to be to furnish materials for combustion, containing as they do carbon and hydrogen in large proportions; were there really a condition of hyperoxidation in the system, the increase of fuel should augment the conflagration, but the administration of fats and oils does not raise the temperature in phthisis. Moreover, it must be borne in mind that the use of fat is not merely to support combustion, that it is one of the essential constituents of nerve tissue, that it is a normal element of the blood, and is always present in healthy bile. Is it, therefore, a matter of surprise, that the small supply of fats thrown into the blood by the lacteals in the earlier stages of phthisis should be appropriated to the renewal of the cerebrine, phosphorised fat, seroline cholesterine, &c., lost in the wear and tear of the tissues? rather than be applied to the purposes of combustion, for which that stored up in the omentum, or hid away amongst the muscles, seems to be reserved. Late Alpine experimenters show that muscular heat and muscular force are not altogether due to direct oxidation of the muscular tissue, but that the hydrocarbons are made contribute to it. Emaciation would therefore seem to result rather from diminished supply than excessive waste; for when the supply is increased, that is when the removal of excessive acidity enables the patient to digest fats, he gains rapidly in weight. On the other hand, when the elements of imperfect oxidation increase to such an extent, that they are thrown on the liver and kidneys for elimination, the elements of fat are synthetically combined, and a fatty liver results. We may therefore assume that fats and oils are useful in phthisis, because they furnish materials for repair to the nerves and blood, &c., administer to muscular force, and, consequently, become tonics of the first order.

ALCOHOL.

Neither do the beneficial effects of alcohol in phthisis warrant us in assuming that hyperoxidation exists. Since the experiments of L'Allemand and Perrin have shown that it does not belong to the category of respiratory foods, as stated by Liebig and others, that it does not undergo progressive oxidation, that it does not produce change of colour when mixed with blood in equal proportions at 55° centgr., that the elimination of carbonic acid instead of being increased is rather diminished by its use, that it exhibits a peculiar electivity for nerve matter, and that it is rapidly thrown out of the body by the lungs, skin, and kidneys; any benefit derivable from it must therefore be due to its action on the nervous system. This action has been much discussed, lauded as tonic, decried as toxic, recommended as narcotic, or employed as stimulant, its administration has been for the most part empirical rather than scientific. The great preference it exhibits for nerve tissue, and its remarkable affinity for water, make it highly probable that its effects are owing to a modification of nerve power produced by an abstraction of a portion of the water which enters largely into the composition of nerve substance. The brain and spinal cord have long been compared to a galvanic battery, and the nerve influence to the electric fluid. Its generation, resulting from the vital and chemical actions, whereby the change of nerve tissue is effected, is liable to be modified by causes operating through the blood, or through the brain, by the stimulus of the will setting up increased action, or through causes pertaining to the atmosphere. Alcohol acts through the blood: passing *vid* the stomach and portal vein into the circulation, it is taken up par preference by the brain-matter, from which it abstracts a portion of its water; condensation and a liberation of heat ensue—phenomena so closely associated with electrical development that we may presume, that from their action on the great battery—the brain, electricity results, the amount developed being in proportion to the action produced; when a small dose of alcohol is taken, the electricity produced, being in direct ratio to the heat generated in the brain-cells, will be small. Under such circumstances its action on the brain and general system, closely resembles, *cæteris paribus*, that of a galvano-electric current on the muscles of the forearms: the feeling of bienveillance, the sensation of comfort in

the region of the solar plexus, the flow of genial ideas and more facile movements of the tongue, being the analogue of the pleasurable sensations which run tickling through the median nerves, and the slight muscular movements of the flexors of the forearms. When the action is more energetic, a more copious evolution of electricity takes place; the intellectual faculties are more stimulated, the muscular strength is increased, and the circulation accelerated, at least, primarily so. A still greater evolution, stimulating more energetically the cineritious substance, causes the ideas to be engendered with such velocity, that the partially overpowered conducting and expressing media are unable to meet the increased demand on them, and the ideas tumbling over one another in the mind, produce the partial incoherency characteristic of that stage of inebriety elegantly yclept "tight," "screwed," "entre deux vins embriagado," &c. In this stage those portions of the hemispheres which rule the dominant phases of the mind are most stimulated, and ideas are evolved in accordance with the characteristic traits of the individual. Thus, one man will sing, another quarrel, a third grow lachrymose, &c. A still more violent action, such as results from a very large dose of alcohol, or from repeated bumpers, liberates such an amount of electricity, that the normal functions of the brain are overpowered and dead drunkenness results, just as a single, sudden, and violent aërial vibration, or a succession of less powerful ones will, by producing an inordinately strong impression on the auditory nerve, suspend its functions, overpower it, and produce deafness. In a similar manner, too strong an impression on the filaments of the olfactory will render it unable to communicate to the brain the impression of odours, and smell becomes lost. A strong application of the galvanic current to the vagi will stop the heart, or to the phrenic, will suspend the play of the diaphragm. The functions of the brain are similarly removed by too strong a stimulation, whether that be applied through its cineritious substance, as by exciting passions, or through the electricity generated in the brain-cells by alcohol. In the one case the superabundant electricity may find a vent in an hysterical paroxysm, spasms, or convulsions, before it has had time to overpower the cerebral functions. In the other, a timely reduction of the electric action will avert the loss of consciousness witnessed in drunkenness. Cold water copiously drank will accordingly prove the surest restorative to sobriety. When the mental operations are completely overpowered, and volition, which presides over the direction of the nerve-currents, *hors de combat*, a strong impression made on the surface of the body, such as by cold affusion, will, by causing the medulla oblongata to direct a current of nerve-force through motor nerves, give vent in this way to some of the superabundant electricity, relieve the oppressed brain, and restore to sobriety. On the same principle, sousing in cold water offers the most rational and efficacious method of treating insensibility produced by lightning. Further analogy may be traced by observing the similar action of alcohol and electricity in various states of the body. Thus, electricity has been employed successfully to remove spasm. Hutchinson treated tetanus by alcohol with complete success. Certain kinds of neuralgia are amenable to electricity. I have treated the same with the most rapid and satisfactory results by rum-punch. Faradisation of the mammæ of a delicate mother, whose shattered nervous system soon after accouchement is unable to furnish an adequate stimulus for secretion, will rapidly gladden her eyes by the copious lacteal secretion it will occasion. I have seen beer produce the same results equally rapid and gratifying. Its action could not be merely stimulant; were it such we might expect tea, coffee, or ammonia to act equally well: but such is not the case. In the following case the identity of their action is, I think, illustrated:—

N. Fleming, æt. 31, A.B., H.M. gunboat "Britomart," came under my care on October 3rd, for paralysis of the right hand, which came on suddenly from no tangible cause that morning. He denied having been drunk the night before, and was positive in his statement that he did not sleep on it. I treated him with galvano-electricity for a week, with much benefit. He then went to sea in his ship for four days, and as I belonged to another gunboat, the electricity during that time was necessarily omitted. On the evening of the fourth day his ship returned, and he again came under my care. No improvement had taken place; on the contrary, the paralysis was greater than when the electricity was omitted. The sensation was good, but the muscular power, particularly of the extensors, was very weak. He could lift a weight, but it would slip out of his hand unconsciously. His ship was to proceed on a cruize again early the next morning, so I did not re-apply the galvanism, but resolved to try the electrical-producing effects of rum, and ordered him half a-gill four times a-day in water. To my surprise, on seeing him again in three days, his hand had so much improved that he could lift and hold heavy weights, and perform all his duties but rifle-drill, with which a still trivial weakness of the extensors interfered. This totally disappeared in a few days longer.

Again, in the prostration which succeeds acute diseases, such as erysipelas, remittent yellow fevers, or insolation, when the heart beats range between forty and fifty, good food, bark, iron, or ammonia will produce beneficial effects trivial in comparison with good food and a bottle of porter. The fluttering of the heart in women at the climacteric period, and the trembling of the hands succeeding a debauch, depending on an equally enfeebled nerve-power, are similarly amenable to alcohol.

Dr. Caplin cures the cold stage of ague by electric agency, through the medium of a hot-bath. Guyot gave rum or Geneva with like success. Alcohol destroys the coagulability of the blood; so does lightning. The best indication for the administration of alcohol would therefore seem to be an insufficiency of nerve-force. Nervous irritability is not synonymous with a superabundance of nerve-power, but frequently with the opposite condition, as in phthisis. In this disease, therefore, it reinforces the nerves by the generation of supplemental electricity: the pulse as a consequence becomes slower and stronger; the nerves of organic life being strengthened, remove arterial contraction and capillary congestion; the organic cuticular fibres are relieved of their tonic-spastic condition; the heart's action becomes slower; perspiration is promoted, and the body is cooled.

(To be continued.)

Hospital Report.

GUY'S HOSPITAL.

A CASE OF THE HÆMORRHAGIC DIATHESIS.

Under the care of Mr. ARTHUR E. DURHAM.

In our notice of the Guy's Hospital Reports for this year, we promised to abstract now and then a case for this department of our journal. The following case of stone in the bladder, in a patient of the hæmorrhagic diathesis, in which lithotomy was performed, seems to us of great interest, and we accordingly select it as a commencement:—

James Joy, æt. 3½, was admitted into Charity Ward under my care on the 9th April, 1866. He had had symptoms of stone in the bladder for four or five months. He was a fair child, with clear pale complexion, light hair and blue eyes. He had much of that general prettiness of aspect so often observed in children with stone in the bladder. At the period of his admission to the hospital his sufferings were evidently very severe. A roughish stone, apparently of medium size, was readily detected by means of the sound. The mother was told the nature of her child's malady and informed as to the proposed method of cure. She at once expressed a strong conviction that the child, if operated upon, would certainly die; "for,"

she said, "three of his brothers have bled to death from very little wounds—it is in the family." She, however, freely consented to anything being done that should be thought right, inasmuch as she felt sure that the child could not live long as he was, and that while he did survive his life would be prolonged misery, not only to himself but to others. Notwithstanding the unpromising character of the case, it appeared to me right to operate. This conclusion was confirmed by the opinions of my colleagues.

Accordingly, on the 17th April, I performed lateral lithotomy on the straight staff in the usual manner, and extracted a lithic acid calculus about as large as a filbert. The operation was very quickly performed. The stone was caught immediately and withdrawn without the slightest difficulty. There was comparatively little hæmorrhage. So little, indeed, that the remark was made by Mr. Birkett, that I need not have frightened myself about bleeding, for there appeared to be less than usual.

The operation was performed about two P.M. I watched the child until five o'clock. All oozing of blood had then ceased. As far as I could judge no more blood had been lost than in ordinary cases,—less indeed than I have seen in many. The child was pale and rather low, but apparently comfortable. A little wine was given. Soon afterwards slight hæmorrhage recurred. The surface of the body became quite blanched. In spite of the measures taken oozing of blood continued with certain periods of intermission. Every effort was made to stimulate and support the vital powers; but the child sank rapidly, and about 8·30—that is, about six hours after the operation—he died.

A post-mortem examination was made seventeen hours after death by Dr. Moxon.

A slight bruise-like mark was observed over the anterior superior spinous process of the ilium on the right side, also a smaller one on the dorsum of the left foot. There was marked lividity of the forehead, especially above the left eyebrow. This was found to be due to effusion of blood under the occipito-frontalis, and over the temporal fascia. There were two distinct patches, one about the right supra-orbital nerve, and one about the left, the latter being the larger. There was no external bruise of the skin, nor any injury to bone.

The gums were pale, not swollen.

The lungs collapsed very completely, and were anæmic.

The thymus was well developed.

The heart was firmly contracted, and the cavities contained small firm clots.

The blood on microscopic examination showed an excess of white corpuscles.

The intestines contained little or no air, and were soft and pasty to the touch, being anæmic. The mucous membrane of the stomach and intestines appeared white.

The left kidney was normal. The right appeared very small, and lobulated to a marked extent. The surface was slightly granular.

The bladder was firmly contracted. The incision made at the operation appeared theoretically perfect. Lying in it and distending it to a certain extent was a clot of firm consistency. On either side there was a little blood in the areolar tissue, but not more than one or two drachms.

Warm water was injected into the left internal iliac artery. Very considerable pressure was employed before any oozing or escape of fluid from the wound took place.

Family History.—Subsequently to the death of the child, the mother gave the following account of her family history: she said, "As far back as my own grandmother's generation, and from hers downwards, the male children have been subject to great bleeding from slight causes. Three of my own brothers died before they were four years old, from loss of blood. Of my own offspring, three have already died from the same cause. This one makes the fourth." The circumstances giving rise to the hæmorrhage in the first three children were as follows:—

1st. A boy, æt. 13 months, had an abscess over the knee. This was lanced. Hæmorrhage followed, and death occurred in five hours.

2nd. A boy, æt. 7 years (the eldest of the family), bit his tongue one Tuesday evening; it bled constantly until the Sunday morning, when the child died, evidently from loss of blood.

3rd. A boy, æt. 3¼ years, fell down and cut his gums. Death, caused by continued hæmorrhage, occurred in four days.

In each of these cases various means were employed for the arrest of the hæmorrhage, but without avail.

With respect to the little boy whose case forms the subject of this paper, the mother stated that about twelve months before his admission to the hospital he had bled profusely from the gums. This she attributed to teething. Some months later, she noticed a small lump on the child's back, which came suddenly and disappeared gradually, being coloured like a bruise as it dispersed. At other times, also, she had seen coloured patches about the child's skin in various parts of the body.

The mother further stated that a similar tendency to bleed from slight causes existed in the male children of her sister; but hitherto none of them had died. The female members of both families appeared to be quite free from any such tendency. This was also the case, so far as she knew, in previous generations.

Literature.

PRINCIPLES OF CHEMISTRY.[1]

ORIGINAL and learned is the only verdict that any dispassionate reader can pass upon this work. The object of the author seems to have been mainly to introduce to the French chemical student the theory, or rather we may say, theories that have been built up upon the discoveries of Cannizzaro, Gerhardt, Hofmann, and Williamson. Strange to say, according to M. Naquet, these theories were not taught in that country. It seems that in spite of the labours of M. M. Gerhardt and Wurtz existing in France, a system of chemistry quite foreign to the ideas of the old philosophers, but compatible with the works of those chemists, was slowly making its way through the whole of Europe, except in the soil that gave it birth.

"This book," says the author, "marks a period—it is chemistry making a halt in the midst of its conquests, and contemplating at the same time the road already traversed, and the goal to be attained."

M. Naquet also states that his professorship (*professeure agrégé a la faculte de medecine de Paris*) authorizes him in thinking it will become a *classical* text-book for the student of medicine. We presume that M. Naquet means by inserting the adjective prefix, that it is the work for the dilettante medical man, or the pure physiologist. If this is not his meaning, we cannot help thinking that the works deal too much with the higher walks of the science, and is hardly practical enough for a general adoption as a text-book. It is the author's opinion that the student neglects too much the knowledge of the laws that regulate the facts, and gives useless attention to the facts themselves. We are, however, of opinion that M. Naquet falls into the opposite extreme. As chemistry now stands it is purely a practical science, to be studied by facts, and through facts. Intense devotion to the theories of the science is the vocation of a pure chemical student, not the particular calling of a student working at a collateral science.

The style in which this work is written is bold, and at first sight might seem rather egotistical; it is, however, simply the self-confidence of a man who is really writing upon a subject that he understands, and it is quite refreshing to take up a work which is not written in the old stereotyped style of our English manuals.

After reviewing the atomicity of radicals (p. 32), and explaining M. Hofmann's designation of "quantivalence," he dwells at some length upon M. Delavaud's theory, that radicals of uneven atomicity can never exist in the free state without becoming doubled. He points out, however, that there are the molecules NO_2 and NO (hyponitrous acid, and binoxide of nitrogen), which would be exceptions to M. Delavaud's theory,

1 Principles of Chemistry. Founded on Modern Theories. By Mons. A. Naquet. Translated from the Second Edition by W. Cortis. London: H. Renshaw. 1868.

and goes on further to state that such theories go beyond the hypotheses permitted in experimental sciences. They are metaphysical—"In the experimental sciences theories ought only to be the generalization of facts which they ought never to exceed. M. Delavaud's theory exceeds facts, since it supposes subatoms, whose existence is not demonstrated. If such theories were allowed, a thousand might be propounded which would be as justifiable as that of M. Delavaud, and which would reciprocally oppose each other. Instead of confining ourselves within the limits of experiments, we should arrive at empty reasoning like the metaphysicians of the middle ages." We agree with M. Naquet here, but think that his remarks hardly tally with those already criticised, and also appertain to many of the other things belonging to modern chemistry, *e.g.*, such as would be entailed by the acceptance of the graphic notation (M. Kékulé's) which he is now attempting to establish. An excellent specimen of M. Naquet's powers of compilation and arrangement will be found in the section on solubility (page 62).

Under the head of oxygen M. Naquet reviews the present state of our knowledge of ozone as follows:—

"When oxygen is transformed into ozone, a contraction is observed in the mass, but when the ozone which the gas contains is absorbed no contraction is produced.

"Two theories may account for this phenomenon. The first consists in admitting that the ozone is in such a state of condensation that its disappearance by the side of a great excess of oxygen gives no appreciable diminution of volume. By the second we suppose a molecule of ordinary oxygen $\left.\begin{matrix}O\\O\end{matrix}\right\}$ to be united in the ozone to an atom of allotropic oxygen, thus—$\left.\begin{matrix}O\\O\end{matrix}\right\}$ allotropic or negative oxygen, with contraction to $\frac{1}{3}$. The ozone will then contain a volume of ordinary oxygen equal to its own. If we cause reaction to take place between ozone and a body which is oxidized by it, there remains ordinary oxygen which occupies exactly the volume which the ozone occupied; there is no contraction.

"M. Schœnbein's antozone (for he admits another allotropic state of oxygen, which he calls antozone), would be $\left.\begin{matrix}O\\O\end{matrix}\right\}$ positively electrified oxygen."

Both the metalloides and metals in this work are classed according to their atomicity, and these atomic weights are deduced in every case from Dulong and Petit's law on specific heat. M. Naquet was not aware of M. Roscoe's recent researches upon vanadium, and therefore he places that substance amongst the third class, or triatomic metals, viz., gold, vanadium, and thallium. It is, however, from the researches quoted above, evident that this element must be placed in the group of pentatomic metalloids, which included the elements nitrogen, phosphor, arsenic, antimony, &c.

The second inorganic part winds up with an appendix, in which Prout's hypothesis of the atomic weight of all simple bodies being multiples of the atomic weight of hydrogen is considered. He opens with the remark that, for a long time philosophers have been disposed to admit that all matter is one and the same, and that the numerous substances we see are only different manifestations of it. Manifestations, the diversity of which depend upon the degree of its condensation. This idea, well explaining the fact that gravity acts equally on all bodies, and answering moreover to the idea we have rightly or wrongly of the simplicity of the great laws of nature, is introduced into science. A very short time since an English chemist, Mr. Graham, admitted in speculations on the constitution of matter, that chemical atoms are formed by an agglomeration of particles smaller than themselves, and identical, to which he gave the name of ultimates. These ultimates are animated by vibratory movements, the variable length of which in different bodies causes the differences observed between these. Previously Prout wished to give to this theory an experimental proof. He asserted that the atomic weight of all simple bodies are exact multiples of the atomic weight of hydrogen. M. Dumas, in 1859, modified this by saying that the atomic weight of all bodies are the exact multiples of that of an unknown body, which would have an atomic weight four times smaller than hydrogen.

M. Stas, however, has proved two things which materially affect the question. He proves the justness of Wenzel's statement, viz., the invariability of the proportions in weights of the elements forming chemical combination; but, at the same time, conclusively proves that the atomic weights of the elements are not simple multiples of hydrogen.

In the organic part, we may mention, as points of interest to the chemist, the author's remarks upon the classification of organic chemistry, and the tables of homologous bodies, exhibiting Gerhardt's, Bertholet's, Cahour's, and Pelouzes' nomenclature. The account of non-volatile alkaloids will be found rather more full than ordinarily given, and a part is specially devoted to the action of reagents on organic compounds generally.

In the introduction to the organic part, the author says, that some years ago it was believed that life was necessary to the formation of the proximate principles of living bodies. Hence arose the division of chemistry into organic and inorganic—one of the principles of the urine—urea—having been synthetically or artificially produced, the barrier which separated the two chemistrys was overcome, and it became possible to hope that some day all the organic products might be prepared synthetically. This hope has to a great extent been realized by the labours of M. M. Kolbe, Berthelot, Wurtz, Kékulé, Perkins, Simpson, and others, at the present day, therefore there are no longer two chemistrys. *Organic* bodies must not however be confounded with *organized* bodies. The study of organized bodies does not belong to the domain of chemistry, but rather to biology. If at this point biology approaches to chemistry it is entirely to borrow light from it, as chemistry itself borrows from physics, and physics from mathematics, without each ceasing to be a distinct science. It is solely because this distinction has not been universally perceived, that in almost every treatise upon chemistry, articles are devoted to the blood, muscles, etc., which ought only to be contained in works on physiology. So much for M. Naquet. In conclusion, we must say a few words as regards the translator's part.

We have not had the pleasure of meeting M. Cortis before as an author. If it is his first essay it is certainly a most creditable performance, and one which lays the English chemical world under some considerable obligation. He is one of those gentlemen who could discriminate as regards the labour to be performed, and also possessed the ability to do it efficiently. He states that one of the inducements to him to translate the work was to introduce Kékulé's diagrams. Although we do not admire this system much, it will no doubt add interest to the book, as no other English work gives an account of this method. It bears some resemblance to W. Crum Brown's system of graphic notation.

There are a few typographical errors, but very few for so large a work, and the printing and general "get up" of the book are excellent. It would, however, have been better if the diagrams had been re-engraved with English words instead of French.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 13, 1868.

THE SCOTTISH UNIVERSITIES AND THEIR MEDICAL GRADUATES.

WE have followed so regularly every phase of the questions that have arisen since it was proposed to grant representation to the Scottish Universities in Parliament, that our columns will be expected to contain a summary of the latest movement. Accordingly, we proceed to state that the memorandum which it was resolved to prepare at the late General Session of the St. Andrews Graduates'

Association, has already been drawn up, and exhibits, as clearly as possible, the claims of the Doctors of Medicine to a seat in the General Council of their University. It remarks that, as a rule, Honorary Degrees do not give a voice in the government of the University conferring them, nor a vote for a Member of Parliament when the University returns one. Whether this should be so we do not pretend here to decide, since it does not affect the question at issue. It might, however, be considered a good thing for no restriction to be made, as such a relaxation would tend to limit the issue of Honorary Degrees, and no one would grudge the slight additional privilege in the few cases in which they were conferred as a recognition of high attainments.

We are concerned with ordinary degrees. These (if Masters' of Arts or superior) entitle the holders to be Members of the General Council, or Convocation, or Congregation, or Senate of the University, and to vote for the Member of Parliament. In some instances, Bachelors of the several faculties enjoy these privileges, and, in our opinion, this should be the universal rule.

The Medical Faculty in the Scottish Universities is a remarkable exception to the general rule. The other Faculties have monopolised the power, and have excluded Doctors of Medicine from a participation in the government of their University. The proposal to grant Parliamentary representation to these bodies, has roused the Medical Graduates to a sense of their rights. They have made their voice heard, and we rejoice that the Government Bill recognizes their just claims.

It is a sad instance of the illiberality sometimes met with, that the General Council of St. Andrews, a body of 368 educated persons, should oppose the admission of the Medical Graduates to equal rights with themselves. Certainly this says very little for the liberal training of St. Andrews.

The Medical Graduates of this ancient University are much more numerous than those of the other Faculties. They have contributed much more to its revenues, and they may be said to have some claim on the Government on account of the stamp-duty it has always imposed on their diplomas.

From 1836 to 1866, no less than 1993 persons obtained the degree of M.D., while only 242 graduated in Arts in the same period. The fees paid to the University by these Doctors of Medicine, amounted to £33,331, 5s.

The amount contributed by the Graduates in Arts was £762, 6s. The Government exacted as stamp-duty, £19,930 from the Medical Graduates, but let the others go scot-free. These figures are interesting, as showing the impropriety of the smaller number desiring to retain the monopoly of representation of the University. There has, we think, never been a more baseless pretence than that of the Graduates in Arts to ignore those in Medicine, or affect any superiority to them. Nothing but the blindness that too often affects those in possession, can account for the unwarrantable opposition that has been raised.

The transparent fallacy that residence ought to be demanded to confer the franchise, is simply ridiculous, when it is remembered that the University of London, the constitution of which is the most allied to that of St. Andrews, requires no residence in any Faculty. St. Andrews makes no provision for a medical curriculum within its own walls. It therefore cannot demand it from candidates for its M.D. degree. If residence be essential, then St. Andrews writes its own doom, for it would have no right to grant the M.D. to those who could not reside, and as it is chiefly a medical University, this privilege taken away, it would speedily sink into insignificance. It is useless to conceal the fact; those in possession are jealous of the intrusion of the medical graduates. But they should beware lest their jealousy destroy their hopes. It is the Medical Faculty which has in this, as in the other Scottish Universities, conferred the greatest renown upon them. It is to the influence of the Medical Graduates that the concession of Parliamentary representation is to a large extent due. Take away the Medical Faculty, and there is likely to be raised a voice against granting a member at all. Then the jealous Council will reap a reward it little anticipates.

There is a practical point connected with this question which should not be overlooked. Already anxious candidates—counting on the chickens that are being so slowly hatched—have solicited promises of votes. We warn graduates against being betrayed into hasty promises. As we have said, there are other candidates who will come forward at the proper time. There are medical candidates too, who think it premature to address an elective body not yet created, but who will not wait long after the royal assent shall have been given to the bill. It is well, therefore, to wait. But there is this further reason for delay. No candidate has yet pledged himself to support justice on this or any other question, and therefore in supporting any of those who have yet addressed them, the graduates may be voting for their own enemies.

To return to the arguments that have been advanced. We have already disposed of the plea of residence. We may add that the non-residential doctors of medicine are diminishing in number since 1863, since which only ten such degrees per annum are to be granted. Whether this new regulation is a wise one, with the example of the London University before us, may well be doubted; but we have not now space at our disposal to discuss it. We maintain merely that the medical faculty is the most important, its graduates the most numerous; that all are worthy of the franchise, and that the attempt to deprive them of it is as unwise as it is unjust. The rule of residence or non-residence ought to make no difference at all in the privileges which the degree once granted confers, and the raising of this point is only throwing dust in the eyes of those who are not familiar with the facts.

As to other arguments, we add the following extracts from the memorandum alluded to at the commencement of this article, and which will immediately be in circulation:—

"Seeing then that the Doctors of Medicine of St. Andrews are so numerous, and have complied with all the regulations of the University, their long-continued exclusion from the General Council must be considered unjust and unwise. But the injustice becomes much more evident now that St. Andrews in conjunction with the University of Edinburgh is about to be represented in Parliament. The Memorandum[1] submitted in February last to the Chancellor of the Exchequer set forth the claims of the Doctors of Medicine to the franchise, and the justice of the demand is now abundantly acknowledged. It could not be otherwise. It could not be seriously maintained that any body of educated men is fairly represented by the votes of one-fourth of the number of its members. But the same reasons, which show the right of the Medical Graduates to a vote for the Member of Parliament, are no less convincing proofs of their title to a seat in the General Council of their University; for it is only as Members of the University that they can claim the vote; and if they be members of the University, they cannot justly be

1 Printed *in extenso*, and commented on, in THE MEDICAL PRESS AND CIRCULAR, February and March.

excluded from the General Council, the common ground on which all Graduates should meet and from which all legislative action should arise.

"Springing from the argument based on want of residence, is the plea of want of interest on the part of the Medical Graduates in the welfare of the University. This needs little reply. Up to the present time the Doctors of Medicine have had no chance of evincing any interest in the University, for they have been unnoticed and unrecognised by it. But the rapid growth of the St. Andrews Medical Graduates' Association which already, before it is a year old, numbers upwards of 500 members, and whose professed object is to obtain for the Doctors of Medicine a seat in the General Council of the University and a vote for its representative in Parliament, is sufficient answer to the charge. The Medical Graduates are not, and cannot be, regardless of the interests of their University. Their reputation, and its, stand and fall together. With the credit of the University falls the credit of its degree, and the rank which it confers on its holder.

"Again, the admission of the Doctors of Medicine to the General Council has been opposed in the University itself on the ground that the number of the Medical Graduates is so great that the other Faculties would be overwhelmed by them. If the Doctors of Medicine have a just claim to be members of the General Council their number can but add to the injustice of their exclusion; and should be no bar to the exercise of the privileges which rightfully attach to every member of a University. But it must be recollected that the Medical Graduates are nearly all men in active practice who could not in large numbers leave their daily duties to attend the meetings of the General Council at St. Andrews. There have, indeed, been times when even two or three voices raised in that Council in defence of the University, as they would have been raised had the Medical Graduates possessed a voice in its deliberations, would have been of vital importance to its interests; as when an attempt was made to exclude it from representation in the Medical Council, and when its Degrees were unrecognised by the Poor-law Board. There are no conceivable subjects which can ever range the Doctors of Medicine in a body against the Graduates in other Faculties; they have no religious or political party ends to serve; their object is, to maintain and, if possible, to enhance the reputation of the Ancient Corporation of which they are Members; and they will never be aught else than an aid and a help to those of their fellow-Graduates in other Faculties, whose object is, like theirs, the good Alma Mater.

"The Doctors of Medicine of St. Andrews, then, claim the right of becoming Members of the General Council of their University, because they are the most numerous of the Graduates and should not be excluded from a voice in its Government; they claim it because they are really Members of the University, having complied with all its regulations, pursued the course of study prescribed for them, submitted to its examinations, and had its Degree publicly conferred on them; they claim it because their interest in the welfare, their stake in the prosperity of the University is great and vital, for their social and professional status depends, in the first instance, on the character of the Degree they hold, and the reputation of the University from which it is obtained; and they claim it lastly on the ground of simple justice, that they may have equal rights and equal privileges with their fellow-Graduates."

CERTIFICATES OF DEATH.

The Liverpool Medical Institution has very wisely taken into consideration the custom of signing certificates of death without seeing the dead body. It will be recollected that recently medical men have been entrapped into signing the certificate of the death of a person who was actually living. The object of this fraud was to use the certificate as a means of obtaining money from a burial or insurance society. Now that such a case has actually come before a court of law, we may hope that medical men will not forget the possibility of being imposed upon, and will take such precautions as shall prevent them from appearing in an unenviable position before the public. It is easy to understand how the present lax custom has grown up. No suspicion has been excited, and no thought bestowed upon the matter, but it is clear that the profession has a duty towards society in this matter. We know well enough that in the majority of cases no reasonable doubt can exist in the mind of the practitioner. It is common enough for a patient to be seen in the evening who cannot be expected to last till morning; then when next day told he is dead, and asked for a certificate, it is at once filled up, although the medical man cannot affirm of his own knowledge, that the patient is actually dead. This custom, we say, is comprehensible enough, because it does not seem reasonable to ask to see the body before signing such a certificate. There are, however, other cases of much less certainty, and we have had occasion to notice a degree of laxity in public practice which can find no excuse. We have seen certificates filled up by gentlemen who could scarcely call to mind the case which was reported to have terminated in death. Now, here the door is open to fraud by the deliberate act of the medical man, and we think it would be far more proper to refuse to certify at all in such cases. The registrar of the district would then have to satisfy himself that a death had taken place by other means; or, which would be more satisfactory, an inquest would be held by the coroner, and the cause of death returned by him.

QUIETING A SICK PAUPER.

A verdict of "not guilty" need not hinder us from drawing attention to the revelations as to Workhouse Infirmaries, made in the trial for manslaughter of Henry Harman, who is described as "a weak-minded creature," and who offered no defence.

It appears that the accused was an attendant in the Infirmary of Lambeth Workhouse, his duty being to wash the patients and put them to bed, but not to administer medicines to them. That arduous task was entrusted to the nurses. A patient named, Bagley, 68 years of age, who got his living by hawking groundsel and chickweed, was admitted into the Infirmary, with an attack of paralysis, which was declared by Dr. Bullen not to be severe. One Sunday the pauper patient is declared to have been troublesome. It was the nurse's Sunday out, and the attendant, Harman, who supplied her place, gave him, in the evening, a dose of morphine, from the effects of which he died the next morning. Some witnesses spoke of violence on the part of Harman towards the patient, but the gravamen of the charge was the administration of the drug. But how did he get this powerful narcotic? The answer to this question exhibits the management of the Infirmary in a light that reflects credit on no one.

The "morphine" spoken of was a mixture, not marked poison, containing ten grains of acetate of morphia and two drams and a half of Battley, in the bottle—said by the nurse to hold "*about* 14 ounces;" according to the same witness, this was kept with as many as 25 other bottles, on a shelf in the ward. This mixture the nurse seems to have given at her own discretion, and as she superintended 80 or 90 sick and convalescent paupers, we may imagine she gave it frequently under a notion that they needed something to keep them quiet.

Dr. Bullen was not apprised of the condition of the patient after he took the drug, and would have known nothing of the circumstance but for a statement made by a fellow-inmate as he went his rounds. More surprising still, the house-surgeon who lives on the premises was not

informed of the patient's condition after he became insensible.

Mr. Justice Willes summed up in favour of the prisoner. He thought it would be hardly safe to convict this ignorant man, unless the jury thought him guilty of criminal misconduct. Such criminal misconduct must consist of the negligent administration of a thing which he knew, or ought to have known, to be of a deadly character.

So then it is again laid down that a reckless man may plead ignorance, as his excuse for giving to persons under his care a deadly poison. A medical man or a dispenser who had acted thus, would have been guilty of criminal misconduct. We do not desire to see a poor "weak-minded creature," who is able to "make no defence," hastily punished; but we do ask the guardians of the Lambeth Workhouse what right they have to intrust the care of their Infirmary to such persons? The insufficiency of the nursing arrangements could scarcely be more manifest than in the substitute thus provided for the one nurse to whom is intrusted the care of eighty or ninety sick paupers. We wonder if any one of these guardians has ever been ill himself, and if so, whether he considered the 90th part of one nurse's time sufficient attendance during that illness? Further, would he have liked to be served to a composing dose out of a bottle kept on a shelf with twenty-five others, by a "weak-minded creature," who had not heard that a tablespoonful was enough for a dose? We certainly think this case calls for further inquiry, although it is, we are well aware, but an example of what is daily occurring in the workhouse infirmaries of the kingdom. But cases like this attract public attention, and it is as well they should be thoroughly sifted.

Notes on Current Topics.

The Public Health.

LITTLE variation occurs in the return of the Registrar-General. There were registered in London and thirteen other large towns of the United Kingdom, 4848 births, and 2993 deaths. The annual rate of mortality was 24 per 1000 persons living; 23 in London and Edinburgh; 20 in Dublin; 19 in Bristol; 25 in Birmingham; 26 in Liverpool; 32 in Manchester; 23 in Salford; 24 in Sheffield and Bradford; 25 in Leeds and Newcastle-upon-Tyne; 17 in Hull, and 31 in Glasgow. The deaths registered in London amounted to 1392, which corresponds exactly with the average number.

The deaths from zymotic diseases were 311; 23 deaths from small-pox; 66 from measles; 29 from scarlatina; 12 from diphtheria; 56 from whooping-cough; 40 from fever, and 13 from diarrhœa were registered.

One hundred and sixty-seven deaths occurred from phthisis; 142 from bronchitis; 77 from pneumonia; 64 from diseases of the heart; and 150 from diseases of the brain and nervous system.

Ten infants and one adult died from suffocation; 4 persons from burns or scalds; 5 from drowning; 7 committed suicide; and 7 were killed by horses or carriages in the streets.

New Hospitals for London Paupers.

SIXTY gentlemen compose the members of the Metropolitan Districts Asylum Board. These have formed themselves into committees for the management of the different objects contemplated by the Board. Besides those who will direct the purchase of sites and the erection of the buildings, there are others for finance and general purposes, so that each gentleman of the Board is engaged in one method or other in carrying out the benevolent designs of the organization. General action has not been taken at present towards building the various asylums in consequence of obstacles which cannot be immediately removed. The Committee for Imbeciles are the first to begin. They have purchased two sites for hospitals for this class of paupers—the one at Leavensden, eighteen miles north of Charing-Cross, and the other at Caterham, fourteen miles south of that terminus. Sites have been selected at Homerton and Hampstead by the committees for fever and small-pox, but that for the southern district has not yet been purchased, the neighbourhood being so generally built over. The buildings are to be adapted in the most complete manner to the wants, well-being, and health of the patients, as far as is consistent with strict economy in the erection and management of every portion of the system. The plans of the buildings have been prepared, the committees are vigorously pursuing their work, and there is every prospect that our metropolitan parishes will be furnished with institutions of the best possible construction, which will enable them to take proper charge of their sick poor, and provide for their necessities in the best and most inexpensive manner.

Eastbourne Convalescent Hospital.

ALTHOUGH this institution was established only four years ago, it has very rapidly increased in importance and efficiency. It receives now as many as 100 convalescents, and thirty incurables. It was estimated that the expenses of the building, and all things requisite for carrying out the design would amount to £30,000, towards which sum only £16,000 have at present been raised. A concert was given for the purpose of augmenting the funds, at which about seventy amateur performers volunteered their services. Several interesting pieces were sung in excellent style, the result of which was that a considerable sum was collected towards the requirements of the hospital.

St. Thomas's Hospital and Medical School.

ON the day of our present issue, the 13th May, at half-past eleven in the morning, the foundation stone of this hospital will be laid by Her Majesty the Queen. The site is on the south bank of the river, between Westminster Bridge and Lambeth Palace. The situation seems everything that can be desired. The proposed number of beds is six hundred, besides those for sisters and nurses, and the plan of construction contemplates every accommodation for the comfort and requirements of the patients, with regard especially to space and convenience. In the most northerly part of the building, the treasurer's office, the board-room, and other places of business will be situated, and in the most southerly, the medical school; while the hospital proper will occupy the centre. At the rear will be placed the surgery, the dispensary, the out-patients' room, and the baths. The whole premises will comprise an area of not less than eight acres. It is calculated that the whole expense of the undertaking will not be less than £500,000. As it is one of the most important of our institutions, and, moreover, will be the last built, it bids fair to be the most imposing structure of the kind in

the kingdom. Nearly every member of the Royal Family is expected to be present at the ceremony.

Professor Roscoe at Apothecaries' Hall.

THE second lecture on Spectrum Analysis was delivered, according to the programme, last Saturday afternoon. The great hall was again as densely crowded as on the prior occasion, but owing to the authorities having adopted our suggestion to attempt a little more ventilation, nothing was left to be desired. During the week an entirely new arrangement for darkening the room easily and rapidly had been carried out, in a manner at once simple and effective.

The Apothecaries' Society has always shown itself ready to adopt any suggestion, and we have, therefore, great pleasure in recording the success of this experiment. The Society deserves the thanks of the Profession for bringing out this course of lectures, which, we hope, may be but the forerunner of others. The time chosen too, is evidently more favourable than the later hour, which so constantly operates in keeping away visitors at other institutions.

Professor Roscoe devoted his second lecture to the appearances produced in the spectrum by the alkalies. The lecture was illustrated by many experiments.

The Strand Guardians Again.

THE Board seem to have fancied that they could pay Dr. Rogers his salary up to the time of his suspension, and cry quits. But Dr. Rogers did not see the force of this, and indignantly refused anything less than the amount due up to the time of his dismissal. Legal advice having been taken, Dr. Rogers has been paid up to the time he and everyone else expected. His right having ever been questioned is a sufficient indication of the composition of the Strand Board.

Died at his Task.

IN Norkitten, a little town of one of the Western Prussian districts in which the starvation-typhus is ravaging, Dr. Hermann Bartsch died, attacked by the tremendous disease. This is the seventeenth physician that has fallen a victim during the present epidemic in the Western districts of Prussia.

Carbolic Acid.

SEVERAL cases of poisoning by this substance have lately been reported. In some the stomach-pump was tried with little or no effect. We have heard that some cases have been treated with success by sweet-oil and castor-oil. The oil should be administered promptly in a full dose, and it would be advisable to repeat it three or four times. We hope that greater success may attend this practice than has yet done, that of evacuating the stomach. The carbolic acid acts rapidly as a caustic on the tissues.

Vaccination Returns for Scotland.

FROM the returns of the Registrar-General of Scotland, we find that in the year 1866 no fewer than 96 per cent. of the surviving children have been vaccinated. Of the remainder, 0·56 per cent. had vaccination postponed from ill-health, the same number were insusceptible of vaccination, and the remainder had either left the district, or were not accounted for. Very few, therefore, would be exposed to the attacks of small-pox. These, however, belong to the ignorant class, and may, consequently, spread the disease should they be attacked. Still the Vaccination Act has worked much surer in Scotland than in England. Thousands have been the victims of small-pox in England, but it produced in Scotland only 131 deaths in 1865; in 1866, 300; and in 1867, only 124.

Principalship of Edinburgh University.

THE 18th of June has been fixed upon as the day for electing the successor to Sir D. Brewster. Of the several names that have been mentioned that of Sir J. Y. Simpson is the one that the medical and scientific world would like to see thus honoured. We fear, however, this is not to be. The University will not gain anything by passing over the claims of her great medical baronet.

THOSE interested in the coming International Maritime Exhibition at Havre, may be glad to hear that it is proposed to add to it a Medical Congress to come off in August. Further information will be given on application to M. de Lavergerie, 5, Crosby Hall Chambers, Bishopsgate, E.C.

THE LONDON HOSPITAL DINNER.

THIS great and important charity celebrated last week its 128th anniversary by a dinner, over which the Right Hon. W. E. Gladstone, M.P., presided, and at which about £7000 were added to the funds. It is superfluous to say that the claims of the hospital were ably pleaded by the distinguished chairman, who also mentioned that at the College of the Hospital scholarships are about to be founded to encourage the study of medicine in this unrivalled field. Nearly all the medical and surgical staff of the hospital were present at the dinner and most of the lecturers at the College. We also observed several of those who have retired from that sphere of labour, but who evidently retain a warm interest in it. The usual loyal toasts having been drunk with enthusiasm, the right hon. gentleman proceeded to the toast of the evening. He said his claim to take the chair on that occasion had arisen from his connection with one of the several subsidiary establishments which had been called into existence by the London Hospital—he alluded to the recently-established convalescent hospitals, which every enlightened man must perceive to be, in the case of this great metropolis, an essential portion of any rational scheme for the health of its inhabitants. It rarely happened that persons engaged like himself in a sphere widely different from that in which those connected with this hospital were occupied, undertook the task of commending to public notice institutions of this character; but in his case he could assure them it was from want of opportunity and not from want of will. It might be invidious to make comparisons, yet he might say that in certain respects, amid all the sister institutions, the London Hospital could present to the notice of the public of the metropolis a paramount and an unrivalled claim. The first ground of such a claim arose from what seemed to be a law governing the construction and organization of the vast and almost immeasurable city in which they were living. What one would desire would be that the growth of London should harmonize with the expansion of the various orders and ranks of which a Christian community was composed, so that those who were in the higher stations of life should be at hand ready to administer to the wants of their poorer brethren. But, on the contrary, the law by which the growth of London appeared to be regulated was that its wealth and grandeur should concentrate more and more towards the west, while the labouring community should tend towards the rising sun. The social consequences of this habitual system were very remarkable. It removed from the scene in which the wealthy and the great resided, and whose dwellings ran through continuous streets and squares inhabited by the upper and middle classes, all physical evidence of want and privation, and exhibiting to them no signs of the never-ending struggles of their fellow-men against the evils and miseries of the world. He knew not of any mode by which the general growth of London could be suppressed, and the tendency of this separation of the rich and the poor be arrested; but as a practical measure he thought the best thing that could be done was in every way to encour-

age by individual and combined efforts these benevolent institutions, which might happily bring about a restoration of that link of Christian and human charity which alone could bind together the extremities of society. The right hon. gentleman then pointed out the peculiar nature of the diseases which the London Hospital from its locality had chiefly to relieve, and which he described to be in the great majority of cases accidents. The total number of in and out-patients received during 1867 was 38,776; of these nearly 16,000 were cases of accidents, so that beyond all dispute the London Hospital was an hospital for accidents, and he would also call it a free hospital, for out of the 38,776 patients relieved during the year, 22,308 were free patients—that is, they did not require any recommendation for admission to the hospital.

Having thus pleaded for the hospital, Mr. Gladstone turned to the college, which really stands in need of assistance to enable it to establish the scholarships proposed. He pointed out that in deciding on founding such scholarships, the authorities were only legitimately completing the scheme for rendering the hospital useful to the whole community. The Council, he said, had selected for the designation of the scholarships the name of the late chairman of the house committee as a just mark of gratitude for his great and long-continued services to the hospital; so that they are called the Buxton Scholarships—a name which had been for several generations associated, both in the city of London and over the wide world, with every civilized, Christian, and philanthropic purpose. A sum of £2000 is needed to establish these scholarships. Less than £800 has at present been subscribed, but no doubt further assistance will soon be forthcoming, and hospital and college may both look for a continued period of prosperity.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

APRIL 2, 1868.

PRACTICAL REMARKS ON THE TREATMENT OF SOME OF THE DISEASES OF THE GENITO-URINARY ORGANS.

By W. F. TEEVAN, Esq., B.A., F.R.C.S., &c.

MR. TEEVAN commenced by stating that he intended to divide the subject of the evening's discourse into four parts:—1. Spermatorrhœa; 2. Stricture of the urethra; 3. Irritable bladder; 4. Stone in the bladder. He however would on this occasion be only able to notice the first two subjects, as the evening had already been considerably shortened by some communications.

The author related the various opinions regarding spermatorrhœa, showing that whilst it was recognised as a complaint *per se* in France, its existence in this country was almost ignored. According to M. Mercier, spermatorrhœa was very common, and resulted generally from, and was a symptom of, indigestion. Mr. Teevan went fully into the causation and pathology of the complaint, as related to him personally by M. Mercier, and narrated two well-marked cases which had come under his own notice, and in which the existence of true spermatorrhœa had been clearly proved by microscopical examination of the urine, which showed that spermatozoa were passed, unconsciously to the patient, in the day and night urine. There were four causes for spermatorrhœa:—1. Indigestion; 2. Excess in venery; 3. Local irritation; 4. Masturbation. The complaint was common in cases of disease of the brain and spinal cord.

The treatment of the complaint varied according to its cause, and also whether it was the primary functional disorder, or merely secondary. When it resulted from indigestion, a cure would be obtained by removing the dyspepsia, and by local treatment—electricity and mild injections of nitrate of silver (gr. v. to gr. x. to the oz.). If it was caused by excess in coitu, it might be removed by large doses of tinct. ferri. sug. (℥j. to ℥iss.), given three times a day, and by cold bathing: this latter remedy was, however, very powerful, either for good or for evil, and ought not to be used unless there was well established reaction. Horse exercise, carriage exercise, and walking, were all bad, and ought to be avoided, as the blood was determined to the pelvic organs. Gymnastics and rowing, or the use of dumb-bells, were the best kinds of exercise.

Mr. Teevan then proceeded to his second division, and explained the causation and pathology of stricture of the urethra, and stated that no attention whatever had been paid to that most important fact—the detection of stricture in its earliest stage, and thus entirely obviating any operative interference. He showed how strictures could be recognised by the use of the "bougie à boule," years before the generality of surgeons would find out the existence of the complaint.

There were only two philosophical and surgical ways of treating stricture of the urethra—either by gradual dilatation or by subcutaneous division. Most strictures are best treated by the use of the French "bougie olivaire." The author said he was the first to introduce these instruments into English hospital practice, and no one who had ever used them would ever return to the English ones. The instrument pictured in the *Lancet* of January, 18th, and called "bougie à boule" by Sir Henry Thompson, was not such, but was the "bougie olivaire." The former was for the detection of stricture, the latter for its treatment.

Dr. DRYSDALE complimented the author on his paper, and said he was extremely glad to find that Mr. Teevan had taken up the subject of spermatorrhœa, a complaint entirely ignored through the indifference of the profession, and trusted that it would be rescued from the hands of ignorant quacks. He said he thought it would perhaps be found that spermatorrhœa, instead of being a symptom of indigestion, was a cause. He should be glad to know what objections Mr. Teevan had to the forcible rupture of stricture.

Dr. COCK would be glad to know what was the dose of the iron which Mr. Teevan gave, and he should also like to hear what objections there were to the use of dilators.

Mr. COULSON confirmed Mr. Teevan's praises of the "bougie à boule" and the "bougie olivaire," and said he was now often able to detect a stricture as a cause of gleet, whereas formerly he had often failed to cure that complaint—not being able to recognise its cause. He, however, differed from Mr. Teevan in preferring the use of the metal instruments in those cases of stricture which were old and cartilaginous.

Dr. CAMPS said he did not think that masturbation was nearly so common as supposed, and believed that spermatorrhœa was a rare complaint, and that the peculiar morbid dreams to which Mr. Teevan alluded existed in other complaints.

A Member said he had been very much interested, and hoped that Mr. Teevan would at a future meeting of the society favour them with his observations on the two subjects which he had not been able to touch on.

Dr. GELSTON stated that he had become acquainted with the "bougie à boule" and the "bougie olivaire," through Mr. Teevan, and he would never again use the English instruments.

Mr. TEEVAN, in reply, stated that small doses of iron were useless in spermatorrhœa: the sesquichloride must be given in doses of ℥j. to ℥iss., and it would be found that it rarely caused any inconvenience. Forcible dilatation of the urethra was of but little use, inasmuch as it had to be preceded and followed by gradual dilatation. Nothing at present known could excel the treatment of stricture by means of the "bougie olivaire," for to it no stricture was impassable. It caused no pain or inconvenience to the patients, who might be cured without losing a drop of blood or a single hour's work.

Mr. Teevan then demonstrated, by means of the endoscope illuminated with the lime-light, the interiors of several living human bladders.

AT THE MEETING OF 16TH APRIL,

MR. ERASMUS WILSON read a paper on Morphœa or Vitiligo, giving the statistics of twenty-five cases which had occurred in his own practice, together with the pathology, the etiology, the prognosis, and the treatment of the disease. He prefaced his narrative by attributing disease in general to a lowered state of vital power, the latter constituting a *causa morbi*. Such *causa morbi* being engendered, it might give rise in twenty individuals to as many different diseases; or, in the same individual, by attacking different organs, to a series of diseases; for example, bronchitis, diarrhœa, rheumatism, or eczema. When these affections succeed each other separately, that which follows obtains the credit, popularly, of having been the cure of its predecessor; and in the same way, if the first disease should be an external affection, and the second a disorder of an internal organ, the disease is popularly supposed to be *driven in*. The skin, like the body in general, is made up of a number of different structures, and these structures may be affected by a *causa morbi*, separately or collectively. Morphœa attacks the whole of the tissues of the skin, beginning by an altered state of the nerves; the capillaries then become obliterated; there is loss of sensation and circulation; the capillary structure is effaced, the epidermis changed in char-

acter ; secretion is arrested, and the hairs fall out or are altered in colour to white. The pathological process in operation in the production of these changes is a hyperplasia of the white fibrous tissue, a substitution of a lowly organised tissue for a higher tissue, in a word, *fibrous degeneration* of the skin.

The general characters of morphœa are—a spot in the skin, which is white, more or less insensible, smooth, hairless, circumscribed, and permanent ; and it presents itself to our observation, sometimes in the form of a thickening and condensation of the skin, and sometimes as a withering, or atrophy. Hence its distinction into morphœa tuberosa, and morphœa atrophica ; the former is commonly remarkable for a whiteness which is comparable to ivory, hence, also, the term morphœa alba ; while occasionally, and more commonly in morphœa atrophica, there is an increment of pigment in the rote mucosum, morphœa nigra. A portrait of a little boy, the half of whose face was affected by morphœa, was exhibited to the Society, in order to illustrate the various forms of the disease : on the cheek was seen morphœa tuberosa and alba, and on the forehead morphœa atrophica and nigra.

The disease begins as a lilac-tinted erythema ; in the centre of which the white spot, the *leuke* of the ancients, appears; the white spot is sharply defined, and is encircled by a suffused halo of lilac-redness, often of the tenderest hue. Sometimes a sensation of heat, sometimes a tingling or itching, accompanies the pathological change, at other times it is discovered only by chance; and however much deformity it may occasion, it never gives rise to pain.

Of the 25 cases observed by Mr. Erasmus Wilson, 5 only were male ; 20 occurred between the ages of 10 and 40 ; the ages between 20 and 30 being those in which the greatest number were found ; this estimate of age corresponding in the female with the most active period of uterine function ; 15 out of the 20 female cases being attributable to sexual causes in which the uterus was concerned—namely, 9 pregnancy, and 6 menstruation.

Like most affections of neurotic origin, morphœa is very commonly unilateral, 11 of the 25 cases presenting this character; its most frequent locality is the trunk of the body, more especially the clavicular and sub-mammary region.

It is always chronic in duration, one case having been under observation for 31 years, one for 15 years, one for 12 years, and eleven for 5 years. And in a few instances it evinces a proneness to recovery, and spontaneous cure, occasionally getting well on one spot, while another may be in progress of formation.

While, therefore, this remarkable affection must be looked upon as being pathologically a retrograde, metamorphosis of the tissues of the derma originating in neuro-paresis, it must be regarded pathologically as a debility and aberration of nutritive power, in a word, a nutritive debility. Hence, the treatment should consist of those means which are known to improve nutrition and sanguification ; for example, a rational hygiene, cod-liver oil, iron, and arsenic, together with mild, discretient and stimulant, local remedies, and an encouragement is held out of the probable success of these remedies by the fact of the occasional occurrence of spontaneous cure.

MEDICAL SOCIETY OF LONDON.

27TH APRIL, 1868.

DR. RICHARDSON, F.R.S., President, in the Chair.

THE new law declaring that extra-urban Fellows shall be admitted on payment of entrance fee only (without annual subscription), was read from the chair.

Mr. FRANCIS MASON exhibited for Messrs. Weiss, a new speculum for facilitating the performance of operations upon the uterus and vagina.

Mr. WEEDEN COOKE exhibited a drawing, and narrated a case of large ranula.

Mr. HENRY LEE read a paper on a case of syphilis communicated to a wet nurse, and on vaccino-syphilitic inoculation. He wished to direct the attention of the Society to those secretions which were as distinguished from those which were not the means of conveying the disease. The secretions from secondary symptoms, and especially from secondary symptoms as they appeared on mucous surfaces, would convey the disease ; and Mr. Lee cited at length a case in which it had been so communicated from a child to a healthy wet nurse. But he maintained, on the other hand, that no proof had hitherto been afforded that the milk from the breast, the pure vaccine lymph or even the pus from the "pustule of inoculation," ever had been the means of communicating secondary syphilis. It was well-known that the syphilitic poison after it passed through the inguinal glands became altered in some way, so that it no longer affected the lymphatic glands second in order or nearer the centre of the circulation. He believed that circulating fluid, after undergoing an elaboration in the mammary gland in the vaccine vesicle, or in the pustule produced by inoculating the secretion of a suppurating sore, underwent an analogous period of action, that these several secretions were no longer capable of giving constitutional syphilis, although the blood whence they were derived might do so. It was necessary he (Mr. Lee) said to draw an accurate distinction between the suppurating sore and the indurated sore. The secretion of the latter would of course, if inoculated in a virgin constitution, produce an indurated sore, which would be followed by secondary symptoms ; but he believed that it had never yet been proved that the inoculation of the pus, which appears four or five days after contact in the specific pustule, would produce the same effect. Mr. Lee invited the co-operation of the Society in the investigation of the laws of the transmission of secondary syphilis—the three points which he had stated, although at first sight, having no very evident connexion, yet pointed to a general law, and societies as well as individuals, he thought, might, by accumulating facts, follow out the true inductive reasoning, whether after a longer generalisation we should be able to establish the law that no secretion after it had been elaborated, in a gland, from the blood could convey the poison contained in that blood. He (Mr. Lee) did not know, but the facts ascertained, as far as they went, appeared to him to point to the idea that the natural secretions elaborated in the different glands of the body cannot communicate syphilis, and that the products of morbid poisons elaborated in the body (other than that of true syphilis) cannot communicate that disease. The author dwelt at some length upon the subject of vaccine syphilitic inoculation, and considered that when syphilis had thus been communicated, as it doubtless had been on the Continent, it was through the blood or some other fluid having been inoculated in addition to the pure vaccine lymph. He had not seen an instance of syphilis having been communicated by vaccination in England, and this he attributed to the abundant supply of vaccine lymph and to the care which English medical men bestowed upon the operation.

Dr. DRYSDALE said that it was an interesting fact that Mr. H. Lee, with his large opportunities, had not seen a single case of communication of syphilis by vaccination. He narrated a case which seemed to him an undoubted example of such communication. (This case has been reported in the *British Medical Journal* for April 25, 1868.) He said it was indeed fortunate that inoculation of so formidable a disease as syphilis to infants took place so rarely in this country. There was, however, no doubt concerning the epidemics of Rivalta, and more recently of Morbihan, in France, as related by M. Depaul. All who are familiar with the way in which syphilis is contracted, must see that vaccination from an infected child is likely to spread the disease. He had seen the disease propagated by the most trifling modes of communication. With regard to Mr. Lee's remark about the infection not being derived directly from the seminal fluid, he could not coincide with this, since he had, in some cases, seen the child of an infected man syphilitic, and its mother escape, and he had also seen cases where the husband had long been free from disease, and the fœtus and mother became infected, although he agreed with Cullerier and Simonet, of Paris, that such cases were exceptional. His friend, Mr. R. W. Dunn, had met with two cases of vaccino-syphilitic inoculation.

Dr. BALLARD repudiated the inference drawn by the last speaker, that the case which he had narrated was of true vaccine syphilis. When syphilitic virus is inoculated with vaccine, there is—First, a vaccine vesicle ; second, a chancre. In his case there was no primary sore, but a manifestation of constitutional syphilis ; anything which will disturb the *status quo* of the constitution, may occasion the manifestation of hitherto latent syphilis. In the case quoted, the disturbing cause was the vaccine fever. The child, no doubt, was syphilitic, either hereditary or casually, prior to vaccination ; had it been otherwise, a primary lesion would have occurred at the seat of the punctures. He understood Mr. Lee to say that while syphilis could not be imparted by inoculation of pus derived from the product of syphilisation, it could be imparted by the blood thereof. This, if true, confirmed the view held by some, of the danger of imparting syphilis when blood is drawn in taking lymph from a syphilitic vaccinifer. He believed that all had

abandoned the view that the virus of syphilis was contained in the normal contents of a vaccine vesicle. In proof of this M. Sebastian Beziers vaccinated from a syphilitic child without drawing blood. By accident blood was drawn and mixed with the lymph used in making the last puncture. In this spot only a primary sore appeared, the others presenting true vaccine vesicles.

Mr. FRANCIS MASON narrated a case of a woman, undoubtedly syphilitic, nursing a perfectly healthy child.

Mr. WEBB inquired if it were possible to take vaccine virus, which can be said, with absolute certainty, to contain no blood element.

Dr. ROGERS said that if the knowledge can be disseminated, that vaccination from even syphilitic cases can be performed without the propagation of syphilis, a most valuable effect will be produced. He was certain that virus could be obtained without the admixture with blood.

Mr. MARSON could only present negative evidence. Out of 60,000 vaccinations observed by himself, there was not a single case of syphilis so communicated. He considered that the French experiments had been carelessly performed.

Mr. HUNT had seen 1000 cases of infantile syphilis, not one of which could be traced to communication through vaccination.

Dr. SANSOM mentioned a case which he concluded to be one of vaccino-syphilitic inoculation, because—1st. The syphilitic manifestations, which were undoubted, occurred with such a direct relation in point of time to the performance of vaccination, as to give the greatest probability of the causative influence of the latter ; and 2nd. His ultimate knowledge of the history of the parents allowed him to state absolutely that they were not syphilitic. He asked if any could believe the blood corpuscle to be the contaminating medium, for if not it would be impossible to tell from the inspection of virus whether it might be noxious—the question of admixture with blood became therefore of no great practical moment.

Dr. OPPERT said that ten years ago a physician attached to an hospital at Moscow, asserted that syphilis might be *cured* by vaccination ; in slight modified eruptions which resisted treatment, vaccination brought out the latent syphilis to the surface—these views supported those of Dr. Ballard as regards the disturbance of the system by vaccination. In Dr. Drysdale's case there was a missing link, it was not certain that the lancet with which the child had been vaccinated was pure, nor was the child under medical observation during the period of vaccinia. In Italy, too many subjects were vaccinated from one vaccinifer. Mr. Marson's remarks on continental carelessness were too sweeping. In Prussia great care was taken, but in Russia and France lady vaccinators (the midwives) existed.

Mr. WOOLF, in doubting the efficiency of the records of cases of vaccino-syphilitic inoculation, narrated a case in which he had observed secondary symptoms, though the possibility of syphilis in the case was stoutly denied ; the most searching investigation is necessary, in every case we must be insolently critical.

Dr. CHOLMELEY also considered the cases of so called vaccino-syphilis very imperfect ; the only direct evidence could be a chancre at the seat of the vaccino-puncture.

Mr. DE MERIC said that in his mind there was not the slightest doubt that syphilis *could* be transmitted by vaccination. It is dangerous to reject the records of facts coming from France, Italy, and Germany ; this country has been fortunately free, though even here isolated cases have occurred. Eruptions sometimes after vaccination afford no proof. To carry conviction the vaccine vesicle must be seen to take a chancrous character. The negative testimony of vaccinators of great experience is entitled to every respect, but the very multiplicity of their operations weakens that testimony, they must lose sight of many of their patients. Mr. De Meric believed the lymph of the vaccine vesicle of a syphilitic child could convey the disease, he thought also that pus was capable of infecting ; as shown by Erbsot, a drop of lymph from a secondary papula was sufficient to impart syphilis. In fact, pathological secretions should be looked on with more suspicion than blood, which is at all events a pysiological product.

After some observations by Mr. Weeden Cooke, Mr. Marshall, and Mr. Ebsworth, whose testimony tended to negative the possibility of vaccino-syphilitic inoculation,

Dr. MARSTON said he thought such cases must be excessively rare, though he believed the contagion of syphilis might be conveyed through vaccination (facts which he considered proved by the cases at Rivalta and elsewhere) he did not think cases here related conclusive. The poisons of vaccine and syphilis were definite things, and produced definite series of effects occurring in regular succession. Vaccine and syphilis do not give rise to a hybrid disorder. Vaccine disease commences at the second day from the puncture, and runs its well-known course ; the earliest effect of syphilis is from ten days to six weeks after inoculation. The fluid in the Jennerian vesicle according to his (Dr. M.'s) observations is homogeneous up to the 8th day, and not cellular till the phenomena of inflammation are superadded ; how far it was true that the secretions, whether physiological or pathological, could convey syphilis, we are not yet in a position to affirm.

The PRESIDENT said it was impossible that the discussion of this evening would be fruitless, the opinion of the great majority of authorities, and the mass of direct evidence, tended to the conclusion that vaccination does not convey syphilis, and the minority have not sufficiently eliminated, *per contra*, facts.

Mr. HENRY LEE said, that notwithstanding the observations of the President, he was perfectly assured that such a thing as vaccino-syphilis does exist, physiological products (exudation) are more likely to be a contaminating media than pathological products (elaborations).

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

BELFAST BRANCH.

THE stated quarterly committee meeting of this local branch of the above society was held on Wednesday, the 6th instant, Dr. T. H. PURDON, the permanent president, occupying the chair.

Amongst the other members present were—Dr. Patterson, Dr. James Moore, Dr. Keown, R.N., Sydenham; Dr. Drennan, Dr. Whitaker, and Dr. R. Stewart, the honorary secretary.

Next month being the annual meeting of the society in Dublin, and when grants are made to proper objects for its assistance, several cases came before the local committee here to-day for consideration; and each having been carefully examined into, and found correct, all were approved of and signed by the president, for transmission to the general secretaries in the metropolis. The subject of taking more energetic steps to increase the number of subscribers, both in town and the country districts, was largely discussed, it being considered a matter of surprise that so few, comparatively, in Belfast, should give their aid, and still fewer outside its boundaries. The fact, too, of Antrim and Down, the sphere of action of this branch of the society, mustering so many on their roll of the "great and high-born," a larger proportion of whom might reasonably be expected to "shed the light of their countenance" upon a society so beneficent in its objects; yet, with but two or three bright exceptions, no substantial proof is given by that exalted class of any sympathy for the prosperity of so valuable and important a society. In regard to the town collection of subscriptions, Dr. Patterson, Dr. James Moore, and Dr. Browne, R.N., treasurer, were requested to undertake that duty at their earliest convenience, and report to next meeting. The country members of the committee were earnestly called upon to use their best exertions for contributions in their respective localities, and report progress also ; Dr. James Moore being at the same time appointed a deputation, as he had kindly consented to be on former occasions, to visit some of the more remote places of the district, on behalf of this branch.

The following subscriptions were now reported to have been received :—Dr. C. D. Purdon, £3 ; Dr. Drennan, £1, 1s. ; Dr. Ross, Ballymena, 10s. ; Miss Patrick, Ballymena, per Dr. Ross, 10s. ; Surgeon John Smyth, Belfast, 10s. 6d. ; Dr. Keown, R.N., Sydenham, 10s. 6d. ; Dr. Warwick, Belfast, 5s.; Dr. Filson, Potaferry, £1 ; Dr. Scott, Rifle Brigade, £1, per Dr. Filson ; Dr. Jamison, Newtownards, £1.

A letter having been read from the general secretaries in Dublin, requesting a report of the proceedings of this branch for the past year to be embraced in the annual report of the parent society, and some further business having been transacted, the marked thanks of the committee were given to the president in the chair to-day, for his continued lively interest in furtherance of this branch's operations and munificent pecuniary aid, and the meeting separated.

Correspondence.

INQUEST ON A CASE OF POISONING BY OXALIC ACID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I send you herewith a report of an inquest on a case of poisoning by oxalic acid, which is remarkable in many respects:—

1st. The patient took three-fourths of an ounce avoirdupois.

2nd. She died in ten minutes afterwards, or shortly after.

3rd. She *tested* the contents of her own stomach.

4th. She vomited *almost all* the poisonous material, as the *coats* of the stomach retained by *absorption* only two grains of the oxalic acid.

5th. There was *nothing to be found* in the contents of the stomach, which were merely *effused* blood.

The stomach was *intensely red* and *inflamed* in that short period.

I say that *she tested* the contents of her stomach by having vomited into *a bucket of water*, having a great quantity of lime in its solution.

"The vomited matter was like milk" when seen on the floor, "and when she vomited into the bucket" *it appeared to turn the water into milk.*

This did not come out in evidence, as the girl vomited into the pail in which they were in the habit of washing the glasses and cups used in the bar, and of course the landlord did not want to damage his business by giving such evidence.

The floor was *wooden*, not of stone; so that, as the oxalic acid was dissolved in *hot water highly charged with lime*, and it acted as an instantaneous emetic, it came up almost as it was swallowed, *a milky-looking fluid*, still capable of precipitating a large quanity of lime.—I remain, &c.,

WILLIAM BIRD HERAPATH.

From the account sent by Dr. Herapath, published in the *Bristol Daily Post*, we extract the following as the professional evidence, omitting those portions which are so clearly described in our correspondent's letter.

It having been proved that deceased had sent for and obtained the poison, had taken it, had shortly died, &c., &c.,

Dr. HERAPATH, F.R.S., deposed as follows:—I was called in to the deceased a little after seven o'clock. I arrived about half-past seven o'clock, and she was then dead, and had been dead some fifteen minutes. I was told that she had been vomiting, and vomited matter was shown me. The vomit was a very remarkable one—mucus, with curdled, dark stuff—which led me to suspect altered blood. There did not appear to be any particles of food in the vomit. I have since examined the vomit, and I have found oxalic acid in small quantities in it. I have obtained crystals from the vomit, so small, however, that it required the microscope to discover them. Yesterday I made a post-mortem examination. The body was well nourished and healthy. The deceased was not pregnant. All the viscera were healthy. I have examined the stomach. It presented an intensely blood-red appearance, and the fluid contained in it was blackened, curdled, altered blood. There were some very small white patches existing on the stomach, and the vessels were braced out and darkened as if by hardened blood. The blood was so altered in character that it was in fact insoluble. If the oxalic acid had been taken in water strongly impregnated with lime salts the white appearance presented by the vomit would be accounted for, as the lime would be precipitated as oxalate of lime. I have never seen an instance of poisoning by oxalic acid before, but I have experimented upon animals. It is a very rapid case of poisoning—one of the most rapid on record. I have no doubt that she was poisoned by oxalic acid. The deep colour of the stomach was caused by the intense irritation, and next by the exudation of blood. The precipitation, darkening, and curdling of the blood are the first symptoms produced by this poison. One-sixth of the quantity taken in this case is recorded as having killed a person, and the shortest time on record is eight minutes. The time in this case, I should think, was about 15 or 20 minutes.

Mr. PESTER—No, I don't think it was so long as that; not more than ten minutes. Mr Pester also stated that the water drawn from his well, and used in his house, contained lime in large quantities.

Dr. HERAPATH—I have not analysed the contents of the stomach. She died unquestionably from collapse, which would be produced by oxalic acid. The acid dissolves slowly in cold water, and hot water would have caused it to dissolve quicker.

EMMA THOMAS, re-called—Miss Salmon asked me to go for the acid just before seven o'clock. I think it was about half-past six o'clock. I use it nearly every morning myself. There was a small quantity of acid in the house.

ANDREAS GROVE, a Dane, living at Cardiff—I am married to deceased's sister. I last saw her about the beginning of November. We were not on very good terms with her. She had been an inmate of my house off and on since 1858. On one occasion she threatened to stab my wife, and took up the knife to do it. She had received no provocation. She was very excitable, and uncommonly passionate. I upbraided her, and she threatened to go and drown herself. I brought her back again, and maintained her for some time. Her temper was very bad, and my firm belief is that the girl has been insane for years. In September I took her out for a walk on the Clifton-downs, and she stood near the edge and remarked it would be a fine opportunity for her to jump over the rocks. She has applied to me for help, but not lately. She has said that she would not trouble me long.

Mr. PESTER said Miss Salmon had behaved herself very properly while she had been with him.

Dr. HERAPATH remarked that the deceased, in his opinion, suffered from impulsive insanity.

Mr. WASBROUGH then summed up, directing the attention of the jury to the various points in the evidence, and he pointed out to them that the questions for their consideration were, whether the deceased took the oxalic acid, and whether, at the time she committed the act of self-destruction, she was in a sane state of mind and was responsible for her acts.

The jury returned a verdict of "Temporary Insanity."

INHALATION IN DISEASES OF THE LUNGS AND AIR-PASSAGES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It must be admitted that the several affections of the respiratory organs constitute the largest class of maladies in this country, and that phthisis and bronchitis contribute the greatest proportion to the records of mortality. The latter diseases may indeed be emphatically called the scourges of this climate. The tables of Young, Woolcombe, Clark, Williams, and the more recent and admirable compilations of the Registrar-General, demonstrate that not less than one-fifth part of the adult population, and a still larger proportion of children, die from pulmonary consumption. When to this we add the deaths from bronchitis, asthma, and other forms of disease having their seat in the air-passages and lungs, the sacrifice of life caused by these ailments may be fairly estimated to amount to nearly one-third of the gross mortality.

The ingenuity of many minds has been successfully exercised in designing, and has resulted in the production of a variety of effective instruments, by which medicines can be administered, through the medium of the respiration, in the form of gas or vapour, or in solution reduced to a minute state of subdivision by mechanical force, and presented as a fine spray. England, France, and Germany, are equally represented in this field of scientific enterprise, while the pharmacopœia and laboratory are being daily rendered more fruitful of remedial agents.

The points to which I would chiefly direct attention for the consideration of those who desire to investigate the subject, are—

1st. That medicines when inhaled act locally on the air-passages and cells, and it is only when so administered that any direct action can be produced by them analogous to that which is effected by their application to other portions of the body.

2nd. That inhaled medicines do act constitutionally as well as locally, and they do this more promptly, more powerfully, and with less disturbance of the other organic functions than when administered through the medium of the stomach. A partial exception, under this head, may be made in favour of the plan of hypodermic injection in as far as regards rapidity and intensity of action, but the functional disturbance arising from this latter mode is frequently very severe.

3rd. That the treatment by inhalation is based upon scientific principles, and its safety and soundness in practice is susceptible of demonstration from facts recorded by the highest authorities in our profession, while its elegance, ease of administration, and freedom from all that is objectionable in the taste, odour, and other qualities which make medicines, when

swallowed, very repugnant to most patients, are unquestionable.

4th. That besides being a most reliable curative means when employed alone, it is also a most valuable adjunct to stomachic medication in cases of disturbed organic function which demand treatment through the medium of the digestive organs.

5th. That, as a system of practice, the method of administering medicines by inhalation is as complicated, and requires as much judgment and experience for its employment, as the administration of medicines by the stomach. The selection of the remedies to be used must be based on the fundamental principles of pharmacology, and the practitioner must be guided in the construction of his formulæ, by the experience acquired by him of their action under various circumstances in different individuals, and for the several diseases.

6th. That it is a system of treatment worthy of the fullest investigation by physicians, as curators of the public health, for their judgment in the matter becomes a question in which the public may truly be said to have the interest of life itself, and by an impartial test of its merits only can it be saved from becoming prejudiced in the estimation of the world.

Full and free discussion on these various points can only be productive of good, and I have been influenced in thus writing with a desire to evoke such discussion through the medium of your valuable journal.—I am, Sir, obediently yours

ROBERT GEORGE WATTS, M.D.

THE APPLICATION OF THE SPINAL ICE-BAG IN THE TREATMENT OF DELIRIUM TREMENS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to a statement made by Dr. Hewitt during the debate upon Dr. Chapman's spinal ice-bag, at the last meeting of the Surgical Society, to the effect that he was the first physician to apply it in the treatment of delirium tremens, I wish to inform you that last November I had recourse to it for the purpose of checking violent and persistent vomiting in a case of extreme nervous perturbation, *bordering closely* upon delirium tremens, the result of a prolonged debauch. Before employing the bag I tried the following remedies without in the least degree influencing the vomiting—viz., hydrocyanic acid in solution of magnesia, mist. creosoti., morphia, chloroform, chlorodyne; brandy and ice internally; dry-cupping sinapisms, and the application of a liniment consisting of equal parts of lin. aconiti and lin. chloroformi, over the region of the stomach and liver. After the bag had been a very short time applied, the retching ceased, and returned only once during his illness, which lasted three or four days.—I am, Sir, yours very truly,

N. J. BUTLER, L.C.P.I., &c.

UPHOLDING THE CAUSE OF POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Give me space to express twofold gratitude—firstly, to Dr. H. W. Williams, who has spoken so boldly in your issue of April 22; secondly, to you as the Editor of THE MEDICAL PRESS AND CIRCULAR, for the articles you have during the last year devoted to our cause, not the least important of which is the one that has called for the letter of Dr. Williams. Sir, you deserve double thanks, because when others have grown lukewarm or faithless in our cause, you have taken it up with greater earnestness and greater power than ever. It is no secret, sir, that the last year or two has witnessed astounding changes in professional journalism—most of all in THE MEDICAL PRESS AND CIRCULAR. You seem to have got rid of all namby-pambyism, and to have adopted the most manly, outspoken, and independent tone. The Poor-law Medical Officers will henceforth know where to look. This last point you have taken up (the medical inspectors and what is expected of them), none of your contemporaries have dared to touch. I know they have been urged to mention it, but dare not or will not. The power of cliquism with some, the hope of windfalls with others, keeps them from what they consider dangerous ground. Meanwhile, Poor-law doctors lose faith in the sincerity of their *quondam* friends, or their hopes for the future grow feebler day by day. You, sir, have caused an electric shock to run through the whole body, and with such a helping hand as you have lately extended to us, I for one take heart again. Long may THE MEDICAL PRESS AND CIRCULAR retain the confidence it has so justly won. On every occasion I shall point out to non-subscribers the honesty of its advocacy of the rights of the profession, and my conviction that the editorial department in the last few months has been improved in a degree no one could have anticipated.—I am, &c.,

A POOR-LAW DOCTOR.

MERCURIALISTS AND ANTI-MERCURIALISTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Anything bearing on the above subject must be interesting to your readers in general. Therefore, allow me to record the following case which came lately under my observation:—

A farmer, aged 43, sent for me on 6th of February last, and I found him suffering from acute pleuritis. As he appeared to be possessed of a sound constitution, and was not run down by the disease (though the latter was of a very sthenic type), I resolved to give mercury a fair trial, and ordered minute doses of calomel, with directions to stop them the moment the mouth became affected. On the second day very slight salivation ensued, and immediately the urgent symptoms of the disease abated, and in a very few days all signs of the original pleuritis had disappeared. But scarce a week of convalescence had elapsed, when another evil stared us in the face: erysipelas set in; both arms and right leg were attacked. A large diffuse abscess formed below the knee, another above the elbow, and for many weeks I had little hope of my patient's recovery. However, under tonic treatment he has now made a tolerable recovery. I think this case interesting, because, in the first place, it tends to prove that mercury has the power of arresting inflammation; and, secondly, it shows that the very process by which it accomplished this, viz.—by its solvent action on the blood, is in many cases highly prejudicial.

If both mercurialists and anti-mercurialists would carefully weigh the facts of a case like this, I think that neither party would be so dogmatic in their opinions as they seem to be.—I remain, sir, your obedient servant,

Bantry, May 1, 1868. A. B., M.D., M.Ch.

Medical News.

ROYAL INSTITUTION OF GREAT BRITAIN.—The following gentlemen were unanimously elected as officers for the ensuing year, at the late annual meeting:—

PRESIDENT—Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.
TREASURER—William Spottiswoode, Esq., M.A., F.R.S.
SECRETARY—Henry Bence Jones, M.A., M.D., F.R.S.
MANAGERS—Henry Wollaston Blake, Esq., M.A., F.R.S.; Charles Brooke, Esq., M.A., F.R.S.; Adm. Sir Henry John Codrington, K.C.B.; Captain Douglas Galton, C.B., F.R.S.; John Peter Gassiot, Esq., F.R.S.; William Robert Grove, Esq., M.A., Q.C., F.R.S.; Cæsar H. Hawkins, Esq., F.R.S.; Sir John Lubbock, Bart., F.R.S. Pres. Entom. Soc.; Sir Roderick I. Murchison, Bart., K.C.B., D.C.L., F.R.S.; William Pole, Esq., M.A., F.R.S.; William Frederick Pollock, Esq., M.A.; Robert P. Roupell, Esq., M.A., Q.C.; Lieut.-Gen. Edward Sabine, R.A., D.C.L., Pres. R. S.; Sir Charles Wheatstone, D.C.L., F.R.S.; Colonel Philip James Yorke, F.R.S.
VISITORS—Andrew Whyte Barclay, M.D.; Charles Beevor, Esq., F.R.C.S.; John Ashton Bostock, Esq.; John Charles Burgoyne, Esq.; Rev. Charles Fynes Clinton, M.A., F.R.G.S.; Alfred Davis, Esq.; William Dell, Esq.; Rev. G. Godwin Pownall Glossop, A.M.; Alfred Gutteres Henriques, Esq.; Edward Henry Moscrop, Esq.; William Newmarch, Esq., F.R.S.; Arthur Giles Puller, Esq., M.A., F.S.A.; Samuel Scott, Esq.; Edward Owen Tudor, Esq., F.S.A.; Robert Ballard Woodd, Esq., F.S.A., F.R.B.S.

Drs. Tyndall and Frankland were re-elected Professors of Natural Philosophy and of Chemistry.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were admitted Members of the College by Diploma on the 5th and 6th inst.:—

John Adams, Shelton; W. P. Adams, Rochester; J. P. Anderton, Manchester; H. A. Bale, Exeter; J. A. P. Banks, Acton; W. C. Barmish, Wigan; John Bately, Great Yarmouth; Fletcher Beach, Bredport; William Bishop, Chipping Norton; J. W. Blandford, Corbridge; H. W. Boddy, Manchester; C. T. Brookhouse, Nottingham; Andrew Boulflower, Manchester; W. P. Bridges, Cirencester; J. A. T. Cartwright, Spalding; T. E. Clark, Kirby Lonsdale; C. H. J. De la Fertè, Porchester-terrace; T. W. W. Fay, Liverpool; Richard Fletcher, Bury, Lancashire; J. H. Forte, Brabadoes; J. H. Gay, Wisbeach; J. A. Giddings, Old Trafford; Walter Hart, Pimlico; R. M. Jones, Groes, Denbigh; Frederick Morgan, Taunton; J. R. Morgan, Merthyr Tydfil; S. J. Noake, Leeds; Frederick Page, Southsea; J. W. Paton, Ayr; George Payne, Wallingford; Wilton Provis, Bath; C. J. Rix, Manchester; Owen Roberts, Pwllheli; W. L. Roberts, Spitsby; Robert Robertson, Fowey; J. R. Rouch, Bristol; Pharoz Shore, Walsall; J. P. Sleightholme, Whitby; T. A. Somerville, Wilmslow; A. E. Sutcliffe, Scarborough; J. A. Thompson, Delamere-

street; John Tuck, Ilford; J. E. Ward, New Kent-road; W. J. C. Ward, Devonport; J. L. Williams, Wrexham; Owen Williams, Anglesea.

And on the 7th inst.:—Messrs. G. R. Nunn, Lyndhurst, Hants, and Jacob French, Deptford, students of Guy's Hospital; W. H. Drew, Gower-street, Bedford-square, of University College; R. B. Gilland, M.D. Glasgow, and L.S.A. Brentwood, of the Glasgow School; J. W. Pratt, L.S.A. Bradford, Yorkshire, of St. Mary's Hospital; and Ferdinand Beadles, Broadway, Worcestershire, of the Westminster Hospital. It is stated that only five out of the 57 candidates examined for the diploma of membership failed to acquit themselves to the satisfaction of the Court of Examiners, and were consequently referred to their hospital studies for the period of six months.

UNIVERSITY OF EDINBURGH.—We understand that an offer of £3000 has been made as an endowment for a special chair of Applied Mental Science, on condition that from £1500 to £2000 shall be supplied from other sources. Such a chair would render the University complete in every department of Mental Science, and would lead to most valuable practical results.—*Edinburgh Courant.*

ROYAL COLLEGE OF SURGEONS IN IRELAND.—A meeting of the Fellows was held on Tuesday, the 5th of May, at three o'clock, pursuant to the provisions of the Supplemental Charter, to witness the election of seven examiners to examine candidates for fellowship and letters testimonial, when the following gentlemen were elected, viz.:—John Barker, Maurice H. Collis, Christopher Fleming, Edward S. O'Grady, Benjamin W. Richardson, Edward A. Stoker, and Jolliffe T. Tufnell; three examiners to examine candidates for the diploma in midwifery, when the following gentlemen were elected, viz.:—John Cronin, James Isdell, and Edward J. Quinan; and three examiners to examine students as to their proficiency in general education, when the following gentlemen were elected, viz.:—Thos. Byrne, John Murray, and George F. Shaw.

THE FIRST SUMMONS UNDER THE NEW WORKSHOPS' REGULATIONS ACT.—Dr. Aldis, officer of health for St. George's, Hanover-square, has just done good service to the commonwealth by taking out two summonses against Miss Eleanor Salmon, dressmaker, of No. 49A, New Bond-street, for employing young women beyond the stipulated number of hours named in the Workshops' Regulations Act. The case was heard at Marlborough-street before Mr. Tyrwhitt, and Mr. Redgrave, the chief inspector of factories, was present. Any unpleasant revelations which might have been made were nipped in the bud by Miss Salmon's pleading guilty, expressing her sorrow for having unwillingly contravened the statute, and stating in excuse that she had had a "heavy mourning order on hand." Exactly so; it is precisely when the "heavy orders" are "on hand" that the poor milliners and dressmakers are worked nearly to death's door; and it was to prevent their immolation on the altar of fashion and vanity, shrieking out their "heavy orders" that this Act of Parliament was passed. To-day is the 1st of May, and the London season may be said to have fairly commenced. Nobody supposes that Miss Salmon would overwork her "hands," if she had nothing to do; but during the next four months she will, doubtless, be inundated with "heavy orders" for horticultural fetes, Crystal Palace concerts, balls, picnics, archery meetings, Ascot Cup days, and other "functions" of Vanity Fair. Miss Salmon having owned her culpability, and the officer of health having no wish to press for a penalty in the first case under the Act, Mr. Tyrwhitt discharged the defendant on payment of the costs; but he hinted that in future the Act must be more rigidly enforced; and Dr. Aldis, we are sure, will not falter in his labours. We have heard a good deal of Bethnal-green lately; but it behoves us to remember that there are Londoners within as well as "over the border," who, if we are remiss in exposing their grievances, may suffer as acutely in the palatial parish of St. George's as the wretchedest drudges suffer in the most pauperised districts of this metropolis.—*Telegraph.*

THE MOTHER AT HOME *v.* PUBLIC NURSERIES.—A writer in the *Queen* remarks on this subject, that while commending the good intentions of the promoters of Infant Day Nurseries, it cannot but be regretted that the efforts of those benevolent persons are not more wisely directed. Similar undertakings have failed over and over again, and they will continue to fail, because—apart from the question of management—the idea, however well meant, has arisen out of a wrong state of things, and is based upon an erroneous principle. The "infant day nursery," in fact, is a clumsy attempt to supply the place of the mother; and as those mothers who—from a short-sighted and mistaken policy—leave their families in order to earn a few daily pence, violate one of Nature's laws, the result *must* be disastrous to the infant population. It is true that the children who are sent to the "day nursery" may escape some of the dangers which threaten to overtake them if left at home while the mother is out at work; but nothing can compensate for the absence of the wife and mother from her home, notwithstanding what political economists may have to say upon the subject.

VITAL STATISTICS OF THE COUNTRIES OF EUROPE.—From a report just laid on the table of the House of Commons the following particulars have been selected:—"In France the marriages, which had declined from 305,203 in 1861 to 298,838 in 1865, rose in 1866 to 301,390; but the births, which numbered 994,288 in 1866, were 12,465 less than the number in 1865. To 100,000 of the population in France in 1866 there were 1584 persons married, while the proportional number in England was 1770; and to 100,000 of population in either country, the number of births was 2612 in France, and 3554 in England. Taking the interval between the mean age of the mothers at marriage and their mean age at the birth of their children at six years, then the number of legitimate births to a marriage in 1866 was 3·1 in France and 4·2 in England. The death-rate in France in 1866 was 23·26 per 1000 of population; that of England being 23·61. The population of the kingdom of Italy in 1866, exclusive of Venetia, was 22,703,135; the death and birth rates respectively were 28·96 and 38·62 per 1000 of population. Spain, with an estimated population in 1866 of 16,516,949, returned a death rate of 28·05 per 1000, and a birth rate of 37·03 per 1000. The results for the Austrian Empire, exclusive of the states of Italy, show a population in 1866 of 37,929,918, the respective death and birth rates were 32·32 and 40·34 per 1000 persons living; the marriage rate was low, 14·58 persons married to 1000 of population; but it will be remembered that 1866 was the year when disaster befell the arms of that empire. Thus, the returns of Austria show a birth rate much higher than the English rate, and conspicuously higher than the French rate. The birth rates of Italy and Spain are both higher than the English rate, and show a superiority only too striking over that of France. The death rate of Austria is considerably higher than the rates of England and France, and the death rates of Spain and the Italian kingdom contrast unfavourably with those of England and France."

APPOINTMENTS.

GAVIN, M. F., M.D., L.R.C.S.I., has been appointed successor to Dr. Ropes, as Surgeon to Out-patients' City Hospital, Boston, U.S.

MADDEN, THOMAS MORE, M.R.I.A., L.K.Q., & K.C.P.I., M.R.C.S.Eng., has been appointed Assistant-Physician to the Dublin Lying-in Hospital, Rotundo.

MORGAN, Mr., A.M., T.C.D., F.R.C.S.I., Professor of Practical Anatomy, R.C.S.I., &c., has been appointed Surgeon to the Westmoreland Lock Hospital.

BYRNE, Dr., has been appointed Consulting-Surgeon to the Westmoreland Lock Hospital.

NOTICES TO CORRESPONDENTS.

Gentlemen whose subscriptions are behind, are requested to send cheque or P. O. O. without further delay.

In consequence of the pressure on our space, several articles and letters are again held over.

Several subscribers have inquired about the Diary and Notices of the Week, as well as Notices to Correspondents. We beg to say they are only omitted on account of the press of other more important matter. We are obliged frequently to leave out Notices to Correspondents that would perhaps be interesting to many, and reply privately for various reasons.

The following resolution, which has been forwarded to John Brady, Esq., M.P., is sent us by a correspondent for publication:—

RESOLVED—That we, the Members of the Northern Medical Society of Liverpool, having had our attention drawn to certain recent cases, wherein certificates of death had been obtained by persons interested in such deaths, while the individuals to whom the certificates referred were *actually living*, beg to call the attention of the legislature to the form of certificate (herewith enclosed), as now supplied to Medical Practitioners.

That, while anxious to supply to the Registrar all the scientific information in our power as to the probable cause of death in any case where we may have been in attendance, we respectfully submit that we should not be asked to certify to the age, "last birth-day," or to the fact "that he died on ," inasmuch as such information is in all cases supplied to us by the person applying for the certificate. That it would tend materially to prevent fraud and oppose a serious barrier to the

Dr. LETHEBY'S FOURTH LECTURE ON FOOD.

PRESERVATION OF FOOD.—UNWHOLESOME AND ADULTERATED FOOD.

(Continued from page 416.)

The flesh of animals that have been excited before death, as by over-driving, or by torture, has frequently proved unwholesome. A remarkable instance of this is quoted by Liebig in his Letters on Chemistry, where a family of five persons were made seriously ill by the flesh of a roebuck which had been caught in a snare and had struggled violently before death.

It is, moreover, a curious fact, that meat may be even poisonous from the nature of the food made use of by animals shortly before they are killed; and this, too, without any indication of disorder in the animals themselves. Hares which have fed upon the *Rhododendron chrysanthemum* are frequently poisonous; the same is the case with pheasants in Pennsylvania and Philadelphia which feed during winter and spring on the buds of the laurel *(calmia latifolia)*; and I have known many instances of serious mischief from Prairie birds, which are now largely imported into this country from America, and I attribute it to the food made use of by the bird. In certain districts of North America, especially on the Alleghany mountains, the flesh of all the cattle is poisonous, and so also is the milk they yield, and the cheese which is made from it. Oysters, mussels, lobsters, and crabs have frequently caused disturbance of the human system; and the probability is that they were made unwholesome by the food which they had eaten. A singular case is recorded in the medical journals of France in 1842, where a whole family at Toulouse were poisoned by a dish of snails, the animals having been gathered from a poisonous shrub *(Coriaria myrtifolia)*; and it is not at all uncommon for honey to be unwholesome, on account of its having been collected by the bees from poisonous plants. The honey of Trebezond, for example, has long been notorious for its deleterious properties; it poisoned the soldiers of Xenophon during the famous retreat of the ten thousand. Pliny, too, speaks of it; and to this day its intoxicating effect is frequently witnessed. It arises, no doubt, from the plants, chiefly the *Azalea pontica*, from which the honey is gathered. Mr. Barton has given us a similar account of the poisonous quality of the honey gathered by the bees from the savannahs of New Jersey, where the *calmia* and *azalea* were the principal flowering shrubs. As with the followers of Xenophon, all who ate of the honey became intoxicated to a high degree; even when made into metheglin, it poisoned all who partook of it, causing dimness of sight, giddiness, and then delirium, with sometimes a fatal termination.

Occasionally we have examples of food which is in itself poisonous. This is so with many of the fish of tropical seas, and especially of the West Indies. Dr. Burrows has given us a long list of them; and it would seem that the yellow-billed sprat (the Sardine doré of the French and *clupea thryssa* of naturalists), the toad, or bladder-fish *(aplodactylus punctatus* or *Tetraodon* of Cuvier) and the gray-snapper *(coracinus fuscus major)* are the most venomous; and that, being eaten by larger fish, as the *Baracosta*, and various species of perch, as well as the conger-eel, the dolphin, the globe fish, &c., it causes these to be poisonous also. The yellow-billed sprat is so virulent in its action on the human body that both Europeans and negroes have been known to expire with the fish in their mouths unswallowed; and the toad, or bladder-fish, is scarcely less dangerous. Sir John Richardson has described the effects of it on two sailors, the boatswain's mate, and purser's steward, of the Dutch brig of war, *Postilion*, while lying at anchor in Simons Bay, at the Cape of Good Hope in September, 1845. The men were warned that the fish was poisonous, but believing that the liver was wholesome and rather a delicacy, they cooked it, and ate it directly after their twelve o'clock dinner. In ten minutes the boatswain's mate was so ill that he could not stand; his face was flushed, his eyes glistened, his lips were swollen and rather blue, his forehead was covered with a cold perspiration, and his pulse was weak and fluttering. He was, however, quite conscious, and complained of pain and constriction of the throat; and he had a desire to vomit. In a few minutes more he became paralysed, his eyes were fixed, his breathing was laborious, his face was pale, though his lips were livid, and in seventeen minutes he was dead. The other man exhibited the same symptoms, and died in twenty minutes. Sir John Richardson says, the fish was not more than six or eight inches in

length, and the liver of it which they had eaten between them, could not have weighed more than half an ounce.

The symptoms occasioned by the poisonous fish of the tropics are always of two kinds: there is either great irritation of the stomach and bowels, like cholera; or there is rapid prostration of the vital powers, and death by syncope or convulsions. These effects have been long known to both natives and Europeans, and were called by the Spanish colonists of Tropical America, *Siquatera*. They are more frequently observed at certain seasons of the year than at others, and hence, they are thought to be due to certain physiological changes in the body of the fish, or to the food which it has eaten. In some cases the roe, in others the liver, or the digestive organs are the most poisonous parts of the fish; and in the case of the *maletta venenosa*, which inhabits the Caribbean sea, it is only poisonous when the sea is covered with a green monad upon which the creature feeds. Happily for us, these dangers are confined to the tropics, although we sometimes suffer from a milder form of disturbance, as irritation of the skin and bowels, from eating unwholesome shell-fish.

Putrid meat is, perhaps, wasteful, rather than actually injurious; but there are plenty of cases in which it has caused disease. Foderé tells us that at the seige of Mantua, those who were shut up in the city, and were obliged to eat the half-putrid flesh of horses, suffered from gangrene and scurvy; and in Czant's history of Greenland there is an account of the death of thirty-two persons at a missionary station called Kangek from a repast on the putrid brains of a walrus. Similar cases are recorded in all the books on legal medicine. Even game, when only sufficiently tainted to please the palate of the epicure, has caused severe cholera in persons unaccustomed to it; but as Dr. Christison observes, "the power of habit in reconciling the stomach to the digestion of decayed meat is inconceivable. Some epicures in civilised countries prefer a slight taint even in their beef and mutton: and there are tribes of savages still further advanced in the cultivation of this department of gastronomy, who eat with impunity rancid oil, putrid blubber, and stinking offal." The Zulus of Natal, according to Dr. Colenso, are so fond of putrid meat that they call it *ubomi*, which literally means to be superlatively happy. But, as a rule, there is a natural abhorrence of tainted food, insomuch, that with most persons, the mere commencement of decay is sufficient to excite disgust; and rarely do we find, except among savages, that an entire meal is made of putrid flesh. A little game or venison, or ripe cheese, at the end of a feast, with just a piquant touch of decay, is perhaps not objectionable; for it may, as Liebig supposes, promote digestion, by communicating its own quality of transformation to the rest of the food; but it is another thing to fill the stomach with putrid flesh, for if the corrective power of the gastric juice should fail, the effect of it might be serious. We have, indeed, abundant evidence of the terrible consequences of admitting putrid matter into the circulation, for they were once too common among those engaged in the dissection of the human body. In fact, the mere handling of decomposing animal matter for any time, will often produce disease of the hands or other parts of the body with which it comes into contact. Our safety, perhaps, in using such food, is in the antiseptic power of good cooking, but this is not always an easy affair; for the tissues are generally so soft from decay, that they will hardly bear the common action of heat; so that if they be boiled for any time, they will fall to pieces; and if they be roasted, they will shrink without forming that delicious crust of osmazome which is characteristic of good meat. Let them, however, be cooked as they may, they always require a nice adjustment of rather strong flavours to make them palatable; and those who have dined in the cheap restaurants of Paris, or at the still worse table d'Hote of a German watering-place, will have experienced the art of the cook in this respect, in such dishes as *turbot en vol-au-vent, Raie au beurre noir, sole en matelote Normande*, and in the various forms of fish, *au gratin*; or game, *en salmis*.

But bad as this sort of tainted food is, it is nothing in comparison to the sausage poison, which is produced by a sort of modified putrefaction to which the large sausages of Germany, and especially those of Würtemburg, are occasionally subject. According to an official return there have been more than 400 cases of poisoning from these sausages in Würtemberg alone during the last fifty years, and of these about 150 were fatal. The effects are generally observed in spring, and mostly in April, when the sausages become musty, and acquire a soft consistence in the interior. They have also a peculiarly nauseous and rather putrid taste, and are very acid to test-paper. If eaten in this condition, they produce dangerous effects in from twelve to twenty-four hours — the first symptoms being pain in the stomach, with vomiting and diarrhœa, and dryness of the nose and mouth; then comes a feeling of profound depression, with coldness of the limbs, weakness and irregularity of the pulse, and frequent fainting. Fatal cases end with convulsions, and oppressed breathing between the third and eighth day. The precise cause of these effects is still a mystery; some have thought that rancid fatty acids are produced during the decomposition of the meat; others that in the process of drying and smoking, acrid pyrogenous acids have been developed; others that during the decay of the sausages, a poisonous organic alkaloid is generated. Liebig is of opinion that the effects are due to an animal ferment, which produces in the blood, by catalysis, a state of putridity analogous to its own, and that the molecular movements of the putrefactive change in the decaying meat are thus communicated to the living organism. M. Vanden Corput, who is one of the most recent investigators of the subject, attributes the morbific action of such meat to the presence of a minute fungus of the nature of a sarcina, which he calls *sarcina botulina*. This view is confirmed by the fact that there is always a peculiar mouldiness of the sausages; and the poisonous property is generally observed in April, when these cryptogamic organisms are most freely developed.

Similar effects have occasionally been produced by other kinds of animal food—as veal, bacon, ham, salt-beef, salt-fish, cheese, &c., and the food has usually been in a decayed and mouldy condition. It would be tedious if I were to detail, or even to enumerate the cases recorded by medico-legal writers; but I may, perhaps, refer with advantage to a few of them. In 1839, there was a popular fete at Zurich, and about 600 persons partook of a repast of cold roast veal and ham. In a few hours most of them were suffering from pain in the stomach, with vomiting and diarrhœa, and before a week had elapsed, nearly all of them were seriously ill in bed. They complained of shivering, giddiness, headache, and burning fever. In a few cases there was delirium; and when they terminated fatally, there was extreme prostration of the vital powers. Careful inquiry was instituted into the matter, and the only discoverable cause of the mischief was incipient putrefaction and slight mouldiness of the meat. Dr. Geiseler relates an instance where a family of eight persons were made ill by musty bacon; and M. Ollivier has given an account of six persons who were poisoned by mutton in a state of modified decay—four of whom died from it within eight days. In Russia, where it is the practice to eat largely of salt-fish, in a raw condition, it is not at all uncommon to witness the dangerous effects of it, when it has become mouldy or putrid; and in fact it is within the experience of every one who is concerned in medico-legal inquiries, that serious symptoms are frequently traced to the use of food in a modified condition of decay. This is especially so with bad cheese, the effects of which on the constitution have been so severe, that official investigations have been called for. These effects have been noticed at Schwerin (1823), at Minden (1825), at Hameln (1826), at Greifswald (1827), Frankfort (1828), and elsewhere; and they have been the subjects of interesting essays by Henneman, Hünefeld, Westrumb, and others. At first the effects were attributed to the copper-vessels used in the dairies, and therefore the

Austrian, Wirtemberg, and Ratesberg States prohibited the use of that metal for such purposes; but the subsequent inquiries of Hünefeld, Sertürner, and other chemists, established the fact that no metallic poison was discoverable in the cheese. In the Police Report, which was published in Frankfort, in January, 1828, informing the public of numerous cases of poisoning in that city from spoiled cheese, it was declared that no poisonous principle could be detected by chemical re-agents. Professor Hünefeld, and subsequently Sertürner, were of opinion that the effects were due to certain poisonous fatty acids, analogous to, if not identical with, caseic and sebacic acids; and they even describe the way in which they are produced in the cheese during the process of ripening—attributing them to the imperfect removal of the acid liquor from the curd when the cheese was made, or to the putrefaction of the curd before it was salted, or to the mixture of flour with the curd; but it is far more likely that the poisonous effects are due, as Vanden Corput supposes, to the presence of a peculiar mould or fungus. I have myself seen the most terrible consequences from the use of such cheese, and have failed to discover anything unusual in the acidity or other chemical reactions of the cheese. Hünefeld says, it is commonly a yellowish-red, soft and tough, with harder and darker lumps interspersed throughout it, and that it has a disagreeable taste, and an acid reaction. The symptoms which it produces are very much like those of sausage poisoning—namely, irritation of the stomach and bowels, with great prostration of the vital powers. These effects have been witnessed not only in Germany, where the cheese are generally rancid and bad, but also in this country, and particularly among the small hill-farms of Cheshire, where the limited extent of the dairies obliges the farmer to keep the curd for several days before a sufficient quantity of it is accumulated to make a large cheese.

I have said nothing of the improper practice of killing very young animals, especially calves, for food, before the tissues have had time to change from their uterine condition. On the continent it is unlawful to kill or to sell calves for food that are not more than fourteen days old, but in this country there is no such restriction, and it is a common practice to dispose of the carcasses of newly-born, or even fœtal calves, to the sausage-maker; and as the flesh is sodden and insipid, he strengthens it with old, tough, and sinewy flesh. It has the advantage, moreover, of being miscible with any description of meat, and of taking any variety of flavour; in fact, it makes just that kind of sausage which is susceptible of any kind of flavour, and where, to use the expression of Dickens, "it's the seasonen as does it." I cannot say that such meat is positively unwholesome, but it is nasty, and excites the same sort of disgust as an egg with a chick in it.

As regards vegetable foods, they are not so liable to decay or even to parasitic infection, as animal foods; for the acori or mites of flour and sugar, or even the weevels of biscuit are harmless; indeed, the most important infection of grain is the fungoid disease of it, called *ergot*. This is the *muttercorn* or *roggenmutter* of the Germans, and as it chiefly infests the rye, it is named, from its appearance, *spurred-rye;* but it also attacks barley, oats, wheat, maize, rice, and most of the grasses. It always appears as a black grain, of a larger size than usual, and it is mostly found in plants which grow upon moist clay soils, in damp situations, especially in the neighbourhood of forests. The district of Sologne in France, between the rivers Loire and Cher, was once notoriously infested with the disease, and the Abbé Fessier, who was deputed in 1777 to investigate the causes of the extraordinary prevalence of ergot in that district attributed it to the poorness and wetness of the land, and to the dampness of the air from the numerous forests. In bad seasons, as much as a-third or a-fourth of the crop was infected with ergot, and even in good seasons it constituted about 2 per cent. of it. The disease in the grain is due to the growth of a peculiar fungus, which the late Mr. Queckett named *ergotetia abortifaciens;* and the effects of it on the human body are very serious. It acts chiefly on the nervous system, causing giddiness, dimness of sight, loss of feeling, and twitching of the limbs, and death by convulsions; or it produces a creeping sensation over the surface of the body, with coldness of the extremities, followed by insensibility and gangrene. These effects are no doubt referred to by Ligebert in his History of Gaul and France, when he says that the year 1089 was a pestilent year, especially in the western parts of Lorraine, for many persons became putrid in consequence of their inward parts being consumed by St. Anthony's fire. Their limbs were rotten, and became black like coal, and they either perished miserably, or, being deprived of their putrid hands and feet, were reserved for a more miserable life. Bayle, too, in his account of this sickness says, that the bread was of a deep violet colour. The like effects have been observed in other parts of the continent, as in Silesia, Prussia, Bohemia, Saxony, Holstein, Denmark, Switzerland, Lombardy, and Sweden, where the creeping sickness, as it is called, has attacked whole districts of the country, sparing neither old nor young, nor rich nor poor.

The remedy for the disease is in the hands of the miller, who should separate the ergotised from the healthy grains. Fortunately we have a ready test for its presence, not merely in the microscopic appearances of the flour, but in the circumstance that as it is the lightest of all the constituents of flour, it will float upon a mixture of 1 part of chloroform and 6 of alcohol, and will appear as a scum of dark brown particles.

Another source of danger is the presence of the ground seeds of poisonous grasses in the flour. The most important of these is darnel (*lolium temulentum*), which the careless or slovenly farmer will sometimes permit to overrun his fields, and the seeds becoming mixed with the corn, are ground into flour by the equally careless miller. The effect of the grains on man, is to cause a species of intoxication, with headache, giddiness, somnolency, delirium, convulsions, paralysis, and even death. Occasionally it excites vomiting, with irritation of the alimentary canal, and then its effects are not so serious. Many instances are recorded of the poisonous action of the flour. Christison, for example, tells us, that a few years ago almost all the inmates of the poor-house at Sheffield, to the number of 80, were attacked with analogous symptoms, after breakfasting on oatmeal porridge, and it was supposed that the effects were caused by the presence of darnel in the oatmeal. A similar accident is mentioned by Perleb as having occurred at the House of Correction at Freyburg, and still more recently the same effects were produced on 74 persons at the workhouse of Beninghansen. Dr. Taylor states, on the authority of Dr. Kingsley, of Roscrea, that in the month of January, 1854, several families, including about 30 persons, suffered severely from the effects of bread containing the flour of darnel seeds. Those who partook of the bread staggered about as if they were intoxicated, and although they all recovered, yet they experienced a good deal of distress from giddiness, coldness of the limbs, and great prostration of vital power.

Unripe grain, as well as grain affected with the *rust*, and *mouldy flour* and *mouldy bread*, have also produced disturbance of the human system. M. Bouvier attributed the epidemic of dysentery, which occurred in the department of the Oise, in the autumn of 1793, to the use of *unripe grain;* and corn affected with *brown* or *black rust* is thought by many to be unwholesome. *Mouldy flour* or *mouldy bread* is certainly injurious, for several instances are on record where not only man, but horses, have been poisoned by mouldy bread; and M. Payen has given a graphic account of the distressing effects of the mouldy ammunition-bread supplied to the troops who were encamped near Paris in 1843; the mould on that occasion was a yellow fungus, the *oidium aurantiacum*, but at other times it has been of a green colour, from *pennicillum glaucum*.

Mouldy food of every description is dangerous to use, and considering to what an extent the *spores* or *sporidia* of

poisonous fungi are floating in the atmosphere, it is surprising that they do not more frequently taint our food and cause disorder of the system, for air washed with distilled water will always yield abundance of these germs, which are ready at any moment to spring into activity, when they come into contact with a proper nidus for their growth. As in nearly all the cases to which I have referred the remedy for these hidden sources of danger is good and effective cooking.

(To be continued.)

Original Communication.

THE RATIONAL TREATMENT OF CONSUMPTION.

By JOHN MULVANY, M.D., L.R.C.S.Ed., Etc.,
ASSISTANT-SURGEON, R.N.

(Continued from page 418.—Conclusion.)

TREATMENT.

HAVING shown that a deficiency of oxygen in the blood is the "fons et origo mali" of tuberculosis in its first stage, the treatment will naturally consist in remedying the chemical errors which have resulted from it. The patient must be instantly removed, to a healthy atmosphere, daily corporeal ablutions must be prescribed, gentle exercise must be ordered. Pettenkofer and Vogt having shown that the elimination of carbonic acid is thereby increased, oxygen must be added to the blood. Permang. potassæ probably offers the best vehicle for it, containing, as it does, two or three atoms in its allotropic or most active state. When the acidity and dyspeptic symptoms have been removed, the patient may be put on a liberal diet, with a bottle of porter daily, and cod-liver oil. I select the following case in illustration of the efficacy of the above treatment.

Thomas Hacklin, æt. 28, a labourer, residing a few miles from Haldimand, on the Port Dover-road, applied to me, August 28th, because all his money was spent on medical advice ashore, and begged me to try and do something for nim ; he was accompanied by his stepmother aud brother, and from them I got the following history of his case :—His father, mother, and other relatives died of consumption, he has had a cough for a year and a half or two years, this latterly has become much worse, occurring in paroxysms, which when of unusual severity give rise to epileptic fits. He has had these fits since the commencement of the year (eight months.) They occurred at first at longer intervals, but now recur two or three times a week ; and according to his mother-in-law and brother's statement are very severe, and generally followed by a state of maniacal excitement, during which he would smash the chairs, tables, crockery, &c., or run mad into the woods. They were consequently obliged to keep him always in view.

His appetite was bad ; his tongue looked swollen and flabby ; his gums had a ragged appearance, attached to the sides of the teeth ; they had receded from the anterior aspect of their necks almost up to the alveoli, giving them a formidably long appearance ; he had long been losing flesh ; suffered from chills, palpitations, sweats, &c. ; his pulse was 89 ; respirations 19 ; temperature 100°3 ; heart's action a little irregular ; has but little expectoration, which has been several times bloody ; beneath the right clavicle there was dulness on percussion ; a crackling in respiration ; expiration prolonged ; inspiration weak ; and broncophony. Beneath the left there was a well-marked arterial souffle, the blood appearing to be propelled into the stethoscope by each systole ; no dulness or other abnormal sound. This case, highly unfavourable for treatment as it appeared, was just the one to test the value of the theory I have explained. Here was tubercle in the right lung, and the apex of the left lung in that state from which tubercle is formed, complicated with a most formidable disease, epilepsy possibly depending on tubercle in the brain, evidently closely connected with the lung affection—for his mother-in-law and brother were positive that the fits were only brought on by severe coughing. It might be that some of the products of imperfect oxidation, of which I have already made mention, accumulated to such an extent in the brain during the fit of coughing, as to produce by their noxious action the eruptive discharge of Todd ; at all events, it was certain that to cure the epilepsy, it would be necessary to take away its exciting cause—viz., tubercles, and the condition of blood by which these were produced. Having cleared out his bowels with a calomel and jalap purge, I ordered him the following, a bottle of porter daily and

℞ Potassa permang. gr. v.
Aquæ destill ℥i. solve.
Sumat gr. xx., 4tis horis.

I advised him to have a cold bath every morning, and use plenty of soap, and be as much out of doors as possible. After four days, I recommended ℥ss. ol. morrhuæ to be taken *ter die* with the potassa permang. At the end of a week he was improved in appetite and spirits, but the fits continued as before up to the tenth day ; from that time they ceased ;* he gained rapidly in weight ; the cough gradually ceased ; the broncophony, souffle, and dulness became small by degrees and beautifully less, until by the end of September, when considering himself well, he went to Hamilton to a situation, where he now remains.

When a vomica has formed, the indications to treatment are rather more complex. Here, though imperfect oxidation is the determining cause of successive tubercular formations, the mechanism whereby this imperfect oxidation is brought about must claim our prior attention. As the morbid action going on in the vomica is the mainspring which sets the other machinery in motion, an attempt to modify and improve the condition of that cavity would naturally suggest itself to one's mind as the most feasible method of cure ; but such attempts, though repeatedly made by inhalations and injections, have been rendered futile by the spastic condition of the bronchial fibres alluded to, hindering the free application of the medicines employed. But if we first remove bronchial spasm by soothing the excited pneumogastric, and lessen at the same time the abnormal activity of the sympathetic, whereby we remove arterial contraction, enlarge the arterial stream, sweep away capillary congestion, promote the elimination of carbonic acid, and lessen the frequency of the heart's action, we may hope to attack the vomica with success. For this purpose, inhalations of nitrate of silver from 8 grs. to 16 grs. ad. ℥i. may be used by means of the kettle apparatus, or 4 grs. ad. ℥i., by a Richardson's atomizer. At the same time we must inculcate daily ablution of the entire body, open-air exercise, remove acidity by promoting oxidation, guard against unfavourable atmospheric influences, and the occasional dearth of ozone by keeping the blood arterialised, and, as I may be permitted to say, ozonified by permanganas potassa, which, according to Schönbein, contains two or three atoms of oxygen. In that allotropic condition we must give cod-liver oil and an occasional glass of porter. Whiskey is used in this country in large doses, but its effects must be watched carefully. To lessen nervous excitement is obviously of the first importance. For this purpose veratrum viride will be found admirably adapted. Unlike other medicines which "whilst depressing the pneumogastric, excites the sympathetic," it appears to exert a depressant effect over the entire nervous system. The dose, however, can be so adapted that instead of depressant it becomes calmative. Veratrum viride is a powerful, but by no means dangerous medicine; neither botanically nor chemically allied to black hellebore, as its name, green hellebore, would seem to imply, it does not possess the therapeutical properties of that drug. Belonging to the same class and order as veratrum album, it was supposed to possess the same active principle —viz., veratria—a supposition which rendered many diffident of using it. However, it has been shown by Professor Bullock and others, that although its active principle

possesses the physical characters of veratria, they differ chemically: the active principle of veratrum viride forming a colourless solution in cold hydrochloric acid, which heat only slightly deepens, whilst veratria forms a colourless solution with the same menstruum, which boiling changes to an intense red.

Being therefore neither possessed of the cathartic properties of the melampodium, nor of the irritant stimulating qualities of its kindred melanthaceæ, it may be used fearlessly in all cases of nervous excitement, spasmodic affections, and inflammatory complaints. In recommending it in tuberculosis, I do so on physiological principles. The benefits I expect to derive from it consist in lessening the abnormal activity of the sympathetic, thereby reducing the heart's action; relaxing the contracted state of the small arteries, thereby removing congestion; increasing the abdominal secretions, giving an excellent appetite and capital digestion. Removing bronchial spasm, it favours the interchange of gases, facilitates expectoration, and lessens cough accordingly, and as I have said before, the heat of the body. Its effects are similar to alcohol; its mode of action very dissimilar—alcohol supplementing nerve-power, veratrum viride removing undue excitement. Alcohol is most useful where simple nerve-debility exists; veratrum viride where there is undue excitation or irritability.

In phthisis there is a combination of both conditions; hence the administration of both remedies is by no means illogical. Dr. Barker cites a case in which veratrum viride produced no effect on the pulse until he gave brandy. It fell after the first ounce from 130 to 108; after the second it fell to 86. He then withdrew the veratrum and continued the brandy. The pulse rose again in a few hours to 130; withdrawal of the brandy and a continuance of the veratrum had a precisely similar effect. Under the combined influence of the two he kept the pulse below 80 per minute.

When the sympathetic excitation is greatest its effects are most marked. By continuing its employment for some weeks it loses its effects, and eight times the original dose will require to be given.

What chloroform is to tetanus, that is veratrum viride to tuberculosis: it suspends the morbid secondary actions, and we are thereby enabled to attack tuberculosis in its very citadel.

But it may be said its action is exercised directly on the muscular system of the heart and muscular structure in general, and not through the media of the nerves. To ascertain its mode of action I gave a scruple of the fluid extract to a large dog. In a quarter of an hour he vomited, the pulse fell fifty beats, and the respirations were reduced from 29 to 20.

July 12th.—Cut both vagi in a dog. Pulse before the operation 80 to 90, intermitting; after section 140, and steady. In two hours gave ℈i. verat. virid. The pulse fell to 100 in half-an-hour, and became gradually slower until life became extinct, twenty-three hours after the operation. The body cooled so rapidly that it was quite cold long before death.

August 20th.—Got another young dog; cut the right sympathetic above the middle cervical ganglia. Pulse before the operation 98; after fell to 58. Two hours afterwards gave a scruple of veratrum viride. The pulse was reduced only two to four beats, and soon went up again.

In the early part of July a German weaver applied to me, suffering from obstinate hiccough of five years' standing. He had been to all the medical men around and in Buffalo during that time, and being tired of medical men on shore he wished to try those afloat; there was a spasmodic contraction of the diaphragm every two or three minutes; he could hardly jerk out half-a-dozen words consecutively; latterly he could get but very little sleep, and was much worn in appearance. On examination I found the abdomen deeply marked by blisters, and a deep sulcus in the site of the diaphragm. He had angular curvature of the spine, and percussion over the spine between the first and third dorsal vertebræ caused pain. On coming to this country, five and a-half years ago, he was attacked with ague, the hiccough remained as its sequela, and has never left him since. Considering that an irritation of the spine between the tender points was reflected by the phrenic and produced the diaphragmatic spasms, I applied a blister over the tender part, kept it open for a week with ung. hydrarg., and gave him calomel and opium internally. This succeeded admirably for a week, and the patient was in high spirits, when suddenly his old man of the mountain returned, and he was as bad as ever. I now ordered him ung. let for the blister, and ℥ ii. veratri virid fl. ext., *ter die*, ex aqua. A gradual improvement now took place, and in about two weeks the hiccough became periodical, returned only on Thursdays; he went to his work in the States, and I have never heard of him since; a few doses of quinine would probably remove the last vestige of it, but probably he was so delighted at getting so well that he did'nt mind an attack once a week.

This case shows that veratrum viride will remove spasm when caused by excitation of a spinal nerve. Experiment 1 shows that it will depress the general nervous system. 2. That it will depress the sympathetic. 3. That it will depress the pneumogastric, the very slight reduction of the heart's beats, resulting from the depressed effects on the vagi, being counterbalanced by a similar effect on the sympathetic; were its action exercised on the muscular tissue of the heart alone, its effects should be greatest when the heart's power was weakened by section of its motor nerve. Such, however, was not the case.

Richard G——, æt. 24, in last March had an attack of pleuritis. In April he suffered from phthisis; a large vomica rapidly formed in the right lung, and an arterial bruit was heard in the apex of the left. In the early part of July he had sufficiently recovered to be discharged to duty. Being afflicted with constitutional laziness he slept the first night after being discharged to duty in damp blankets, rather than take the trouble to air them. On two or three other occasions he got wet through whilst sleeping under an awning, and the consequence was an attack of pleuritis, and a rekindling of the tubercular disease.

August 5.—The vomica in the right lung extends from its apex to the lower margin of the third rib, and there are unmistakable symptoms of tubercle in the apex of the left. His respirations are 34 per minute; pulse 116; temperature 103°·5; skin dry and burning hot; no appetite; cough frightfully severe; night sweats; sputa copious, excessively offensive; almost fæcal in smell; greyish yellow, frothy, tenacious, striated, and showing trabecula under the microscope, adhering to the vessel. On pouring it into a cup it comes away without solution of continuity; it was covered with two other layers, the top of thinner consistence, containing air-bubbles, the intermediate seen by tilting the vessel on its side, consisting of independent shilling-sized yellowish thick sputæ.

℞ Potassa. permang., gr. v.
Aquæ destillat., ℥i. ℥.
St. gtt. xx., ter die.

℞ Veratri virid, fl., ext. ℥i. and ℥xx.
Morphiæ sulph., gr. iii.
Aquæ, ℥viii. ℥. st. ℥ss., ter die.

℞ Creosoti, ℥ xx.
Alcohol, ℥i.
Aquæ destil., ℥viii. ℥.

One ounce to be inhaled by means of the atomizer morning, noon, and night.

August 9.—Pulse 90; respiration 15; thermometer 99°; expectoration about an ounce, free from smell; skin cooler.

11th.—Pulse 91; respiration 15; thermometer 99°; cough slight; expectoration almost nil; no night sweats; gaining rapidly in weight and spirits; coughed up last night and yesterday several round white pellets, and a few others coated with blood, probably cretified tubercle; skin perfectly cool.

13th.—Respiration 14; pulse 79; skin cool: omit mist. verat. virid.

14th.—Respiration 14; pulse 78; skin cool.

16th.—Respiration 16; pulse 79; thermometer 99°; no sputa; hardly any cough.

19th.—Respiration 20; pulse 80; thermometer 99°; skin *quite cool;* the broncophony and dulness of the left lung have quite disappeared; the vomica in the right has filled up from below, leaving but a small cavity the size of the end of the stethoscope in the apex above the clavicle. I sent him on board; in consequence, however, of the mode of filling up of the cavity, the slight expectoration which remained, not finding a ready passage into the bronchi, produced a good deal of cough when in the recumbent position; for this I found a hot glass of brandy-punch the best remedy, given at bed-time. Fearing the inclemency of the Fall weather, I recommended him for survey, and he was invalided.

September 24th.—Condition thus—Pulse 80; thermometer 99°; respiration 19; hardly any sputa; no cough but at night; still gaining in weight; lung as above described; recommended him to still continue the permanganate and cod-liver oil. I purposely selected the second attack of phthisis this man had, because, *first*, long cases are tedious; *second*, it was of greater severity, and, therefore, better adapted to portray my method of treatment, illustrating by its efficacy the correctness of the theory on which it is based. This patient was not hereditarily predisposed to phthisis, none of his family died from it, he was strong and healthy until the causes already mentioned developed tubercle in his right lung, which progressed with such remarkable rapidity that a vomica of great magnitude was formed in less than two months. Tubercle in its first stage escaped detection; in the second attack the presence of tubercle in the left lung indubitably showed that the disease was true tuberculosis. The effects of potassa permanganes are shown in the arrest, by cretification, of the tubercular action in the left lung, and the subsequent expulsion of cetified tubercle. The inhalations are of great benefit, but should be always employed when nervous excitement has been removed by veratrum viride: it will be necessary to vary the medicines inhaled. Arg. nit. Iod. ferri. mur. ℈i. ad ʒi. are most useful when the expectoration is profuse and fœtid; creosote when there is irritative cough. Alcohol should not be given when the tubercular action is energetic, it will probably induce pleuritis or hæmoptysis. An eminent authority has recently spoken of the fever of phthisis as one quite beyond our control. I would point to the perfect coolness of the skin, and normal pulse of the foregoing case, as an instance of its amenability to a rational treatment.

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

CASE OF HÆMORRHAGE FROM THE DORSAL ARTERY OF THE PENIS OF UNUSUAL SEVERITY.

Under the care of Mr. CROLY.

W. C., aged 27 years, a shoemaker, was admitted into the City of Dublin Hospital in the middle of the night, on account of severe hæmorrhage from the Penis. On inquiry it was ascertained that he had a chancre on the right side of the glans for six weeks, and inflammatory phymosis for two weeks; and that half-an-hour previously to his admission into hospital, while in the act of passing water, the bleeding occurred. He lost a large quantity of blood, and was in a very weak condition.

The Resident Pupils (Mr. Browne and Mr. Finlay) promptly applied pressure on the part, and administered restoratives. Finding that the hæmorrhage could not be thus controlled, a silver catheter was introduced, and a compress placed over the bleeding part, secured by bandage.

This treatment temporarily arrested the bleeding, which, however, soon recurred, and Mr. Croly (the Surgeon on duty) was sent for. He immediately slit up the prepuce, and found a depression on the glans, from which a slough had been partially cast off, and from which there was profuse arterial bleeding. The surrounding diseased surface was freely touched with strong nitric acid, and scraps of lint saturated with the liquor ferri perchloridi fortior were applied to the bleeding point, and retained by a roller (the catheter being still kept in the urethra). The Penis was elevated against the Pubes; a full opiate was administered. The hæmorrhage, which was thus controlled, returned after *four* days with violence, and continued at intervals, resisting treatment. It was consequently found necessary to apply the fine-pointed actual cautery, which, combined with continued digital pressure, proved successful.

Notwithstanding, hæmorrhage occurred again and again as often as *fourteen* times, at varied intervals. On each occasion it was arrested by digital pressure. The patient was consequently much exhausted, and unfortunately got an attack of acute bronchitis, which was treated by dry-cupping and expectorants, his strength being kept up by nutritious diet and suitable stimulants. Opium and tartarised iron were also prescribed on account of the phagedænic ulcer.

The case terminated favourably, notwithstanding the repeated hæmorrhage and the complication of bronchitis.

Mr. Croly made this case a subject of clinical instruction to the class, observing on the unusual severity of the hæmorrhage (resulting from a diseased state of the artery), which resisted the ordinary treatment, and which recurred with so much violence on several occasions, requiring the actual cautery and careful digital pressure, which was effectually applied by the resident pupils. He also explained the necessity of slitting the prepuce, on account of the inflammatory phymosis, to reach the bleeding-point, and detailed the several modes of arresting such form of hæmorrhage. The constitutional treatment by opium and tartarized iron was also dwelt upon.

MATER MISERICORDIÆ HOSPITAL.

PARTIAL RUPTURE OF RIGHT RECTUS ABDOMINIS MUSCLE.

Under the care of Dr. HAYDEN.

JOHN S., aged 50, a labourer, was admitted into hospital February 10, 1868. Two years previously he was caught between two carts, and was hurt in the lower part of the right side, but not disabled from work. Six weeks ago he was attacked with severe pain in right side, which was aggravated by coughing, and one week prior to date of admittance he strained himself whilst tying a load of straw, and felt sharp pain in the right side of the abdomen, superiorly. The man seemed in good health, was hale-looking and free from febrile symptoms; tongue moist and clean; no jaundice. He complained of acute pain in the abdomen on making a full inspiration, or any movement of the body involving contraction of the anterior abdominal muscles.

About two inches below the margin of the right costal cartilages, and over the right rectus muscle there was a slight fullness, tender on pressure, nodular to the touch, resonant on percussion, and extending nearly quite across the muscle; this was the seat of pain above referred to.

The man was kept at rest for a few days, and a small blister was applied over the swollen and tender part. He was dismissed quite well.

The injury which this poor man had sustained in the right side two years before admission, and the acute pain which he subsequently felt there, taken in connection with the locality of his present suffering, might, and in the mind of a medical gentlemen of experience who saw him before he came under Dr. Hayden's notice, actually *did*, lead to the suspicion of injury or disease of the liver, but the absence of general symptoms, and the precise situation,

and percussion resonance of the swelling, excluded this hypothesis, whilst the history of muscular strain a week previously, the situation of swelling and tenderness, and the absence of pain, save during contraction of the rectus muscle, served to establish a positive diagnosis.

Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By C. R. C. TICHBORNE, F.C.S.L., Etc.,

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ISOMERIC FORMS OF VALERIANIC ACID.

It is well-known that there are two isomeric amylic alcohols (fusel oils), one of them does not rotate a ray of polarized light, whilst the other does. Messrs. Frankland and Duppa state that ordinary valerianic acid rotates a ray of polarized light to the right; whilst Wurtz asserts that ordinary valerianic acid is without action upon a polarised ray. Mr. Alexander Pedler has been experimenting with a view to determine if there are two acids corresponding to the two amylic alcohols. He finds that there are two; and that they can be prepared with ease from their respective alcohols by the ordinary oxidizing process.

The amylic alcohols were prepared by making sulphamylate of barium from the ordinary fusel oil, and separating the mixed sulphamylates by fractional crystallization; the barium compound obtained from the active amylic alcohol being about two and a-half times as soluble as that obtained from the inactive amylic alcohol. The two amylic alcohols were then obtained by decomposing their respective sulphamylates. The amylic alcohol obtained from the less soluble sulphamylate had a boiling point at 129° C., a penetrating and oppressive odour, which produced coughing, and a burning taste. In the polariscope it was found to be perfectly incapable of rotating the ray of polarized light.

When this alcohol was oxidized in the ordinary manner, no effervescence was observed; and the valerianic acid obtained, boiled at 175° C., and had the characteristic odour and taste of ordinary valerianic acid, it had not the slightest action upon the polarized ray.

The active alcohol, when treated with oxidizing agents, evolved abundance of carbonic anhydride, and produced a large amount of acetic acid. The acid boiled at 170° C., and had the same disagreeable taste and smell as the inactive acid; when tested with a ray of polarized light, it gave a right hand rotation of 43 degrees in a tube 50 centimetres long.

The above experiments indicate either that the non-rotating valerianic acid of Wurtz had been made, as suggested by Frankland and Duppa, from a non-rotating sample of amylic alcohol, or that the acid made from the mixed alcohols had been allowed to remain in contact with the oxidizing mixture sufficiently long to destroy the whole of the less stable rotating acid.

ESTIMATION OF SULPHUR IN COAL GAS.

Mr. Wm. Valentine, in a communication to the *Chemical News*, takes exception to the modes in use for estimating this important impurity. Although he says that Dr. Letheby's process is the best published, he also states that it does not comply with the requirements of a *quantitative test for sulphur*. In fact, that it never tells, even approximately, how much sulphur is in the gas. Dr. Letheby's arrangement entails a loss varying from three-fourths to four-fifths of the bisulphide of carbon in the gas. Mr. Valentine's arrangement consists of meters for measuring the gas and air (the latter being mixed in slight excess), and passing them through a tube in a combustion furnace; the tube contains spongy platinum, by this means the whole of the sulphur compounds are oxidized into sulphuric acid, which is estimated in the ordinary manner. The sulphuric acid being collected in a flask containing soda.

FREEZING OF WATER AND BISMUTH.

It has been received as a conclusive fact, that water presented an exception to the general rule of contraction with the abstraction of heat. Professor Tyndall, in his work entitled "Heat considered as a Mode of Motion," when speaking of the apomalous expansion of water prior to solidification and the importance of this property in the economy of nature, controverts the generally received opinion, that no other bodies possess this property, and cites bismuth as another exception. If melted bismuth was poured into an iron bottle, and the latter was closed with an iron screw—the metal on cooling expands sufficiently to burst the bottle. "There are no fish here to be saved," says Professor Tyndall, still the molten bismuth acts exactly as the water acts. Mr. Alfred Tribe controverts the conclusions of Professor Tyndall, and says the above experiment shows conclusively that molten or fluid bismuth expands either on cooling or freezing, but it affords little or no proof of that which has been inferred from it.

From experiments made with bismuth, paraffin, potassium, and sodium salts, it would appear that their solidification always commenced from the bottom. In every experiment made with water it commenced at the top. It therefore appears as a rule that substances solidify upwards, water being the exception. It is certain that bismuth follows the rule whether water be the only exception or not.

As soon as a liquid begins to cool, its temperature ceases to be uniform. The necessary consequence of this must be a difference in the specific gravity of the different particles, which will arrange themselves accordingly. After a short time the denser particles will be found at the bottom, and as solidification begins there, the conclusion may be drawn that the point of greatest *density coincides with that of solidification*, and it stands to reason, that the particles which solidify first are the coldest. It may be concluded from this, that molten bismuth on cooling down does not expand before freezing, as is the case with water, but that it continues to contract down to the solidifying point. The rapid expansion, which is well-known to all chemists, is due to the act of crystallizing. The reason why the metal does not rise to the surface as soon as it becomes solid, although specifically lighter, is simply because it adheres to the bottom and sides of the vessel. Hence the analogy of bismuth and water is not perfect, and fails just in that point which causes our rivers and lakes to freeze from the surface, and thus to protect animal life.

FORMATION OF OXALIC ACID FROM CARBONIC ACID.

This very important reaction has been effected by Dr. Dreschsel. When a mixture of pure sodium and recently ignited sand is heated in a flask imbedded in a small sand-bath to the temperature of boiling mercury, while a rapid stream of dry carbonic acid gas is continually passed through the vessel, the sodium becomes converted into a dark-coloured pulverulent mass, which is found to contain oxalate of sodium.

Sixty grains of sodium yielded six grains of oxalate of lime.

Potassium-amalgam absorbs carbonic acid gas at the boiling point of mercury even more energetically, and yields a somewhat considerable quantity of oxalic acid.

DETECTION OF KREATININE IN URINE.

M. Roussin proposes the use of bichloride of mercury for the detection of kreatinine in urine. Kreatinine is precipitated from its solution by the mercurial salt.

ELECTRICITY AND THE CHOLERA.

An Italian savant (Father Denza) has been studying the condition of the atmosphere during the prevalence of the cholera in Turin. During August and September, when the cholera was at its height, the amount of ozone present was variable, but about the average. The electricity, however, during these months almost entirely disappeared. This is a curious observation and one difficult to account for.

ON VANADIUM AND ITS COMPOUNDS.

The metal vanadium was discovered by Sefström in Swedish bar-iron. Even when using many pounds of the iron, only minute quantities of the substance could be procured. In the present day the vanadium compounds must be reckoned amongst the greatest chemical rarities, and they are quoted in the price-lists of chemical dealers at £35 per ounce. Sefström handed over his preparations to Berzelius, to whom we owe almost all our acquaintance with the chemistry of vanadium, except in one instance, when doubt was thrown upon Berzelius' researches.

Prof. Roscoe came into possession of a plentiful source of this rare substance, and therefore devoted his time to investigate the experiments of M. Berzelius. He described them at an evening meeting of the Royal Institution.

Berzelius came to the conclusion that the most characteristic feature of this substance is the existence of an acid-forming oxide, termed vanadic acid, produced whenever the oxides are heated

in the air. He also discovered two other oxides of vanadium; also a chloride. The atomic weight of the metal Berzelius said was 68·5. He came to this conclusion from the following experimentally-ascertained facts:—1. That on passing hydrogen over heated vanadic acid, a constant loss of weight occurred, and the sub-oxide was formed. 2. That when dry chlorine was passed over the suboxide thus prepared, the volatile chloride was formed, and a residue of vanadic acid remained, which was exactly equal in weight to one-third of the acid originally taken for reduction.

Hence, assuming that the lowest oxide contains one atom of oxygen (an assumption borne out by the analysis of the chloride), the acid must contain three atoms of oxygen; and the following formula represents the composition of these compounds, according to Berzelius:—

$VO \quad VO_2 \quad VO_3 \quad VCl_3 \quad (V = 68{\cdot}5)$.

Oxides——————— Chloride—

From observations of Rammelberg in 1856, the mineral vanadinite was added to a list of isomorphous minerals, all of which minerals had an analogous composition.

Apatite $3\,(Ca_3\,P_2\,O_8) + Ca\,Fl_2$

Pyromorphite $3\,(Pb_3\,P_2\,O_8) + Pb\,Cl_2$

Mimetesite $3\,(Pb_3\,As_2\,O_8) + Pb\,Cl_2$

As before said, vanadinite was isomorphous with the above. So far, indeed, has the identity of crystalline form been traced that crystals have been found which at one end consisted of vanadinite, and at the other pyromorphite. A formula to agree, however, with the above minerals would require an oxide of vanadium agreeing with the corresponding oxides of phosphorus and arsenic (V_2O_5). This would not, however, agree with Berzelius' formula.

Prof. Roscoe has, however, proved that the substance supposed by Berzelius to be vanadium ($V = 68{\cdot}5$) is not the metal, but an oxide, and that the true atomic weight is $68{\cdot}5 - 16 = 52{\cdot}5$ (according to the author's exact determination by experiment, 51·3).

Thus, the true composition of the vanadium compounds are as follows:—

$V = 51{\cdot}3.V_2O_2 \;—\; V_2O_3 \;—\; V_2O_4 \;—\; V_2O_5 \;—\; VO\,Cl_3$

Dioxide. Trioxide. Tetroxide. Pentoxide. Oxytrichloride.

Each of these four oxides have been obtained, the dioxide being a grey metallic substance.

Solid oxychlorides are obtainable, one of which resembles mosaic gold, possesses a bright metallic bronze-like lustre, and has been taken for the metal by Schafarik. The metal itself has not been obtained.[1]

Vanadium is the fourth substance supposed by their respective discoverers to be metals, which has on investigation within the last few years been shown to be a compound body.

CULTIVATION OF JALAP IN ENGLAND.

Mr. Hanbury stated at the Pharmaceutical Society that a plant of jalap which had been left in the ground all the winter and thrived, had produced six large tubers and twenty-four small ones. He (Mr. Hanbury) was of opinion that it grew better in the open air than under glass. Unfortunately, however, the flowering was too late for the seed to ripen. There is little doubt that this important medicinal plant might be cultivated with success in Europe.

EXTRAORDINARY MINERAL WATER FROM JAMAICA.

Prof. Attfield has analysed this water, and finds it to contain 2493¼ grains of mineral matter to the gallon, viz:—

Chloride of Calcium	1510
Chloride of Sodium	981
Chloride of Ammonium	2·43

So that a gallon contains 3½ ounces of chloride of calcium. The proportion of chloride of calcium is unprecedented. The negroes believed in it as a cure for every disorder, but it was chiefly used for scrofulous affections, glandular swellings, &c. The author quoted from Pereira's statement of the therapeutic action of chloride of calcium, which shows that it is most useful in those diseases for which the negroes have recourse to the medicinal water.

PRESERVATION OF ANIMAL FOOD.

Of all the numerous patents that seem at all successful,[2] Messrs. Medlock and Bailey's promises the most fairly. It is well spoken of by those that have tried it, and it seems daily growing into favour. Mr. W. H. Scott read a long paper at the Society of Arts on the Preservation of Animal Food, when he pointed out the great importance of the question.

Speaking of the consumption food, he says that there is available for the use of the British Isles less than two ounces of meat per diem (including bone and fat) per head of the population. As each person should consume on an average not less than ten ounces per diem, it is evident that the meat supply is perfectly inadequate, and the corollary follows that if this amount of animal food be necessary to the maintenance of the constitution, we are actually in a state of social starvation. The importance of the preservation of food becomes therefore of more vital importance from day to day.

The antiseptic class of preservatives of animal food seem the most successful, and the author of the above-named paper includes under this head those methods which depend upon the addition of some substance, which, by a simple property known as catalysis, prevents or arrests oxidation or putrefaction by its mere presence, undergoing no change in itself, or but very little. To a greater or less extent salt, sugar, creosote, carbolic acid, &c., possess this property, and are constantly employed for this purpose, either separately or as mixtures. The numerous applications of "cured" or "salted" meats are well known. They are wonderfully improved, if, after salting, they are submitted to the influence of wood or peat smoke, during which process a minute quantity of acetic acid and creosote is absorbed.

Sulphurous acid has frequently been employed alone for the preservation of meat, but has failed in all instances from its volatile nature, causing it to be dissipated too soon to be of any real protection. Messrs. Medlock and Bailey's patent consists in the use of bisulphite of lime. The neutral sulphite of lime is only slightly soluble in water, and its antiseptic properties are not so well marked as those of the bisulphite, which contains double the amount of sulphurous acid, is perfectly soluble, and when oxydized is merely converted into sulphate of lime. The author gave analyses of beef, mutton, veal, and pork, both before and after treating with the bisulphite process, to show that the constituents of the flesh were very little changed. He said that in this preparation he believed we had a means of converting to our use the enormous meat stores of Australia and South America, and that he looked forward with confidence to seeing beef and mutton imported for sale at 2½ to 3 pence per pound, and of a quality equal to any we can procure.

ON THE DECOMPOSITION OF SYRUPUS FERRI IODIDI.

Dr. E. Squibb (*American Journal of Pharmacy*, March) recommends the addition of a solution of hyposulphite of soda to discoloured syrup of iodide of iron. He used a solution of 15 to 20 grains of crystallized hyposulphite to the ounce of water—from 15 to 20 minims of this solution are sufficient for a pint of the syrup, when the latter is not very discoloured. He says that syrup so restored is afterwards much less susceptible to change, and the writer suggests that the addition of a minute proportion of hyposulphite of soda to fresh syrup, will probably secure it against change.

CHLORATES OF CINCHONA ALKALOIDS.

M. C. Lewis Diehl, in the *American Journal of Pharmacy*, writes upon this subject. He commences by giving "Tichborne's process for preparing chlorate of quinia, and Bottger's process for preparing the chlorates of barium. The latter process of M. Bottger is not the only one by which this salt is manufactured. It has been commercially manufactured and used within the last two years in England and France, and we have no doubt that it will soon find its way to America. Its principal use is for pyrotechnic purposes, but its great advantages for the preparations of the other chlorates and the oxychloric acids are so evident, that it will no doubt soon become an important commercial salt.

Mr. C. Diehl describes a bichlorate of quinia, obtained by decomposing bisulphate of quiniæ with chlorate of baryta. When placed upon heated platinum foil it immediately explodes with great violence. It has not, however, been obtained in crystals.

Chlorate of quinidia may be formed in a similar manner to the quinine salt. It crystallized quite distinctly from that salt, however, viz.—in forming solid tubular crystals which were entirely derived from the rhombic system.

Ferrocyanate of quinia the author makes by boiling two

1 A specimen having a bright metallic lustre was shown at the Paris Exhibition; but this must of course have been Berzelius' protoxide.—Ed. S.

2 There have been some hundreds of patents taken out for the preservation of food.

parts sulphate of quinia with three parts ferrocyanide of potassium in a little water, to pour off the liquor from a greenish-yellow substance, which, after cooling, is dissolvent in alcohol. If the alcoholic solution is evaporated to dryness on a water bath, with the aid of heat, a greenish-yellow powder remains, but if the solution is allowed to evaporate spontaneously, the result is a light yellow substance. Pelonze found the green substance to be a mixture of quinia and Prussian blue, but, says the writer, it would be difficult to see how a mixture of quinine and Prussian blue would form a light-yellow compound. It is therefore probable that the ferrocyanate of potassium is a definite compound, which is decomposed by heat.

Literature.

THE STOMACH AND DUODENUM.[1]

We hold it to be one of the best signs of our day as regards the future of medicine, that there are so many able and earnest labourers at work in the field of observation and research, and among them all we know none more meritorious than Dr. Fenwick. The amount of patient questioning of nature, of which this volume contains the results, can scarcely be appreciated except by those who have had some experience of similar labours. The philosophic medical inquirer who goes to the fountain-head for information, works often at great disadvantage compared to others. A chemist or physicist can lay his plans for experimentation, collect his materials, and when all is ready, proceed at his convenience, and with undivided attention, to the investigation he has in hand. Not so the pathologist; the opportunity for observation comes, he knows not when, very likely at a time when his hands are full of urgent business, and his energies are called away from the exercise of accurate research and reflection, to efforts to relieve human suffering as best he may. The informing idea of Dr. Fenwick's inquiries has been to trace the relations of morbid changes in the stomach and intestines, not only to the functions of the organs themselves, but especially to the disorders and textural lesions of other parts. The condition of the stomach in fevers, in diseases of the heart, in diabetes, in hepatic disorders, in phthisis, renal disease, and in delirium tremens, forms the subject of several chapters devoted to these subjects. Besides these there are chapters on acute, subacute, and chronic gastritis, on weak digestion, on dilatation of the stomach, and on ulceration. An appendix contains the results of some statistical inquiries into various causal conditions, productive, or supposed to be productive, of dyspepsia. The influence of smoking, of alcoholic drinks, of deficiency and excess of animal food, of imperfect mastication, of anxiety of mind, of age, and of hereditary transmission is thus inquired into. As to the last, it appears that a tendency to infirmity of the digestive organs is very often transmitted. Out of those liable to dyspepsia, 45 per cent. were the offspring of parents who had suffered from the same disorders, but of the healthy only 12 per cent. gave the same history. Smokers may find comfort in Dr. Fenwick's figures, for although he set out with the preconceived opinion that the habit was noxious to digestion, he found himself compelled, by the evidence of facts, to modify his view. The teetotallers will, perhaps, be surprised to learn that among dyspeptics 45 per cent. of those examined were total abstainers, while among the non-dyspeptic there were only 19 per cent. of their creed. Dr. Fenwick, however, while entertaining no doubt as to the beneficial effect of malt liquors, especially in females, writes wisely and well, that "it is far wiser to suffer any amount of dyspepsia than to subject oneself to the innumerable evils resulting from drunkenness." This applies to persons who are unable to be temperate. In all the chapters treating of the subjects above-mentioned, the reader will find valuable and often original information, and it is plainly impossible for us in these narrow limits to do more than notice some of the points which have most arrested our attention. Dr. Fenwick recommends auscultatory percussion as the best means for determining the space occupied by the stomach. The cup-shaped end of a Camman's stethoscope is placed over the viscus, while the observer listens to the sound produced while the surface is smartly tapped with the fingers. The shock of the tap is felt directly in the ears, and continues to be as long as the stethoscope is placed over the stomach. By this proceeding the limits of the organ can be ascertained, and may be marked on the surface with ink. We are glad to see that Dr. Fenwick restores gout to its former position as a cause of gastritis, which some have recently refused to it; there can be no reason, to our thinking, why lithates circulating in the blood should not irritate the gastric quite as much as the bronchial mucous membrane, which is notoriously prone to be thus affected. He gives an interesting communication from that excellent observer, Dr. Marston, as to the occurrence of acute gastro-duodenitis in consequence of pyæmic, malarial, or uræmic poisoning. We should like to have had Dr. Fenwick's opinion as to the use of opium in cases of gastritis from poisoning, attended as they mostly are with great prostration. Might not opium lessen the depression if given in properly adjusted doses?

We have perused the section on the state of the stomach and intestines in phthisis with interest, hoping that the searching scrutiny to which the organs had been subjected, might have shed some light on the origin of this yet most obscure malady. The riddle, however, is not yet solved. Dr. Fenwick comes to the conclusion "that neither in man nor in the lower animals are there any anatomical changes in the stomach or in the upper part of the intestinal canal *peculiar* to phthisis." Yet his own inquiries strongly corroborate those of previous observers, which have tended to show that it is not improbable that tubercle may result from an imperfect action of the organs of digestion. In 100 out of 200 cases there had been a distaste for fat previous to the commencement of the phthisis, and other forms of dyspepsia had prevailed in others. The author dwells somewhat particularly on the predominance of gastric symptoms in certain cases of phthisis, and his statements on the subject are well worthy of perusal. The following passage sums up his views relative to the genesis of tubercle:—"It appears to me that the chief cause leading to the actual production of tubercle is an activity of growth in the tissues disproportioned to the amount of healthy nutriment presented to them. In the normal condition the power of the digestive organs is regulated by the requirements of the system; hence the keen appetite and the rapid absorption of the young. But if the growth of the body progresses more quickly than the digestion can supply a sufficient quantity of properly constituted material, then matter of an inferior organization will be taken up and employed in nutrition, and disease must be the result"—p. 207. Anything which hinders the due formation of reparative material may act in this way as a cause of phthisis.

The chapter on the connection between affections of the brain and the digestive organs, embracing what is sometimes termed "nervous dyspepsia" betokens evidently the experienced and skilled physician. Dilatation of the stomach is the subject of another very interesting chapter. The diagnosis of this condition, at an early period, is very desirable, because at this time degeneration of the muscular coat is not so far advanced as to make all attempts to repair the mischief fruitless. Dr. Fenwick recommends in doubtful cases to induce vomiting early in the morning, and to examine the ejecta with a view to ascertain whether a considerable quantity of the food taken on the previous day has been retained in the stomach or no. If this is the case, and the vomited matters contain torulæ and sarcinæ in numbers, there can be little doubt as to the existence of some impediment to the transmission of food from the stomach. He does not, however, mention a proceeding which was proposed some years ago by an enthusiastic Frenchman, who affirmed the practicability of passing a sound down the œsophagus and *through the pyloric orifice* of the stomach! The dilatation is held by our author to be the "fons et origo mali," and he does not think that an effectual cure is accomplished by remedies which only have for their object to arrest fermentation, such as the sulphites. Ulcers of the stomach are grouped by Dr. Fenwick under several heads, this being, he considers, the most likely means of arriving at correct conclusions. He distinguishes—1. Sloughing ulcers caused by debility; 2. Ulcers accompanying passive congestion from disease of the heart or liver: 3. Ulcers induced by inflammation; 4. Chronic ulcers, of which he says, that in nearly every case which he has examined with the microscope, the blood vessels have been diseased. We are glad to find this able physician feels the same difficulty which we have so often felt ourselves—viz., that of pronouncing a positive opinion as to the existence or not of chronic ulcer of the stomach. For aid in this matter, he offers some suggestions. If, in a doubtful case, the shape of the stomach is evi-

1 The Morbid States of the Stomach and Duodenum, and their relation to the Diseases of other Organs. By S. Fenwick, M.D. London: John Churchill and Sons.

dently altered, or its size enlarged, or if portions of detached pancreatic tissue are found in the stools, some material evidence is thereby obtained.

Our space is exhausted, but not the list of topics to which we might invite the attention of our readers. We are sure they will agree with us in regarding this volume as a standing proof of the industry and intelligence of the author, and of the high rank he deserves to hold among the scientific physicians of present and past time.

This work,[1] written by an eminent German physician, has a three-fold object. First, to remove from the minds of patients the exaggerations and the causeless alarms many of them entertain, in regard to the nature and consequences of their maladies. Secondly, to afford such correct and clear information in respect to the symptoms of the various forms of debilities treated of, as will enable them to distinguish between the imaginary and the real. And, thirdly, to withdraw their treatment from the domain of empirics and empiricism, and place it on a basis of common sense and scientific medicine. The author appears to have fully investigated these causes, and we have therefore much pleasure in recommending this work to the attention of that portion of the profession interested in the subjects on which it treats.

Dr. Wynn Williams explains in a pamphlet of 23 pages[2] his plan of treating cancer of the uterus by the application of bromine.

Dr. Collins[3] weaves into a little *brochure*, all the prejudices and all the fears that have been uttered in respect to vaccination. He can scarcely expect that his opinion will over-ride that of the whole profession, and we think he can only look for approval to such one-sided persons as Sir J. Jervoise, whose performances in the House of Commons resemble those of Dr. Collins in print. There is a certain liveliness in Dr. Collins's style, and a touch of grim humour in his telling how he sent in his essay to compete for the prize offered by the Ladies' Sanitary Association, but confesses he had little hope of attaining it, when he heard that "two rabid vaccinators" (sic.) had been appointed adjudicators.

PROFESSIONAL EDUCATION.

AT the distribution of prizes at University College last week, Mr. BRUCE as chairman, gave a very able address, in which he adopted, to a large extent, the views on medical education put forth by Mr. SIMON, and which we have already noticed. Mr. BRUCE said not long ago he read a statement made by that gentleman, of whose honesty and purity of motives he could confidently speak, to the effect that any person might enter the Medical Profession by the mere fact of his having obtained a knowledge of one branch of the profession only. He might pass a surgical examination and be admitted to practice in medicine. There were 577 practitioners holding only the diploma of Apothecaries' Hall, which did not imply of necessity any knowledge of surgery, or any adequate knowledge of anatomy; and out of a total of 20,000 practitioners upwards of 5000 were not qualified by law to practise more than one department of their profession. Another statement met with by the Chairman was that in the year 1866 or 1867, in the registration list under the Medical Act, there were 345 diplomas of membership of the Royal College of Surgeons, 191 licences of the Apothecaries' Company, but only 12 degrees derived from the University of London. He said we were the only people in Europe—certainly the only great nation—that admitted to the medical profession gentlemen who had only passed an examination in one branch of that profession. And what was the result? It was this—that in the year 1866 the Army Board had before it 14 candidates who were members of the Royal College of Surgeons, and that four of them failed to pass the re-examination, or, as it was called at the Universities, were "plucked." What happened to another batch of gentlemen who presented themselves for examination at the Navy Board? There were six candidates who were members of the Royal College, and their fate (arranging them in the order of merit) was this:—No. 1 passed "good," but he had failed twice before; No. 2 passed "indifferent, and deficient in anatomy;" No. 3 rejected, "ignorant of anatomy and surgery;" No. 4 rejected, "ignorant of anatomy and surgery;" No. 5 rejected, "ignorant of anatomy, surgery, and practice of medicine;" No. 6 rejected, "ignorant in all branches."

Mr. BRUCE further remarked that in Germany a similar condition of things prevailed until admission to the universities was made to depend on the passing of a severe examination, and he seemed to think that the only way of improving the state of medical education was to enforce a stringent preliminary examination.

It is undeniable that the student who brings to the work of learning the art of medicine a sound general education must make a more rapid advance (and his work must be by that much more agreeable) than he who has to toil his way painfully through subjects with which he should be familiar.

There are plenty of preliminary examinations recognized by the Council—any one of which would, we believe, be found enough for ordinary purposes. The worst of it is the want of uniformity in the requirements of the several bodies. It seems a great pity that this preliminary education should not be let alone altogether by medical corporations, for passing at one of these is no use for any other purpose, whereas an examination by the Universities, the natural bodies to which to commit this duty, would bring the students into relation with these institutions, and frequently lead to there graduating where they had matriculated.

This is a point of very great interest, and one to which we intend shortly to return, for to the disgrace of the Medical Council, be it said, the student is bewildered by the hundred-and-one paths he is at liberty to choose from to enter the profession, and the thousand-and-one regulations which are to guide him along any of those devious paths he may select.

Mr. BRUCE then coupled sanitary reform with the improvement of medical education, and professed himself

1 On True and False Spermatorrhœa. Translated from the German of Professor Pickford, of the University of Heidelberg. Seventh Edition. London: H. Bailliere, Regent-street.

3 Have you been Vaccinated, and what Protection is it against Small-pox? By J. Collins, M.D. London: H. K. Lewis. 1868.

ready to work for both. He bore his testimony to the labours of the profession in every kind of good work, and called upon the young men he addressed, and who were about to commence an honourable career, while their first aim would naturally be to attain to a high place in their profession, not to forget that it was their duty as citizens to take part in those improvements in the sanitary condition of the people which up to this time the medical profession had cultivated more than any other portion of the community.

ST. THOMAS'S HOSPITAL.

The foundation stone of the new hospital has been "well and duly" laid by the Queen, amidst the enthusiastic plaudits of a brilliant assemblage, who delighted to welcome back the Sovereign to public life. We have not space to describe the brilliant scene, nor to reprint the formal addresses, but we take the opportunity of noticing some of the most interesting points suggested by the event. The origin of this Royal charity dates back to 1213, when the Prior of Bermondsye founded an Alms-house. This, in 1539, was purchased by the City of London, and became one of the five royal foundations. It grew and prospered, and many are now in practice who received their education within its walls. It is but recently that the Charing-cross Railway purchased the buildings for £296,000, and so rendered it necessary to obtain a new site. We have no intention of reviving the controversy as to the fitness of the site selected at Stangate—on a piece of land reclaimed from the Thames in making the Southern Embankment. Nearly facing the Houses of Parliament, the new hospital will be an ornament to London, and a blessing to the densely-populated district around.

The foundations of the new buildings seem to be solid enough—a depth of concrete varying from 5 feet to 26 feet in thickness. It is believed that there need be no fear of the patients suffering from offensive effluvia from the river, since the quantity of deposit exposed at low tide must be very small, now that the main drainage system may be said to be carried out, besides which the river is now a comparatively narrow channel, bordered on each side by granite walls of great thickness. It has taken a year to construct these foundations, and the cost is estimated to be at least £40,000.

The hospital will be built on the pavilion principle, and consist of eight blocks. The first block, the nearest to Westminster Bridge, will be devoted to administrative purposes. The second and third blocks will be for the Nightingale Training Institution. The several pavilions are 125 feet from each other. The medical school will be separated by a still wider interval, and museum, library, lecture rooms, and anatomical theatre are all duly provided for.

The wards will occupy the six central pavilions, which will all be built on the same plan. Each pavilion will be a distinct hospital with its kitchens, laundry, and other appurtenances. Each ward will run the whole width of the building, and be 120 feet long by 28 wide, giving a cubic space of 1800 feet for each patient. This, though it seems large, will not be too much when it is remembered that the hospital admits cases of the greatest danger, and is likely to have all its beds constantly occupied. The windows will be between the beds, and at those facing the river there will be balconies, where some of the patients may in fine weather enjoy the fresh air and the fine scene. Contagious diseases will be disposed of differently. The block devoted to them is to have a central staircase, and there will here be two wards on each floor.

Thus, St. Thomas's Hospital will enter on a new chapter of its long and honourable history with all the appliances that science can suggest for carrying on its great work. It can scarcely fail to prove a lasting benefit to the Metropolis, and as a charity and a medical school, its future seems secure. It was well for the Queen to venture from her long retirement to inaugurate so noble a work, one which, as Her Majesty's reply to the address remarked, "naturally attracted the attention" of her "beloved husband whose heart and mind were ever interested in institutions of so beneficial a character," but one which happily is not alone in its great object of alleviating human pain.

THE LORD MAYOR OF DUBLIN.

On the 14th instant, a deputation from the Corporation of Dublin, headed by the Lord Mayor, was introduced to the Royal presence at Windsor Castle, and presented a loyal address, congratulating her Majesty on the escape of H.R.H. the Duke of Edinburgh from the hand of a Fenian assassin at the antipodes.

The *Court Circular* proceeds to say that "Her Majesty received the address, and returned a gracious answer. The Lord Mayor of Dublin was then presented to her Majesty by the Lord Chamberlain, and received the honour of knighthood."

As the Lord Mayor of Dublin is a member of our own profession, we take this opportunity of congratulating him on his recently-acquired honour; and in doing so we believe we only express the general feeling of the community when we say that the presentation of the honour of knighthood to Dr. Carroll will be received with feelings of satisfaction as the just reward of irreproachable conduct and princely hospitality in his official position. During the late visit of H.R.H. the Prince of Wales to Dublin, Dr. Carroll well sustained the traditional high position of the Lord Mayor of Dublin; and his honorary distinction obtained for this reason may well be compared with similar honours granted, as they often are, to reward the aristocratic toady, and the time-serving political place-hunter.

THE DUBLIN MAGISTRACY.

His Excellency, the Lord Lieutenant of Ireland, has recently appointed Dr. George B. Owens, of Kildare-street, Dublin, to the Commission of the Peace for the County of the City of Dublin. We congratulate Dr. Owens on his appointment to the magistracy; and we do this *ex animo*, because few men in our profession have done more to serve the substantial interests of its underpaid members than he has. As a well-known and zealous Poor-law Guardian for several years, Dr. Owens has always been found on the side of true liberality to the sick poor; and it is in a great measure due to his unceasing efforts, that the professional position of our brethren, the Union and Dispensary Medical Officers of Dublin, has been materially improved of late years.

Notes on Current Topics.

The Public Health.

We find in the return by the Registrar-General, for the week ending Saturday May 9, both fewer births and fewer deaths in London, and 13 other large towns of the United Kingdom. The numbers were 4805 births, and 2903 deaths—24 per 1000 being the annual rate of mortality, distributed in the following proportions:—22 London,

Edinburgh, and Leeds ; 30 Glasgow ; 28 Manchester ; 26 Dublin and Bristol ; 25 Liverpool and Bradford ; 24 Salford ; 23 Sheffield ; 20 Birmingham and Newcastle-on-Tyne ; and 19 Hull. The deaths registered in London were less by 37 than the estimated number.

The deaths from zymotic diseases were 286 ; 17 deaths from small-pox, 55 from measles, 28 from scarlatina, 5 from diphtheria, 69 from whooping-cough, 38 from fever, and 19 from diarrhœa were registered.

Two hundred and six deaths occurred from phthisis, 106 from bronchitis, 63 from pneumonia, 58 from diseases of the heart, and 175 from diseases of the brain and nervous system.

Five children and two adults died from burns or scalds ; 6 persons from drowning ; 7 infants from suffocation ; 9 persons committed suicide, and 8 were killed in the streets by horses or carriages.

Health of Manchester.

Everyone who has noticed the periodical health returns of the United Kingdom, must have been struck with the high rate of mortality constantly reported of this important city. It is satisfactory, therefore, to receive the first sanitary report of Mr. Leigh, who has recently been appointed medical officer of health. It appears that diseases of the respiratory organs which are fatal enough everywhere, are much more so in Manchester than in most other towns. This may be accounted for in great measure from atmospheric conditions. "Ozone is never found in the air, and the normal condition of the working-man of middle age in this city is bronchitic." Infectious diseases, also, which are often brought into the city by persons who have contracted them elsewhere, destroy large numbers, from the habit of the poor, who, when a disease prevails, thoughtlessly visit their friends and neighbours who are ill, and, consequently, carry home and spread the infection. Very thoughtlessly too, in a vast many cases, they take their children with them as well, and hence it may not be surprising that one-half of the deaths occur among children under five years of age. As many as 16,549 persons died of infectious diseases in Manchester and Charlton, in the ten years 1851-61, and in the seven years 1861-7, in the same districts, including Ardwick, there were 10,443 fatal cases from such diseases, exclusive of those occurring in private practice. What may be the sanitary condition of the districts, there are no particulars to show; but no doubt an investigation will be commenced without further delay than is necessary. The first step Mr. Leigh advises is to take immediate and decisive measures to reduce the death-rate from infectious diseases, by preventing persons afflicted with them from conveying the disease through injudicious intercourse, and by the isolation of the infected sick. This, of course, will involve the necessity of largely increased hospital accommodation, but to what extent cannot at present be ascertained. He invites his friends at the union hospitals to furnish him with facts which may help him to form an accurate judgment on the point. His observations on the subject of infant mortality he will present in a subsequent report. Meanwhile we may hope that the efforts he is making will be followed by marked and beneficial results.

University of London.

Lord Granville, as Chancellor of this University, delivered a very able address at the convocation last week. We regret not having space for a full report of the speech, but many of our readers will, we doubt not, have perused it in the daily papers. His Lordship spoke strongly in favour of the education of females, although he was against mixing them up with young men in their proposed examinations—a reservation which, we think, will commend itself to the major part of the public.

The Chancellor touched also upon the medical importance of the university, and on its recent acquisition of the right to send a representative to Parliament.

In reference to this last subject, we may add that at this convocation the Registrar gave the following figures as the result of the work of the University since its foundation:—Candidates passed matriculation, 5779 ; B.A., first examination, 911 ; second examination, 1458 ; M.A., 172 ; B.Sc. first examination, 94 ; second, 75 ; D. of Sc. 9 ; B.L., first examination, 16 ; second, 193 ; D.L., 22 ; B.M., preliminary scientific examination, 362 ; first examination, 785 ; second examination, 525 ; M.D., 261 ; B.S., 8.

The British Orphan Asylum.

This Society was first established at Clapham-rise, but in order to receive an increased number of residents, it was removed to Slough, where more commodious premises were obtained. These were opened by His Royal Highness, the Prince of Wales, in June 1863, on which occasion it was announced that a donation of £14,000 was presented to the charity by Mr. Edward Mackenzie, of Fawley-Court. This gave a renewed impetus to the undertaking, and the new buildings were completed four years ago. The institution was founded for the gratuitous reception and education of orphans of both sexes, and all denominations whose parents were once prosperous and lived in any part of the British Empire. There are the children of clergymen, naval and military officers, solicitors, merchants, and highly respectable traders, amounting in all to 108 boys and 67 girls. Many pupils have regained the position in society which, by the death of their natural protectors, they had lost. The 42nd anniversary was held on the 11th of the present month, at the City Terminus Hotel, Cannon-street. The Bishop of Ripon presided, and made a powerful appeal to the rich to support the charity which was greatly in need of pecuniary help. There was a large attendance, and upwards of £1000 were subscribed. The children walked round the room, and a selection of vocal music was performed.

The Aged and Infirm Wards of the Saint Marylebone Workhouse.

New wards have been erected for the purpose of relieving the over-crowded state of the house, and providing more suitable accommodation for the aged and infirm. Of the 1800 inmates at present in Marylebone Workhouse, nearly 1000 are over 60 years of age, and it is for infirm women, whose ages are between 70 and 90, that these wards are provided. The Guardians of St. Marylebone are anxious that their aged poor should be made as comfortable as the rules of a Workhouse will permit. A special dietary is provided for them; the helpless are taken out into the parks in fine weather in Bath-chairs, and all who have relatives or friends have liberal permission to see them, either in or out of the Workhouse.

The care bestowed on these unfortunate people does great credit to the Guardians, and their design has been ably fulfilled by the architect of these buildings—Mr. H.

S. Snell, of 36, Chancery-lane. The builders are Messrs. Manley and Rogers. The ventilating, warming, and sanitary works were confided to Messrs. Potter and Sons.

Royal Medical Benevolent College.

The 15th annual festival of this Institution, founded by the late Mr. Propert, was held last Wednesday evening. Lord Granville presided, and made a noble appeal on behalf of this excellent institution. Subscriptions to the amount of £800 were announced. No institution deserves more hearty support by the profession and the public.

St. Bartholomew's Hospital, London.

What is called the annual "view" dinner of this hospital, took place last Wednesday evening, under the Presidency of the Prince of Wales, who had been present in the morning of the same day at the laying of the foundation stone of new St. Thomas's Hospital, by the Queen. Royalty may therefore be said to have lent abundant countenance to hospital work during the week. This "view dinner" derives its name from the custom long observed by many governors of visiting the wards in the afternoon, a custom which the Prince, who is President of the Hospital, observed by visiting six of the wards before dinner. The usual preliminary toasts having been duly honoured, H.R.H., as President, gave the toast of the evening—"Prosperity to St. Bartholomew's Hospital, and Health and Ease to the Patients." In doing so, the Royal President said :—

"It gives me the greatest pleasure to propose this toast. This hospital, the largest and most ancient of the metropolitan hospitals, was founded in 1123 by Rahere, and was then attached to the Priory ; and on the suppression of the monasteries, in 1544, it had a charter granted to it by Henry VIII., whose portrait occupies the wall on my right. At that time the hospital had only 100 beds, one physician, and three surgeons ; it has now 650 beds, 12 physicians, and 12 surgeons, besides an array of lecturers, dispensers, and other officers. We may regard this as a grand day, and those who have gone through the wards of the hospital will have found everything in good order ; but I once took the officers by surprise, and I came here, in the winter, practically without giving notice. I can assure you I found everything on that occasion in the same condition as to-day—nurses and attendants in their places, and surgeons and physicians punctiliously discharging their duties. I may here advert to the terrible event which occurred in the winter—the Clerkenwell explosion. That showed how well-organized the hospital is, and how admirable its arrangements are adapted to such an emergency. Almost immediately after the explosion as many as 40 patients were safely housed in the hospital, while many had their wounds dressed and were sent away. I came here, and found that the sufferers were receiving every possible attention. Much is, no doubt, due to the unremitting care and supervision of the treasurer ; and if one of the surgeons, Mr. Holden, were not present, I would express my appreciation of his valuable services in terms which, I am sure, many in this room would be ready to endorse. Every one is satisfied of the thorough efficiency of the hospital ; but there is still wanting a convalescent hospital. True, there is the Samaritan Fund, out of which you aid patients when they are dismissed ; but still, when they are nearly well, you wish to send them into the country to recruit their health, so that they may return to their homes thoroughly convalescent. When this question is mooted I shall take the greatest interest, and do all I can to promote the establishment of the additional hospital. I have the greatest pleasure in coupling with this toast the name of the treasurer, and no one will more heartily drink his health than I shall. He has been called upon to act as Treasurer to Christ's Hospital too, and, although he will conscientiously serve it, he will not forget his first love—St. Bartholomew's."

The Treasurer, in the course of his response, mentioned that the income of the hospital was last year exceeded by £4000, that at the time of the Clerkenwell explosion he was prepared, if necessary, to turn the dining-room into a ward, and that a plan was on foot to establish, in conjunction with the Merchant Taylor's Company, a convalescent hospital at an expense of £45,000 for each corporation. He also condemned the taxation of charities.

The next toast proposed by the Royal President was the "Medical Staff," mentioning the names of Dr. F. Farre and Mr. Paget, to the latter of whom H.R.H. tendered public thanks for his care of the Princess of Wales in her late illness.

Dr. Frederick Farre and Mr. Paget responded in suitable terms, after which the "Corporation of London" having been given and responded to, the proceedings were brought to a close.

Edinburgh University.

We alluded last week to the report that a strong party is desirous of conferring the Principalship on some one outside the Medical Faculty. We believe that the candidate favoured by this party is a metaphysician of certain celebrity, at present in India. Could anything be more preposterous ?

Here is Sir J. Y. Simpson, whose discoveries and renown are world-wide, resident in the Modern Athens, and himself one of its greatest lions. The University too, that has so long derived its importance from the Medical Faculty ! Why should not that Faculty receive its just recognition in the person of its head ? Sir James Simpson would confer honour on the University as its Principal.

Mr. Whitworth's Scholarships.

We referred in a previous number of our journal, to Mr. Whitworth's proposed endowment of scholarships for promoting mechanical science. From the documents presented by him to the Lords of the Committee of Council on Education, we copy some of the details which will explain more fully the object he has in view, and the methods of carrying it into effect.

He offers to found 30 scholarships of the annual value of £100 each, to be applied for the further instruction of young men, natives of the United Kingdom, selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and its cognate sciences, with a view to the promotion of engineering and mechanical industry in this country.

These scholarships are to be open to all of Her Majesty's subjects, whether of the United Kingdom, India, or the Colonies, who are not above 26 years of age, and ten are to be competed for and awarded in May, 1869. The candidates must be of sound bodily constitution, and in order to obtain a scholarship must show a satisfactory knowledge of all the following theoretical subjects :—1. Elementary mathematics. 2. Elementary mechanics. 3. Practical plane and descriptive geometry and freehand drawing. With the power to use one or more of the following classes of tools :—*a*, the axe ; *b*, the saw and plane ; *c*, the hammer and chisel ; *d*, the file ; *e*, the forge.

As some time must elapse before this scheme can come into complete operation, he proposes at once to establish 60 preparatory exhibitions of £25 each for youths under 22 years of age, who must undertake to compete for the £100 scholarships, in May, next year, and to place them at the absolute disposal of the governing bodies of the following educational institutions and towns :—

Eight exhibitions to Owen College, and two to the Grammar School, Manchester, the seat of my workshops; three University of Oxford; three University of Cambridge; three University of London; and one to each of the following Universites, Colleges, and Public Schools:— University of Durham, University of Dublin, University of Edinburgh, Watt Institution, Edinburgh; University of Glasgow, Andersonian University, Glasgow; University of St. Andrews, University of Aberdeen, to each of the Queen's Colleges at Belfast, Cork, Galway, Ireland; King's College, London; University College, London; Eton, Harrow, Rugby, Charterhouse, Westminster, Winchester, St. Paul's, London; Merchant Taylors, Christ's Hospital, City of London; Shrewsbury, Marlborough, Cheltenham, Chester, Clifton, Brighton, Liverpool, two to the College of Preceptors, three to the Science and Art Department. The following Exhibitions to be given to artisans only:—Three to the Society of Arts; also one for artisans to each of the following towns:— Birmingham, Bristol, Swansea, and Cardiff, Halifax or Huddersfield, Leeds, Northampton, Sheffield, and if there be any of the above unapplied, they may be given by the Science and Art Department to any other scholastic institution which makes satisfactory arrangements for affording instruction in mathematics and mechanics, freehand and mechanical drawing.

The Lords of the Committee of Council have expressed the great pleasure they shall have "in acceding to Mr Whitworth's request, and giving every assistance in their power in carrying out his patriotic munificence."

St. Thomas's Hospital.

The event of the past week was the laying by the Queen, in semi-state, the foundation stone of the new buildings for this hospital.

The principal objection to the site has been removed by the construction of the embankment upon which the hospital will be erected. Facing the Houses of Parliament, it will be a conspicuous ornament of the river bank.

The construction of the buildings, fronting the Thames on the west, and the gardens of the Archi-episcopal Palace of Lambeth on the east, secure a pleasant view and abundant air for the inmates.

We have only to obtain the removal of the objectionable manufactories in the immediate neighbourhood—bone crushing, potteries, tallow, and size works, &c., to secure a salubrious atmosphere.

The "Lambeth fog" is so well-known, and so offensive to all who have occasion to attend the Houses of Parliament, that we may *hope* they will be made to follow the gas-works, which have been removed elsewhere.

The Medico-Political Association and the Poor-law Medical Officers.

The vigorous efforts made by the Medico-Political Association to improve the condition of the profession, have been fully related in our columns. It will not, therefore, surprise our readers to hear that this Association has determined to take up the cause of the Poor-law medical officers. Last Friday afternoon the executive of the Medico-Political Association held a meeting, to which Dr. Rogers and other gentlemen who have laboured in the cause of Poor-law reform, were invited. The meeting became, therefore, a conference between the Association on the one hand, and the representatives of the Poor-law medical officers on the other. The aggregate meeting of London and Provincial Poor-law Medical Officers announced by Dr. Rogers was brought under discussion, and it was felt that it would be of greater importance were other members of the Profession to take part in it. Accordingly, after a prolonged conference, it was resolved unanimously that the meeting of London and Provincial Poor-law Medical Officers, proposed by Dr. Rogers, be held under the auspices of the Medico-Political Association.

Dr. Rogers and two other gentlemen were thereupon deputed to co-operate with the executive of the Association by forming a joint committee to conduct the meeting, which will be convened for an early date.

The Mecca Pilgrims.

Some anxiety has been expressed lest the crowds of pilgrims this year should meet with our troops returning from Abyssinia, and expose them to the danger of infection. We are glad, therefore, to state that hitherto there has appeared no sufficient cause for this apprehension. The *Patrie*, after reminding its readers that early in April seven vessels, coming from Djeddah, and having on board a large number of Mahommedan pilgrims, arrived at Suez, states, upon the authority of letters from Trieste, dated the 4th inst., that these pilgrims, who belonged for the most part to Bosnia and the Herzegovina, had reached that port from Alexandria. It has been established by the sanitary authorities, after the most careful investigation, that the health of these travellers is excellent, that there has been this year no epidemic disease at Mecca, and that two only of the pilgrims died during the voyage in the Red Sea. The ages of these persons were respectively 87 and 92, and their deaths are attributed to the fatigues of the journey.

Quarterly Return of the Registrar-General.

This important document was forwarded to us some days ago, and we intended to give in our last week's issue an analysis of the particulars it contained, but the press of other matters compelled us reluctantly to postpone it until to-day. The features are such as cannot fail to strike every one who feels any interest in the sanitary condition of the country. The recorded natural increase of the population in the United Kingdom during the three months ending the 31st March, was 102,084. The corrected death-rate of the quarter for the whole kingdom is 2231 per cent. It differs little from that of England and Wales, which is 2234 per cent. The average of the corresponding quarters of the previous ten years is 2576 per cent. The deaths registered in England alone, in the quarter, were 120,095, being 14,000 less than in the same quarter last year. In London the deaths registered were 18,144, being 2323 less than in the winter quarter of 1867, and a lower rate of mortality than that of any other of the twelve large towns of the United Kingdom.

Many reasons might have led to the expectation of an increased death-rate, especially in London. The commercial world had not been relieved of its difficulties, trade in general was by no means good, consequently numbers were out of employment, and most were badly paid. The price of bread and other necessaries augmented greatly the distress of the poor, and hence the increase of pauperism both in-door and out-door in the quarter, as compared even with 1867. And yet, notwithstanding all these apparently unfavourable circumstances, the death-rate was considerably below the average of the same quarter of the ten preceding years. The Registrar-General accounts for this satisfactory bearing of the public health, partly from the favourable state of the weather. "February," he says, "was more like a spring than a winter month, and exercised its beneficial influence on the public health. Easterly winds were of less frequent oc-

currence both in February and March than is usual in those months, and the mean temperature at Greenwich was above the average of 97 years, in each of the three months." Again, he says, "Fever and diseases that attack the juvenile population were less prevalent, or where they prevailed were probably less fatal than usual in many districts that in other seasons had suffered from their ravages." And lastly, the improved sanitary measures which have been adopted and carried out, not only in London, but more or less throughout the kingdom, have doubtless tended very materially to prevent the access of disease, and in nearly all localities to lessen its ravages. The result of these, and, probably, other less evident causes, was "a singularly low mortality."

"In London the deaths from small-pox in the last quarter were 280 against 526 in the same period of 1867; those from measles 452 against 239, from scarlatina 368 against 339; from diphtheria 119 against 102; from whooping-cough 734 against 906; from typhus 514 against 565; from phthisis 2184 against 2369; from bronchitis 2282 against 3144; from pneumonia 1035 against 1150."

There are instances given in the report of violent and fatal attacks of disease traced to contaminated water, and the neglect of other sanitary precautions.

Granular Preparations of Iron with Quinine and Strychnine.

Among the various new remedies brought under our notice by the active pharmaciens of the present day, we have seen two granular preparations which are deserving the notice of the profession. The medicines we here allude to are the granular effervescing citrate of iron with strychnine, and also the citrate of quinine with iron and strychnine.

These salts, to look at, are precisely similar, the granules are perfectly clean, white, and dry, and one teaspoonful of either salt rapidly effervesces when stirred up in cold water, while, at the same time, its solution is complete, and a pleasant draught results.

The proportion of strychnine in ℥j. is gr. 1·32, and of quinine gr. j.

As far as we have yet tried these two medicines, we are able to say that they agree well with a delicate stomach, and the quinine preparation is certainly of decided value in ordinary facial neuralgia, giving very speedy and permanent relief. It seems that the solutions, if allowed to stand, rapidly change, become of a yellowish tinge, and then have an unpleasant highly chalybeate taste, but taken as directed, in effervescence, the flavour is very agreeable.

Vaccinomania.

However we may be disposed to pity and forgive the very numerous class of pathymongers who digest and relish any nonsense in the form of quackery, simply because it is new and not true, we cannot regard as leniently the folly of persons who persist in knocking their vacuous heads against the plainest and most forcible facts, and talking mischievous nonsense when the opportunity of correcting their false judgment is afforded to them. In the whole domain of science there is not a fact more simply and convincingly provable than the efficacy of vaccination in preventing the ravages of small-pox. Theory suggests it, and experience, which cannot err, proves it; and no man whom Providence has spared that form of lunacy known as vaccinomania entertains a doubt on the subject.

If Sir J. C. Jervoise, who bores the House of Commons with his ideas or want of ideas on the subject, is ignorant, he should read; but he certainly has no right to obtrude upon the public his indisposition to correct his want of information, or his blindness to the commonest facts and figures.

On the last day of February the number of London paupers relieved reached 156,650.

The Government have appointed a Commission composed of the Marquis of Kildare, the Rev. Dr. Haughton, Fellow of Trinity College; the Very Rev. Dr. Russell, President of Maynooth; Colonel Laffan, Royal Engineers; Mr. G. A. Hamilton, Secretary to the Treasury; Professor Huxley, F.R.S.; and Captain Donnelly, Royal Engineers, with a view of constituting a separate Department of Science and Art for Ireland, analogous in its constitution to the existing Science and Art Department in London, and of amalgamating as far as possible all existing institutions in Ireland receiving State grants for science or art, and to report on the best means of carrying out this object.

The Gresham Lectures will in future be given at 7 in the evening. The lectures on medicine for this term, by Dr. Thompson, the Gresham Professor, are on May 25th, on the Causes of Disease, illustrated with chemical and physiological experiments; May 26th, Diagnosis; and May 27th, Treatment of Disease.

Another case of a ballet girl's dress catching fire during her performance has occurred, and yet the process of rendering the dresses non-inflammable is still neglected.

The Richardson Testimonial is to be presented this afternoon, at 2·30 P.M., at Willis's Rooms.

The Statham Defence Fund has been paid over to Mr. S. The amount was £329, 15s. 6d.

Dr. Alfred Wiltshire has been appointed a Medical Inspector to the Privy Council.

Next Tuesday there is a conversazione at the Pharmaceutical Society.

We regret to hear that small-pox prevails at Dartmouth.

The fund for the new buildings of the University of Glasgow has reached £106,000.

UNIVERSITY OF LONDON.

On the 13th inst. a meeting of the Chancellor, Vice-Chancellor, and Fellows of this University was held for the admission of successful candidates to degrees. Lord Granville (Chancellor of the University) presided, and there were present many members of the Senate, ladies and gentlemen, the relatives and friends of those who were about to receive degrees, medals, and prizes, also assembled in large numbers.

The Registrar (Dr. Carpenter) read a report stating the number of candidates admitted as graduates and undergraduates during the past academical year.

The graduates who had passed the examinations for the degrees were then presented by the several Professors, and the Chancellor, as he admitted them, delivered to them their diplomas.

We have only space for the names of those in the medical faculty:—

M.D.—John Thomas Arlidge, King's College; Stephen Wooton Bushell, Guy's Hospital; Henry Carnley, Hull and East Riding; Thomas Marsden Edwards, Andersonian Institution; Henry Isaac Fotherby, Guy's Hospital; Ralph Gooding, King's College; George Wallington Grabham, St. Thomas's Hospital; John Pearson Hughes, University College

Charles Kelly, King's College; Henry Colley March, St. Thomas's Hospital; Frederick Barham Nunneley, University College; John Jones Philips, Guy's Hospital; George Henry Savage, Guy's Hospital; Thomas Claye Shaw, King's College; Paul Henry Stokoe, Guy's Hospital; John Williams, University College.

M.B.—Charles Edward Squarey, University College; Joseph Groves, King's College; Edward William Berridge and William James Garrett, St. Bartholomew's Hospital; Oliver Thomas Duke and Henry Morris, Guy's Hospital; Herbert Ray Archer, St. George's Hospital; John Durham Bird, R. Manchester School of Medicine; John Lloyd, Edward Mackey, and William Thomas, Queen's College, Birmingham.

B. Sur.—Edward William Berridge, St. Bartholomew's Hospital.

Those graduates who passed with honours were next presented, and received their certificates:—

M.B.—Marcus Beck, University College, 1st in medicine (scholarship and medal), 3rd. *(æq.)* in midwifery, 4th *(æq.)* in forensic medicine; George Ralph Raine, Guy's Hospital, 2nd in medicine (medal), 2nd in midwifery (medal), 2nd in forensic medicine; John Wickham Legg, University College, 5th in medicine; Charles Berrell, King's College, 6th in medicine, 6th in midwifery, 4th *(æq.)* in forensic medicine; John Cavafy, St. George's Hospital, 7th *(æq.)* in medicine; Henry Franklin Parsons, St. Mary's Hospital, 7th *(æq.)* in medicine, 7th in midwifery; James Sawyer, Queen's College, Birmingham, 11th in medicine; Robert Shingleton Smith, King's College, 1st in midwifery (scholarship and medal), 3rd in medicine; John Reuben Bathurst Dove, London Hospital, 3rd *(æq.)* in midwifery, 7th *(æq.)* in medicine, 3rd in forensic medicine; George Hunt Orton, St. Bartholomew's Hospital, 5th in midwifery, 7th (*æq.*) in medicine; Paul Henry Stokoe, Guy's Hospital, 1st in forensic medicine (scholarship and medal), 4th in medicine, 8th in midwifery.

B.S.—Henry Greenway Howse, Guy's Hospital, 1st in surgery (scholarship and medal); Marcus Beck, University College, 2nd in surgery (medal); John Reuben Bathurst Dove, London Hospital, 3rd in surgery.

Each graduate, to whom a scholarship, medal, or prize had been awarded was next presented.

M.D.—Charles Kelly, King's College, (medal).

M.B.—Marcus Beck, University College, scholarship and medal in medicine; Georgh Ralph Raine, Guy's Hospital, medal in medicine; Robert Shingleton Smith, King's College, scholarship and medal in midwifery; George Ralph Raine, Guy's Hospital, medal in midwifery; Paul Henry Stokoe, Guy's Hospital, scholarship and medal in forensic medicine.

B.S.—Henry Greenway Howse, Guy's Hospital, scholarship and medal in surgery; Marcus Beck, University College, medal in surgery.

The Registrar then read a list of the Undergraduates who had obtained honours:—

FIRST EXAMINATION.

M.B.—Richard Lawton Roberts, University College, exhibition and medal in anatomy; William Richard Gowers, University College, medal in anatomy; John Davies Thomas, University College, exhibition and medal in organic chymistry and materia medica and pharmaceutical chymistry; Richard Lawton Roberts, University College, medal in organic chymistry and materia medica and pharmaceutical chymistry.

Proceedings of Societies.

MEDICAL SOCIETY OF LONDON.

MAY 4TH, 1868.

Dr. RICHARDSON, F.R.S., President, in the Chair.

THE PRESIDENT related a "Case of Fatal Railway Accident," illustrating important points in physiology and medical jurisprudence. He was present at the time when a cry was raised that a person had been decapitated by a passing train; he found at once that complete severance *without the loss of any blood* had occurred just above the level of the shoulders. On discovering the trunk, though at least a minute had elapsed, respiratory movements were observed, and the right side of the heart still pulsated. On proceeding down the line the face was found warm, and with the appearance of life; the irides were faintly contracted to light; then the brain was found entire, perfectly enucleated. Its examination revealed indications of old-standing lesion, which gave rise to the hypothesis of insanity—a hypothesis which was substantiated by the evidence at the inquest.

After some remarks by Dr. DAY,

Deputy Inspector-General BURKE said he was once present at decapitation at Canton. Examining the severed head he saw violent contractions of the muscles below the jaws, which continued for at least twenty minutes.

Dr. LEARED thought that the respiratory movements observed might have been automatic, just as those which occur in the hearts of the lower animals after removal from the organism.

Dr. SEDGWICK made some interesting observations on the results of freezing portions of the brain, particularly showing that section or paralysis of the phrenics will allow the recurrence of respiratory and cardiac acts previously arrested.

Dr. W. H. DAY read a paper "On some points connected with the present aspect of Medicine, and on the existing state of Therapeutics." Though advocating much caution in the reception and promulgation of medical opinions, he deprecated the scepticism which is so rife in the present day. One great reason leading to the support of false theories has been the uncertain utterance of practitioners as to the value of medicines. He illustrated the disbelief concerning the value of mercury by facts attesting its influence for good; and, as an illustration of the causative relation between drugs and recovery from disease, or its manifestations, pointed to opium. He spoke of fashion in therapeutic methods, and instanced the rapid rise and quiet subsidence of opinion respecting the Turkish bath, which, though not a universal remedy, is a useful one. He thought that if physicians adopted a uniform method of research, science would be more directly advanced.

In the active discussion which followed,

Mr. DE MERIC instanced the expectant treatment as now applied to pneumonia and to diseases of the eye—the panacea in the latter case being the instillation of atropine. Present day-surgeons scarcely knew how to bleed. Conservative surgery had shot beyond the mark, and preserved limbs which had the demerit of being useless. Of remedies enthusiastically received but which could not stand the test of time, he thought Lister's artiseplus would form a part.

Dr. LEARED thought he erred in placing therapeutics second to pathology; and Mr. HUNT considered the former to be at its lowest ebb.

Dr. TILBURY FOX and Dr. SYMES THOMPSON were not dissatisfied with the present state of therapeutics, which the latter thought was now beginning to stand on a firm philosophic basis.

Dr. SANSOM considered that the present age had contributed much to the establishment of such a foundation. Among the many bases were the adoption of a supporting plan of treatment—the establishment of hygienic and sanitary measures, which reduced the virulence of type in disease, and diminished the foci of dissemination—the employment of the universal method in investigation—the experimental analysis of the effects of drugs in the normal economy—(Dr. John Harley)—the physico-chemical investigations and deductions of Dr. Bence Jones, and the antiseptic treatment introduced by Professor Polli.

Dr. MEREDYTH considered the absorption and elimination of drugs as questions requiring elucidation.

The PRESIDENT said that the "Expectant Treatment" was one of the heresies of Albrotus, coeval with that of "similia similibus curantur." The age for the advance of therapeutics was now approaching, and it was right that pathology should have had the precedence in point of time.

Dr. DAY, in the course of his reply, quoted some instances of the good effects of bleeding.

SURGICAL SOCIETY OF IRELAND.

APRIL 24TH, 1868.

Dr. ADAMS, President of the College, in the Chair.

MR. H. G. CROLY read the following paper on

WOUNDS OF ARTERIES IN THE VICINITY OF THE WRIST AND FOOT, ILLUSTRATED BY SIX CASES.

Mr. President—Accidental wounds of the arteries in the vicinity of the wrist, palm of the hand, and sole of the foot are of frequent occurrence in consequence of the exposed position of the blood-vessels in those regions. The hæmorrhage is

often alarming, owing to the free anastomosis of the blood-vessels, and may threaten life if not arrested with promptitude. The following quotation from the surgical writings of John Bell in his able article on wounds of the arteries near the wrist, renders any apology on my part unnecessary in bringing the subject under the notice of the Surgical Society this evening:—

"If I do not mistake the importance of this accident, it is a sort of duty to explain it to you still further; for, though the operation of tying the radial or ulnar artery does not range in the catalogue of important operations, along with the trepan and amputation; yet, if I be not deceived, it is more difficult than either, and certainly more frequently required."

WOUND OF THE LEFT RADIAL ARTERY HALF AN INCH ABOVE THE WRIST-JOINT: LIGATURE OF THE VESSEL: RECOVERY.

Case 1.—A. B., aged 56 years, a slater, was working on the roof of a stable when portion of the rotten wood-work gave way, he fell through the roof to the ground and was stunned; he was conveyed at once to the City of Dublin Hospital. I saw him immediately after his admission, and observed an incised wound running obliquely across the course of the left radial artery about half-an-inch above the wrist-joint. The brachial artery was at once compressed, and the patient carried up to bed in the accident ward. By proper treatment he soon recovered from the effects of the "stunning." The pressure having been taken off the main artery the blood at once came *per saltum*, which proved that the radial artery was wounded. The wound having been dried with a sponge I observed an oval *slit* in the radial artery nearly a quarter of an inch in length (evidently produced by a broken slate), and in order to secure the vessel above and below the wound I found it necessary to open on a director upwards and downwards the fascia which covers the vessel. The artery was then detached, and a bent eye-probe passed beneath it, armed with a double ligature; the probe having been withdrawn, and the loop divided, the two ligatures were separated, and the artery tied above and below the *slit*. The edges of the wound were approximated with strips of adhesive plaster, and a roller bandage applied; the hand was placed upon a pillow.

The ligatures came away in the usual time, and the man left the hospital in a few days, the wound being perfectly healed.

WOUND OF THE PLANTAR ARCH: LIGATURE OF THE POSTERIOR TIBIAL ARTERY: RECOVERY.

Case 2.—J. W., aged 22 years, a ship-carpenter, in dealing a blow on a piece of timber, the "adze" slipped and struck him in the sole of the foot, cutting through his boot and inflicting a severe wound five inches in length. Bright blood flowed freely from the wound. A handkerchief was wrapped around his foot, and he was conveyed at once to the City of Dublin Hospital.

On his admission, the resident pupils made pressure on the main artery, in consequence of the alarming hæmorrhage, and applied a compress of lint to the wound and a roller bandage.

I was immediately sent for, and having removed the compresses, which were stained with bright blood, I sponged out the wound, but could not see any bleeding-vessel, as the wound was very deep.

I plugged the wound with lint steeped in turpentine, and applied compresses, a roller bandage firmly from the toes, and placed a pad over the posterior tibial artery in the calcaneo-malleolar space, and another over the anterior tibial artery. The limb was elevated. In a few seconds (the pressure having been taken off the femoral artery) the blood flowed freely from the wound.

I now proceeded to tie the posterior tibial artery behind the inner ankle, as follows:—A semilunar incision was made about two and a-half inches in length a "thumb's-breadth" behind the internal malleolus; the three layers of fascia were divided on a director, and the artery detached from its veins and secured with a ligature. Pressure was then taken off the femoral artery, and not a drop of blood escaped from the wound, which was sponged out, and its edges gently approximated with strips of adhesive plaister. Opium was prescribed.

The ligature separated on the fifth day. The wound in the sole of the foot healed up soon, and the man was discharged from hospital.

WOUND OF THE RIGHT ULNAR ARTERY AND NERVE.

Case 3.—J. P., aged 17 years, was working on the roof of a house, helping a plumber. His foot slipped and his leg went through a skylight. He put out his right hand to save himself from falling, and received a severe wound from a broken pane of glass across the wrist. The wound was semilunar. The blood "spouted" from his wrist. A handkerchief was tied tightly around the wound, and he was conveyed at once to the City of Dublin Hospital.

On admission pressure was applied to the brachial artery, and on examination I ascertained that the ulnar artery and nerve were completely divided.

I secured the upper end of the artery without difficulty; but the *distal* end retracted beneath the fascia, which I divided on a director, and was thus enabled to secure it. The edges of the wound were brought together with iron wire sutures, a compress of lint applied, wadding-cotton wrapped around the hand, and a roller bandage. The patient was placed in bed, and an opiate administered.

He complained of great pain and numbness in the little finger and half of the ring on the following day.

On the fifth day the ligature came off the cardda end, and on the eighth day from the *distal*.

On the fourteenth day the patient was discharged from hospital, the wound having healed.

He presented himself amongst the extern patients in a fortnight subsequently, and said that sensation had returned to the ring finger, but not to the little finger.

A month after the accident he came to the hospital, and I found his little finger swollen, and a large bullæ filled with pus and serum on its posterior aspect, which I opened and ordered to be poulticed.

The case progressed favourably afterwards, but sensation did not return to the little finger.

GUNSHOT WOUND OF THE PALM OF THE HAND AND WRIST—WOUND OF PALMAR ARCH—ULNAR ARTERY AND MEDIAN NERVE—RECOVERY WITH A USEFUL HAND.

Case 4.—M. F., æt. 17 years, page to a gentleman near Dublin, was out shooting; the gun, which was loaded heavily with simple shot, burst into pieces, causing a severe wound of the palm of the hand, wrist, and lower part of the forearm. The hæmorrhage, which was profuse and arterial was controlled by pressure applied to the brachial artery and hand—the patient was sent to the City of Dublin Hospital. I saw him almost immediately after his admission, and noted the case, as follows:—

Patient partially collapsed, and suffering intense pain. On removing the temporary dressings, I observed an extensive lacerated wound extending from the junction of the lower to the middle third of forearm to the centre of the palm of the hand. The muscles protruded, and several divided tendons were hanging loosely. The anterior annular ligament was completely severed, the median nerve divided, and the radial and ulnar arteries were exposed. I examined the wound carefully in order to ascertain if any wadding or portion of the gun had entered, but could not find either. The patient was placed in bed in the accident ward, and took a stimulant and full opiate. When pressure was removed from the brachial artery, several branches of the palmar arch bled. I tied them, and having sponged out all clots from the wound, proceeded to make careful pressure in the palm in the following manner—small bits of lint steeped in the muriated tincture of iron were applied into the bottom of the wound, and then larger pieces over them, so as to make a graduated compress; the surrounding part of the palm was filled with flat compresses to prevent blood being extravasated beneath the palmar aponeurosis; before proceeding further, I was obliged to amputate the ungual phalanx of the *little* finger which was comminuted. I next applied the gantlet bandage (of "Genga"), and placed compresses on the *dorsal* interosseous spaces, to prevent the perforating arteries keeping up hæmorrhage by supplying the palmar arch.

The fingers were next *flexed* on the palm, and fixed in that position with a view of relaxing the palmar fascia, which, if on the stretch, would tend to keep open the mouths of the vessels. I observed a slit in the ulnar artery, about two inches above the wrist, and secured it by passing an acupressure needle under it (carefully avoiding the ulnar nerve), and a loop of inelastic iron wire over it: all hæmorrhage was thus fully arrested. Compresses were applied to the radial and ulnar arteries, and a roller bandage evenly adjusted to the bend of the elbow; another roller was placed transversly in the anticubital fossa, and the forearm flexed on the arm; the battle-door splint, carefully padded, was applied to the hand and forearm to give support.

The anti-tetanic pills of the late Mr. Robert Moore Peile, were prescribed as follows :—

℞ Aloës hepaticæ.
Pulv. antimonialis, aa. gr. xij.
Opii pulverizati, gr. iij.
Syrupi simplicis, q.s.
Ut fiant pil : xij. equales.
ij. ter die sumendæ.

In addition to the anti-tetanic pills, a full opiate was administered each night ; the patient took ice, beef-tea, and wine.

The acupressure pin was carefully withdrawn on the third day without any disturbance of the bandages ; there was no return of the bleeding, and the wound healed gradually ; the boy remained nearly three months in hospital, and was discharged with a useful hand ; he is now able to attend table and drive. I now exhibit to the Society, a photograph of the boy, showing his hand, and I also exhibit the *gun* itself.

COMPOUND COMMINUTED FRACTURE OF THE METACARPAL BONES OF THE LEFT THUMB AND FOREFINGER, WITH WOUND OF THE RADIAL ARTERY, CAUSED BY A CIRCULAR SAW : HÆMORRHAGE ARRESTED BY ACUPRESSURE : WOUND DRESSED WITH CARBOLIC ACID : RECOVERY, WITH A USEFUL HAND.

Case 5.—E. D., aged 70 years, a boatman, incautiously put is hand under a circular saw to pull out shavings. The saw caught his hand, and almost completely severed his thumb and forefinger. He was conveyed to the City of Dublin Hospital, and I saw him at once on admission, as I happened to be in attendance on the engine-driver and stoker of the train who were injured by the serious accident at Bray Head.

On examination I observed his thumb and forefinger lying in the palm of the hand, being held merely by the integument in front, with flexor tendons. A fearful wound presented itself, extending from the palm or side of the ball of the thumb to the dorsal surface of the second metacarpal bone. Arterial blood flowed freely. When pressure was taken off the main artery, which an assistant had charge of, I sponged out the wound and tied several small muscular branches of the radial artery. The main vessel was wounded deeply in the interval between the thumb and index-finger, where it dips into from the deep palmar arch, and was secured by passing a long acupressure pin, slightly curved, under it, and a loop of inelastic iron wire over it.

When the hæmorrhage was controlled I proceeded to examine the fractured metacarpal bones. That of the thumb was fractured obliquely in two places at its centre. I placed the ends in apposition, and having moulded accurately a gutta-percha splint and padded it, I fixed the thumb in a good position.

The metacarpal bone of the index-finger was also comminuted, and I was obliged to remove one loose piece of the bone. The first finger was strapped to the second to give support, and the hand was placed on a battle-door splint, carefully padded to fit the palm.

Carbolic acid dressing was applied to the wound before the bleeding occurred. The anti-tetanic pills were prescribed, and a liberal allowance of wine, beef-tea, and ice.

The acupressure pin was removed in a couple of days. The wound redressed with carbolic acid. The patient had not a single bad symptom, and said he suffered no pain whatever from after his hand was dressed. He was discharged from hospital in six weeks, and attended as an extern patient to have his hand dressed. He is now able to oppose the thumb and forefinger, and make good use of his hand.

I exhibit to the society a photograph of the patient and his hand.

GUNSHOT WOUND OF THE THUMB : AMPUTATION AT THE METACARPO-PHALANGEAL ARTICULATION : RECOVERY.

Case 6.—C. H., aged 25 years, groom to a nobleman near the city, was out shooting. He placed his thumb on the top of one of the barrels of the gun. The breech was on the ground. From some unexplained cause the gun went off, the shot carrying away the ungual phalanx of his right thumb. He lost a considerable quantity of blood, and was conveyed to the City of Dublin Hospital.

On examination I found the ungual phalanx hanging loosely. The bone of the second phalanx was shot away, and attached to the ungual phalanx only by integument.

I made a flap of the sound integument, and covered the head of the metacarpal bone. The vessels were acupressed, and the wound dressed with carbolic acid. The anti-tetanic pills were prescribed, and a full opiate administered.

The patient suffered considerably from pain at the arm for the first few days. The wound gradually healed, and no bad symptom occurred. He was discharged from hospital.

The photograph which I exhibit shows well the stump after recovery.

Dr. FLEMING observed that the ingredients of the anti-tetanic pill, as mentioned by Dr. Croly, were correct ; but the proportions were not those which he had been in the habit of using. Instead of antimonial powder, tartar emetic was generally used if the individual was strong and healthy ; but if he were old or asthenic, then the antimonial powder was used. The pills were only used in those cases where the wound was such as rendered it not unlikely that tetanus might occur. They were constantly had recourse to in cases of critical and serious operations. The usual dose in which he had administered opium was a quarter of a grain ; tartar emetic, one-eighth of a grain; and a quantity of aloes. One ingredient, he was glad to see, was omitted, and that was calomel, which he had often heard noted, as if it were one of the original ingredients of this pill. The cases brought forward by Mr. Croly were of extreme interest, and had been very successful indeed. All surgeons knew that injuries of the thumb, of the sole of the foot, and in the vicinity of the ankle-joint—injuries involving any of the vessels—were very frequently followed by inflammation of a semi-diffused character ; and after the deligation of arteries in these special localities, it was very likely that some inflammation would intervene, of a more or less diffuse character. It was fortunate that such a contingency did not happen in any of the interesting cases brought forward by Mr. Croly. He had alluded to some cases described by Mr. Bell. It was a long time since he (Dr. Fleming) had read the title of these cases ; but he had recently met with a book in which a number of those cases of wounds involving the radial arteries, the palmar arteries, and the ulnar arteries, and accompanied by very profuse hæmorrhage, were described—viz., "White's Cases in Surgery," published 50 or 60 years ago. The means Mr. White adopted to stop the hæmorrhage, when the wound in the artery lay open before him, was to place a piece of dry sponge in it, and this plan had been adopted with great success.

The PRESIDENT asked, was it a perfectly naked sponge, or covered with anything.

Dr. FLEMING replied that it was a piece of bare sponge, but Mr. White took care to remove it at a particular period.

The PRESIDENT—Do you approve of separating the edges of the wound by thrusting a piece of naked sponge into it, instead of drawing the edges together and using a compress ?

Dr. FLEMING—No.

The PRESIDENT observed that Dr. Croly was for active surgery in these cases, but he in many cases would prefer to follow a different procedure, by first trying the closing of the wound and using pressure, which in many cases will save the necessity of further interference.

Dr. FLEMING said he was an advocate of bringing together the edges of the wound, and some pressure. He was quite opposed to separating the lips of the wound, and to the unnecessary deligation of the arteries, without first having recourse to the ordinary means of pressure.

Dr. EDWARD HAMILTON said there was one important matter which should be borne in mind—namely, the amount of injury to the part from which the hæmorrhage proceeded. If they had a free, open, and exposed wound, with hæmorrhage from that wound, the simplest course for the surgeon was to tie the vessel above and below the wound in it. He thought in other cases, such as wounds in the palm of the hand, arising from simple puncture, when they had sound tissues to deal with around the wound, they should treat them by compression. If, however, they had much laceration it was often difficult to discover the part where the vessel was wounded. When the parts around the wound were injured by contusion they would not bear pressure so well, and they were then obliged to stop the hæmorrhage by tying or twisting the artery.

Dr. CROLY said that Mr. Bell cautioned the surgeon against using the sponge, and mentioned cases where the arm had afterwards to be amputated because of the consequences which arise from the adoption of this method of stopping a hæmorrhage. He should therefore be very careful of using a sponge. In the six cases which he mentioned, the blood was spouting in his face, and he felt it necessary to adopt active surgery, and he was successful. Mr. Bell said that when the artery was tied securely, the surgeon was freed from anxiety, but when closed by other means the hæmorrhage was liable to return. A man came to the City of Dublin Hospital, with a wound by a chisel in the

ulnar artery. The resident pupil put on a compress, and treated him as well as most surgeons would treat him. He saw the man the next day, with his hand in the bandage. He would not stir the bandage, but advised him to stay in the hospital. He refused, however, to do so, and in six days afterwards the wound broke out again. It was then found a very difficult matter. to tie the artery.

(To be continued.)

Correspondence.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND ITS CHARTER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The time is fast approaching when the state and condition of our College is to be set forth in the annual report of the Council, and yet no rumour has reached us of any deliberation on the important subject of a new charter. I am the more surprised at this, as a strong feeling exists outside the council chamber, that our present charter has grown obsolete; that under its provisions we have drifted into some remarkable anomalies, and that so long as we are fettered by its restrictions, we will be unable successfully to compete with rival institutions, so quickly cropping up about us. The first of these anomalies is one which I approach with much reserve, and will dismiss very briefly, as anything which I may urge respecting it will naturally be set down to motives of self-interest, I allude to the connection between the College and its school. Some years ago when this subject was discussed by the College at large, we were told that the birth of the school preceded that of the College, and that really the College was an appendage to the School. This state of things may have been admissible in the infancy of surgical science, when the means of teaching surgery were extremely limited, but I question if it is either necessary or expedient, in the present day, that the School should exercise so preponderating an influence in the deliberations and proceedings of the College, or absorb so large an amount of its revenues. The second anomaly to which I would direct attention, is the general arrangement of our Court of Examiners. Under our present charter lecturers in schools—men highly qualified for the office, are excluded from the post of examiners, and thus the body from whom the examiners are chosen is necessarily very limited, and these appointments become vested in a few individuals. Hitherto, no doubt, we have been able from this small body to select a sufficient number of gentlemen of undoubted ability, high professional attainments, and unblemished honour and integrity, but in the event of vacancies I hardly see how their places are to be supplied. In the present condition of affairs this provision of the charter is a glaring absurdity. I take it for granted that the rule was adopted in order that there being no relation of teaching between the examiner and the candidate, the court should be placed on high ground, above even the suspicion of partiality. This rule, however, does not exclude clinical teachers in hospitals from holding office as examiners, and yet we know that the relation between the clinical teacher in an hospital and his pupils, is as intimate (if not more so) as that of a lecturer in a school. We know that the competition for pupils is just as keen among hospitals as it is among schools. We know that it is a part of the tactics of every hospital to obtain a representative on the Court of Examiners, and we know that students regard with special favour those hospitals which possess this advantage, quite apart from any superiority as fields for clinical instruction, and even attend such hospitals for a short term to learn the peculiar views of such examiners. In fact, the simple principle enunciated by this arrangement is this, so long as a man is a clinical teacher in an hospital, he is to be regarded as a man of honour, and impartial as a judge; but the moment he becomes a lecturer in a school, he is at once placed under a ban—he is branded as one not to be trusted, he is no longer capable of discharging without bias the duties of examiner.

Surely such a tissue of incongruity would not have been so long tolerated in any other institution in the world. Again, it is determined by the existing laws that two Members of Council shall preside as assessors at each examination, and so important a part of the examination is this regarded, that two Members of Council called upon to preside, are stimulated to punctuality by the not very liberal fee of 5s. 3d. Now, some of the Members of Council are not only clinical teachers and lecturers in schools, but even *private teachers*, and although ineligible to sit as examiners, they are called upon to discharge duties paramount to those of examiners. It may be said they take no part in the examinations, but they supervise the examiners, and it should be borne in mind that they are the electors of the individual members of the court. What must be the effect on the mind of a candidate as he sits down to be tested at an examination table, presided over by the clinical teacher of a rival hospital—the lecturer in a rival school, nay more, the *private instructor of a rival class*—it must unnerve him, whatever his attainments may be. I am not now putting an imaginary case, I am simply stating what has occurred, and certainly this state of things does not place the court on that high ground contemplated by the charter.

I cannot leave this subject without protesting against the introduction of aliens to conduct the preliminary examinations. The Fellows of the College ought to be, and are fully competent to undertake all the examinations in the College, and are the best judges of the class of preliminary education most suited for the student: if the remuneration were as liberal as it ought to be there would be no lack of Fellows to seek the office. As I dislike anonymous letters, I beg to subscribe myself.—Your obedient servant, EDWARD HAMILTON.

120, Stephen's-green, 1st May, 1868.

"THE RATIONAL TREATMENT OF CONSUMPTION."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with pleasure, in your last issue, a paper by Dr. Mulvany, on "The Rational Treatment of Consumption." Without either supporting or denying the correctness of his views, I beg to draw the author's attention to what, to my mind, appears an omission on his part.

Dr. Mulvany commences his paper by saying, "Few of the methods of treatment, are advanced on that of rationality." Now, as an exhaustive work has been written by Dr. H. Mac Cormac, on the so-called "Rational Treatment," I submit, in fairness, it should have been quoted. Dr. Mac Cormac's work, second edition, is written on the same ground of inductive philosophy, guided by the best light of physiological science; and he has urged the value of pure air with a strength, a reiterative force, and a variety of illustration, which I question have ever been matched by any other writer. Dr. Mulvany's physiological conclusions are of immeasurable importance; but he will find in the work referred to, a number of cases bearing out his theory. I would particularly draw the author's attention to the "Fifty aphorisms, illustrating the production of tubercle," at the end of Dr. Mac Cormac's work.—I am, dear sir, yours, &c.,

P. M. RICE.

May 2, 1868.

PHOSPHORIC ACID IN THE TREATMENT OF DIABETES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

J. W., æt. 20 years, labouring under diabetes, consulted me in April, 1867, stating that he had been in declining health for some months previously. His condition was then as follows:—

Skin hotter than natural, harsh and dry; pulse 89, soft and full; tongue covered with a thick white fur; bowels obstinately costive, the stools being hard and dry; the urine pale, straw-coloured, having an odour of fresh apples, and of 1053 spec. grav.; Moore's and Tromer's tests showed the presence of sugar in considerable quantity; the thirst was excessive. There was great emaciation, especially of the face, the bones of which stood out with great distinctness, the aspect presented the malignant hue of organic disease; the gait was slow, feeble, and even stooped, so that although he was only a youth, he yet reminded one of an old man.

He complained principally of an inordinate and craving appetite, an excessive thirst, and great muscular weakness and debility; so great, indeed, was the debility, that he was scarce able to go up stairs. His appetite was so unsatiable that he was obliged to carry his pockets full of bread and biscuits, as well as eating a substantial meal five times daily; he could not refrain from eating for more than 15 minutes at once, and his thirst was so excessive, that he was compelled to get up three or four times during the night to drink. During the night he frequently drank twelve pints of water, and during the day it

was his custom to place his mouth under a water-tap and allow it to run until his thirst was satiated. The quantity of urine passed daily was about 16 pints, and so frequently was he obliged to pass it, that it had induced irritation of the urethra. The mind was depressed, the power of attention weakened, and the manner irritable and peevish. The sexual power was almost gone. Owing to these symptoms he was unable to follow his employment. The heart's sounds, however, were natural in character and rhythm, and nothing abnormal could be discovered on auscultation or percussion. Prior to my seeing him he had been under treatment, which consisted principally in the administration of bitter tonics, the use of bran bread and claret wine. The improvement, however, was trifling.

I commenced treatment by giving grs. v. of Pulv. Doveri three times a-day; a full dose (grs. 2½) of opium every second or third night; 25 drops of dilute phosphoric acid in a glass of water thrice daily after meals, and 30 drops of tinct. ferri per chlorid. twice daily before meals. Jalap, podophylline, scammony, and castor oil, were each in turn administered as purgatives. Warm clothing, and entire abstinence from alcoholic liquids, were enjoined. Weak beef-tea and mutton-broth were recommended as drink. Under this treatment the improvement became very marked: the urine became less in quantity and of lower specific gravity, so that he was obliged to rise only once during the night to pass water. The weakness became less, and thirst became considerably abated, but the appetite was not changed, it was still excessive, and craving. He became tired of taking medicine, and also of the monotonous diet, which consisted mainly of beef, bran bread, and mutton-broth; he also gave up taking the Dover's powder and tinct. ferri perchlorid., trusting alone to the dilute phosphoric acid, which was now increased to 30, and ultimately to 35, drops for a dose, which latter had still the effect of keeping down the thirst.

As the appetite was still excessive creosote was tried in various combinations, but owing to its nauseous flavour, the patient was unable to persevere in its use; it had therefore to be discontinued. Sulphate of zinc, tannic, and hydrocyanic acids were tried, but they proved valueless. Cod-liver oil was used for a considerable time, and it seemed to do good; it certainly improved the appearance of the patient. Alcoholic drinks of all kinds, even the claret wine, induced a state of feverishness, and invariably increased the thirst; they were therefore strictly forbidden. The patient himself has the greatest confidence in the dilute phosphoric acid, and continues to take it to the neglect of every other remedy. It has so much improved him, that he now only drinks four pints during the day, and is seldom disturbed during the night, either by having to rise to drink or pass water. The appetite is somewhat, but not materially, lessened; the skin is almost natural, and the bowels tolerably regular; the urine is greatly lessened in quantity, and of specific gravity 1039, ranging occasionally to 1042, and the strength strikingly improved. He has been able to follow his employment during the past six months, and is much more cheerful than formerly.

Now, I do not mean to say that phosphoric acid will cure cases of diabetes, but I believe that it is the principal, if not the only agent by which the thirst in diabetes can be materially lessened. I have observed its beneficial effects in two other cases, and I quite concur with the late Dr. Prout, who, I believe, was the first to introduce it to the notice of the profession; that it is of the utmost use in this inveterate disease. As to creosote, I cannot speak definitely, as owing to its disagreeable taste the patient was unable to continue its use sufficiently long. Tincture of perchloride of iron, Dover's powder, and opium, are valuable medicines in this disease, but any one of them used separately will not produce the same beneficial or striking effects of the phosphoric acid. As for tannic acid, sulphate of zinc, and hydrocyanic acid, I have never been able to discover their beneficial effects; but, on the contrary, I think the two former are productive of mischief by increasing the constipation. As for cod-liver oil I would recommend that it should get a fair trial in every case. Perseverance and self-control must be inculcated on every patient, without which success in treatment can never be attained.—I am, sir, yours, &c., J. G. THORNLEY, M.D.

Medical News.

UNIVERSITY COLLEGE, LONDON.—The prizes in the Faculty of Medicine for the winter term of 1867-8 were distributed on the 12th instant, in the presence of a large number of the relatives and friends of the students, the Right Hon. H. A. Bruce, M.P., presiding.

The following prizes were distributed:—

CHYMISTRY (Professor Williamson, Vice-Dean).—Gold medal, E. B. Aveling, of London; 1st silver medal, Sidney Coupland, of Streatham; 2nd silver medal, E. J. Ramsey, of London; certificate—4th, equal, Edward A. Schafer, of Highgate, and Walter Cornelius, of London; 5th, M. A. Tarkadakar, of Bombay; 6th, Edward J. Emanuel, of Southsea; 7th, W. H. Johnson, of London; 8th, W. Ottley, of Pau.

ANATOMY AND PHYSIOLOGY (Professor Sharpey, M.D., F.R.S.)—Gold medal, Rushton Parker, of Liverpool; 1st silver medals, equal, J. H. Mummery, of London, and Charles H. Carter, of London; certificates—4th, E. R. Edger, of Uxbridge; 5th, W. Wynn Westcott, of Martock; 6th, Edwin Rickards, of Lutterworth; 7th, equal, Harry Maule Crookshank, of Cheltenham; Frederick P. Johnson, of Jersey; and Howell Rees, of Maesteg.

ANATOMY (Professor Ellis, Senior Class).—Gold medal, H. N. Martin of Welshpool; 1st silver medal, Alfred Shewen, of Sevenoaks; 2nd silver medal, Rushton Parker; certificates—2nd, Leonard Cane, of Kensington: 3rd, E. R. Edger,; 4th, E. B. Aveling; 5th, J. Magrath, of East Grinstead; 6th, Walter Cornelius.

MEDICINE (Professor J. Russell Reynolds, M.D.)—Gold medal, Tempest Anderson, of York; 1st silver medal, John Bolton, of the Mauritius; 2nd silver medal, E. W. Symes, of London; certificate—4, Charles Wood, of London.

SURGERY (Professor Marshall, F.R.S.)—Gold medal, Tempest Anderson; 1st silver medal, A. J. H. Crespi, of Cheltenham; 2nd silver medal, John Bolton; certificates—4th, equal, William Bishop, of Chipping Norton, and Alfred H. Hackney, of London; 6th, Charles Wood; 7th, William Milligan, of Buxton.

COMPARATIVE ANATOMY (Professor Grant, M.D., F.R.S.)—Gold medal, Alfred H. Carter, of Pemsey; certificates—2nd, E. M. Swanwick, of Manchester; 3rd, E. A. Schafer; 4th, R. N. Godlee, of Upton; 5th, William Hardman, of Blackpool; 6th, William Ottley, of Pau; 7th, J. A. W. Wardale, of Newport; 8th, W. G. Watson, of Sydney.

PRACTICAL PHYSIOLOGY AND HISTOLOGY, Senior Class (Michael Foster, M.D.)—Silver medal, R. T. Smith, of Hebdenbridge; certificates—2nd, J. H. Mummery; 3rd, Rushton Parker; 4th, Charles H. Carter; junior class—certificate, Edward B. Aveling.

FELLOWS' CLINICAL MEDALS.—Senior Class—Gold medal, J. G. E. Bolton; silver medal, John Davies Thomas, of Swansea. Junior class—Silver medal, T. Llewelyn Brown.

PROFESSOR ROSCOE AT APOTHECARIES' HALL.—The third of Professor Roscoe's lectures on Spectrum Analysis was delivered on Saturday afternoon, and illustrated by numerous experiments, which produced enthusiastic applause. The lecturer related the circumstances under which new elements had been discovered by means of spectrum analysis, and paid his tribute of respect to most workers in this field—Talbot, Herschel, Bunsen, Kirchhoff, and others. He then described the history and properties of cæsium, rubidium, thallium, and indium. He exhibited the spectrum of each upon the disc, and after that the spectrum of mineral waters containing some of these elements. A description of the construction of spectroscopes closed this interesting lecture.

SCIENCE AND ART FOR IRELAND.—Her Majesty's Government, with a view of constituting a separate department of science and art for Ireland, analogous in its constitution to the existing Science and Art Department in London, and of amalgamating, as far as possible, all existing institutions in Ireland receiving State grants for science or art, have appointed a Commission to report on the best means of carrying out this object. The Commission will be composed of the following gentlemen:—The Marquis of Kildare, the Rev. Dr. Haughton, Fellow of Trinity College, Dublin; the Very Rev. Dr. Russell, President of Maynooth; Colonel Laffan, Royal Engineers; Mr. G. A. Hamilton, Secretary to the Treasury; Professor Huxley, F.R.S.; and Captain Donnelly, Royal Engineers, who will also act as secretary.

WHOLESALE CIRCUMCISION.—A Constantinople journal announces a circumcision on a great scale as about to take place at Kanelili. The son of Mustapha Fazil Pacha is about to undergo the initiatory rite of his religion, and 500 boys—the children of parents in reduced circumstances—are to be treated to it at his highness's expense. It is computed that the ceremony will last five days, the surgeons being unable to finish off neatly more than one 100 patients a-day; and that it will cost upwards of £5000. Presents are to be made to the parents of the circumcised, and the whole party are to be lodged and fed until their wounds are healed.—*Pall-Mall Gazette.*

DR. JOHN GIBSON FLEMING has been re-elected Representative of the Faculty of Physicians and Surgeons of Glasgow, in the General Medical Council.

THE Fund for the Royal Infirmary of Edinburgh already exceeds £50,000.

Dr. LETHEBY'S

FOURTH LECTURE ON FOOD.

PRESERVATION OF FOOD.—UNWHOLESOME AND ADULTERATED FOOD.

(Continued from page 434.—Conclusion.)

AND now, in conclusion, let me make a few remarks on the subject of the *fraudulent sophistications of food*—a subject which has been very popular for the last fifty years, or rather, I should say, since the year 1820, when Mr. Frederick Accum published his treatise on "Adulterations of Food, and Culinary Poisons," with the startling motto from the Book of Kings—"There is death in the pot." As you may easily imagine, such a terrible announcement by a well-known writer, could not fail to excite alarm in the public mind, and to provoke anxious curiosity. The book, therefore was eagerly sought for, and a thousand copies of it were sold within a month of its publication; so that, to use the words of the author, in his advertisement to the second edition—"there was sufficient inducement to reprint the work." The singular success of Accum's undertaking has been such a temptation to others, that the press has literally groaned with the efforts of sensational writers on this subject. And although I am ready to admit the importance of it, yet I am bound to state that it has often been grossly exaggerated, especially by those who have had but little practical knowledge to guide them.

The objects of fraudulent adulterations of food are three-fold:—

1. To increase the bulk or weight of the article.
2. To improve its appearance.
3. To give it a false strength.

Among the first of these adulterations are the following:—

(a) The addition of *inferior starches*, as potato-starch or English arrow-root, curcuma or East Indian arrow-root, jatropha or Brazillian arrow-root, tacca or Tahiti arrow-root, canna or Tous-les-mois starch, sago-meal, &c., *to true maranta, or West Indian arrow-root*—of which Bermuda arrow-root is the most esteemed variety. A microscopic examination of the starch or fæcula will always discover the fraud.

(b) The mixture of *starch-sugar* or even *starch* itself *to common cane-sugar*. Starch-sugar, or as it is sometimes called, grape-sugar, or glucose, is manufactured both in this country and on the Continent to a considerable extent. It is made from any description of starch, by boiling it for half-an-hour or so in water, containing about one per cent. of sulphuric acid. The acid is then neutralized with chalk, and the liquor evaporated to a density of 1·28. While hot, it is run off clear from the insoluble precipitate of sulphate of lime, and on standing in a cool place for a few days it crystallizes or sets into a solid mass. This description of sugar has a low sweetening power—not half so great as that of cane-sugar—in fact it is produced from the latter by the action of vegetable acids and heat, when cane-sugar is added to fruit in making a tart or fruit pie, and in making jellies and jams. It is false economy, therefore, to sweeten to any extent before the tart is baked. The sugar is known by many characters, as a want of sparkle from the absence of well-formed crystals; its less solubility in water, and greater solubility in alcohol; and by its giving a deep port-wine tint to a solution of potash, when it is boiled with it.

(c) The dilution of *milk*, *vinegar*, &c., with *water*. This fraud is easily detected by the specific gravity of the liquid, and in the case of milk by the proportion of cream in the lactometer, and by the poor appearance of the milk when under the microscope.

(d) The mixture of *dripping* and *other fats* with *butter*, and *water* and *starchy* matter with *lard*. Butter and lard should always furnish, when melted, a clear looking oil, with but little deposit of water or other substance.

(e) The addition of *gelatine* to *isinglass*, which is sometimes so well managed that it requires a skilful analysis to detect it. Isinglass is an organised substance, and, when examined with the microscope, exhibits a peculiar structure which is very characteristic of it; not so, however, with gelatine. A particle of isinglass put into cold water remains opaque, like a piece of white thread, and does not swell out; whereas, gelatine becomes transparent, and enlarges a good deal in bulk. Jelly made from good isinglass has a slightly fishy smell, and is neutral to test-paper, but that from gelatine has a distinct odour of glue, and an acid reaction. Lastly, if a few grains of isinglass be burnt in a metal spoon until the ash alone remains—the ash will be very small in quantity, and of a reddish colour, while

that of gelatine will be much larger in amount, and of a white appearance. Gelatine never agrees with the delicate stomach of an invalid like isinglass; and, therefore, it is often important to discover the difference.

(*f*) *Coffee* adulterated with *chicory*, is readily detected by sprinkling the mixture upon water, when the coffee, which is slightly greasy from volatile and fixed oil, floats, while the chicory sinks, and gives a brownish tint to the water. The experiment is easily made, as you here see, in a tumbler of water, and you may, with a little tact, determine the proportions of the mixture.

(*g*) *Wheaten flour* is frequently added to *flour of mustard*, and when the quantity passes beyond a certain amount, it is undoubtedly an adulteration, for the intention of it should be only to reduce to an agreeable extent the pungency of the mustard.

Of the second class of adulterations, where the object is to *improve the appearance of the article*, there are many examples, as :—

(*a*) The addition of *alum* to *bread*, by which, as I have already explained, inferior, and even damaged, flour may be made into a tolerable looking loaf. It is the property of alum to make the gluten tough, and to prevent its discolouration by heat, as well as to check the action of the yeast, or ferment upon it. When, therefore, it is added to good flour, it enables it to hold more water, and so to yield a larger number of loaves; while the addition of it to bad flour prevents the softening and disintegrating effect of the yeast on the poor and inferior gluten, and so enables it to bear the action of heat in the process of baking. According to the quality of the flour will be the proportion of alum, and hence the amount will range from 2 oz. to 8 oz. per sack of flour. These proportions will yield from 26 to 35 grains of alum in the quartern loaf, quantities which are easily detected by chemical means. Indeed, there is a simple test by which much smaller quantities of it may be readily discovered. Infusion of logwood, as you here perceive, acquires a rich purplish carmine, or claret tint, when it is brought into contact with alum; you have, therefore, only to dip a slice of the bread for an instant, as I am now doing, into a weak, watery, solution of logwood, and if alum be present the bread will speedily acquire a purple, or reddish purple, tint. I have already described to you the other properties of good bread, as that it should not exhibit many black specks upon the upper crust; it should not become sodden and wet at the lower part by standing; it should not become mouldy by keeping in a moderately dry place; it should be sweet and agreeable to both taste and smell; it should not give, when steeped in water, a ropy acid liquor; and a slice of it taken from the centre of the loaf should not lose more than 45 per cent. by drying.

Sulphate of copper is found to act like alum in improving the appearance of bread; and according to Kuhlmann, Chevallier, and others, it is commonly used by the bakers of the Continent, notwithstanding the severe penalties attached to it. In this country, however, it is but rarely employed.

(*b*) *The bloom, or glaze, or facing*, of green and black tea is generally artificial. In the case of green-tea, it is ordinarily a mixture of Prussian blue, turmeric, and sulphate of lime, or China clay; and in that of black-tea it is not unfrequently a coating of black-lead. The tea prepared for the English market is notoriously subject to these adulterations; and it seems that it arises entirely from our own fancy, and not from any desire on the part of the Chinese to pursue such a practice. The adulteration is easily discovered by shaking the tea with cold water, and then straining through muslin, and allowing the fine powder to subside.

(*c*) *Pickles* and *preserved fruits* are often made green with a salt of copper, it being the peculiar property of that metal to mordant, or fix in an insoluble form, the green colouring matter or *chlorophyll* of vegetables. If, therefore, the pickling operation is conducted in copper vessels, or if a little verdigris or sulphate of copper is added to the vinegar in which the vegetables are boiled, the colour of them will be retained. In some cases the quantity added has been so large as to give a coppery look to a steel-fork or knife plunged into the pickle. In such cases, and as might be expected, severe symptoms of poisoning have been occasioned by it.

(*d*) *Ferruginous earths*, or *red oxide of iron*, is frequently added to sauces, to anchovies, to cocoa preparations, and to preserved or potted meats, to improve their appearance.

(*e*) *Mineral pigments*, often of a poisonous nature, are used in colouring confectionary.

And lastly, with the view of giving a *false strength to the article*, we have instances of *sulphuric acid* added to *vinegar*, *black-jack* or burnt sugar to *coffee* and *chicory*, *catechu* or *terra japonica* to *tea*, *cocculus indicus* to *beer*, *cayenne* to *peppers*, &c.

That many of these sophistications are dangerous there can be no doubt, and all of them are frauds on the public. Parliament has therefore attempted to deal with the matter by legislation, as in the "Act for Preventing the Adulteration of Articles of Food or Drink" (23rd and 24th Vic., cap. 84) of 1860; but as the act is only permissive, little or no effect has been given to it. Even in those places, as in the city of London, where it has been put into operation, and public analysts have been appointed, no good has resulted from it; in fact, it stands upon the statute-book as a dead letter. Speaking for the city, I may say that every inducement has been offered for the effective working of the act, but nothing has come of it. In olden time, the remedies for such misdemeanours were quick and effectual. In the *Assisa panis*, for example, as set forth in *Liber albus*, there are not only the strictest regulations concerning the manner in which the business of the baker is to be conducted, but there are also the penalties for failing in the same. "If any default," it says, "shall be found in the bread of a baker of the city, the first time let him be drawn upon a hurdle from the Guildhall to his own house, through the great streets, where there be most people assembled, and through the great streets, which are most dirty, with the faulty loaf hanging from his neck; if a second time he shall be found committing the same offence, let him be drawn from the Guildhall, through the great street of Chepe, in manner aforesaid, to the pillory, and let him be put upon the pillory, and remain there at least one hour in the day; and the third time that such default shall be found, he shall be drawn, and the oven shall be pulled down, and the baker made to forswear the trade within the city for ever." It further tells us that William de Stratford suffered this punishment for selling bread of short weight, and John de Strode for making bread of filth and cobwebs. One hoary-headed offender was excused the hurdle on account of his age and the severity of the season; and it would seem that the last time the punishment was inflicted was in the sixteenth year of the reign of Henry VI., when Simon Frensshe was so drawn. A like punishment was awarded to butchers and vintners for fraudulent dealings; for we are told that a butcher was paraded through the streets with his face to the horse's tail, for selling measly bacon at market, and that the next day he was set in the pillory, with two great pieces of his measly bacon over his head, and a writing which set forth his crimes. In the judgments recorded in *Liber albus* there are twenty-three cases in which the pillory or the thew were awarded for selling putrid meat, fish, or poultry; thirteen for unlawful dealings of bakers, and six for the misdemeanours of vintners and wine-drawers. Of a verity we have degenerated in these matters.

And now, in conclusion, having directed your attention to the nutritive values of different kinds of food; to their functional and dietetical powers; to the modes in which they are associated; to the quantities required for ordinary labour; to the manner in which they are digested; to the effects of culinary and other treatment; to the way in which they may be preserved; and to the causes of their unwholesomeness, we may finally ask if any great generalizations can be deduced from our inquiries?

In the first place, you will, I think, have observed, that there are very striking evidences of design in the way in which organic matter is constantly kept in motion, for, whether living or dead, it is always in a state of molecular activity—either advancing towards the highest state of organization, or retreating to the confines of the mineral kingdom. The result of this is that, with a comparatively small amount of material, and with but little expenditure of force, the work of the living world is fully and effectively performed. Starting from the mineral kingdom, as carbonic acid, water and ammonia, the elements of organic nature pass through a succession of changes, first in the vegetable and next in the animal, until they reach the summit of organization, when they again return to their primitive condition. In this manner a never-ending round of change is perpetuated, and the same material, and the same force are kept moving in the same continuous circle. Through the efforts of the plant the crude materials are formed into vegetable acids, sugar, gum, starch, fat, albumen, and tissue; and then the animal converts them into higher forms of structure, as into gelatine, muscle, and brain; the two extremes, therefore, of these changes are, to use the words of Gerhardt, carbonic acid, water, and ammonia at one end; albumen, gelatine, fat, and cerebral matter at the other—but the transitions to these extremes are countless, and are, as yet, beyond the reach of science. Broadly, however, we may say that the chemical functions of the plant are those of reduction or deoxydation, whereby carbonic acid and water are deprived of their oxygen, and moulded with nitrogen into food; while those of animals are of an opposite nature, for they destroy this food by oxydation. The plant, therefore, is the machine or medium whereby carbonic acid, water, and ammonia, are converted into new compounds, and light and heat are transformed into chemical affinity; and the animal is the medium or machine whereby these compounds are destroyed, and their affinities changed into other manifestations of force, and finally into heat. In this way the circuit of change is completed, and it is not, therefore, difficult to trace the phenomena of vitality to the cosmical forces which the plant had imprisoned. But shall we ever be able to follow through all the intricacies of change, the countless transitions of both matter and force in their passage from the mineral kingdom to the animal, and then back to the mineral again? It is easy to connect, by a correlation of force, the muscular movements of the animal body, and even the highest efforts of the human mind, with the sunbeam which the plant had arrested; but shall we ever be permitted to unravel those mysterious functions which constitute the phenomena of life? Why is it, for example, and how comes it that the living cell of the plant is able to aggregate mineral matter in opposition to the common laws of affinity, and can transform light and heat into cell-force? How is it, too, that the animal in reversing the process, and so restoring the play of affinity, is able to transmute it into other manifestations of force? At present, the utmost we can say of it is, that organic matter is the appointed medium of all these changes, and is designed for the exhibition of vital phenomena, just as mineral matter is the appointed medium for the phenomena of electricity and magnetism; and yet to some extent, perhaps, we are able to penetrate the mystery; for by finding the clue to the peculiar action of the vegetable in reducing chemical compounds, we can, by operating on such substances as carbonic acid, water, and ammonia, produce a large number of organic principles: in fact, of the three great classes of alimentary substances, to which I have so frequently directed your attention—namely, the oleaginous, the saccharine, and the albuminous—it may be said that the first is already within the manufacturing power of the chemist, and the second is nearly within it: so that there is abundant proof that the agency of a vital force is not necessary to the formation of organic compounds, and there is even hope that the fabrication of food may not be altogether beyond the capabilities of man.

Original Communications.

ON THE TREATMENT OF DISEASES OF THE SKIN.

By J. L. MILTON,

SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

CHAPTER II.—SQUAMÆ.

(Continued from page 264.)

B. Pityriasis.—A loosening and falling of the epidermis in the form of minute, branny scales, accompanied by more or less itching, and sometimes in recent cases by heat and redness. Divisions—1. P. simplex, or that just described, generally seated on the head, but may also assail the beard, eye-brows, &c. 2. P. rubra, in which, besides these symptoms, the true skin is inflamed. May attack all the surface. 3. P. versicolor, in which irregular shaped patches appear on the skin, sometimes almost of the colour of a withered leaf, again of a dirty clay tint; generally beginning on the front and middle part of the chest, or in the arm-pits, accompanied at times by fine desquamation, and a good deal of itching.

Mr. Wilson has incorporated pityriasis with his group of eczematous affections, and I think there can be little doubt that pityriasis is often arrested eczema; long ago I called attention to the fact that both tinea circinata and tinea favosa bore a close analogy to eczema, and were capable of passing into it.

All forms of pityriasis, and especially the two first, are in the majority of cases connected with considerable disorders of the health: in one person assuming the form of weakness, lassitude, and weariness; in another of furred tongue, foul breath, loss of appetite, &c.; a third person may suffer a good deal from indigestion and biliousness; a fourth may be labouring under oxaluria, &c. Now, there need be little hesitation observed about saying, that when any of these symptoms are present in an advanced stage, and very often when they exist to only a trifling extent, local treatment will be of little avail, and special treatment of no use at all. The first thing, therefore, is to attack them with their appropriate remedies: citrate of iron, with an ample addition of lemon-juice, a mineral acid, such as the dilute nitric, or aromatic sulphuric, acid in some bitter infusion or tincture, the action of which is often greatly aided by the use of small doses of mercury, such as four or five grains of grey powder taken three or four times a-week, or a grain of blue bill with an equal quantity of acetic extract of colchicum, taken every night. It often happens that such disorder of the health is so slight as not to require the continuance of those remedies more than two or three weeks, but I believe patients are always better for a course of them.

When this has been done a long steady course of arsenic in small doses may be prescribed with every hope of benefit. Bichloride of mercury given daily to the extent of one-eighth, or one-quarter of a grain, is an extremely useful adjunct. The nitric oxide of mercury may be applied every day in the form of ointment. The ointment should be thinned down with a little spirit of wine, or glycerine may be added. When the disease is seated on the head it is always best applied by another person, as the patient will smear the greatest part of the ointment on the hair, thus causing an unnecessary amount of dirt and discomfort without doing any good. I beg, however, it may be understood that I do not take upon me to say the nitric oxide ointment is the best, but that it is the ointment from which I have derived the best results; indeed, it is the only one, the action of which I have been able to examine with such care as would justify me in giving an opinion; the only similar preparations with which I have compared it are those of the chloride of mercury, the ammonio-chloride, and the yellow nitrate.

In pityriasis versicolor, unless there be any marked disorder of the health, the solution of arsenic may be at once

begun with, and given till a distinct impression is made upon the disease; should there be any disorder of the health, it will be absolutely necessary to set this right, for it is of no use giving arsenic till the stomach is in a fit state to bear it. So soon as the patches begin to grow paler under the influence of this potent mineral, local means may be put in operation. One of the best that I know is strong tincture of iodine, made by adding, at least, a scruple of iodine to an ounce of the ordinary tincture; this may be painted on the surface with a glass brush three or four times a week. The sulphur-bath, taken once a week, is also a valuable remedy, but it is so often impossible to obtain it that the recommendation is almost nugatory.

For general pityriasis, as also for that rare form known as red general pityriasis, Mr. Startin gives demulcent and slightly diuretic medicines. His external treatment is directed towards soothing irritation, being principally demulcent baths, such as glue in solution, linseed mucilage, milk, yolk of egg, bran liquor, or quinæ-seed gruel, thinned down with water. He also prescribes mild alkaline baths, and follows these up with the sulphur-fume bath. For local pityriasis, Mr. Startin gives aperient chalybeates and small doses of bichloride of mercury, aided by lotions of borate of soda, by the sulphur-fume bath, and by creosote ointment. For pityriasis nigra, he prescribes lotions of bichloride of mercury, dissolved in a small quantity of hydrochloric acid. When the head is the seat of the disease, Mr. Startin advises that it should be washed every third morning with yolk of egg and tepid water. He is entirely opposed to the use of soap. Mr. Wilson, for red general pityriasis, gives nitro-muriatic acid with a bitter, citrate of iron and quinine and phosphate of iron. Externally he has found the best results from warm baths, used daily, and prolonged for an hour or more. The whole affected surface is afterwards smeared over with benzoated oxide of zinc ointment. He says pityriasis capitis, or rather erythema capitis, invariably yields to an application composed of one part of red precipitate ointment and three of lard, or to the white precipitate ointment diluted in the same proportion. For pityriasis versicolor, Mr. Wilson recommends a lotion containing half-an-ounce of hyposulphite of soda, and half a drachm of carbolic acid to the eight ounces. M. Hardy treats pityriasis of the scalp with soap and water, and a solution of carbonate of potass, afterwards using an ointment of one part of sulphur to thirty of lard, or one gramme of nitric acid to thirty of lard.[1] When the disease occurs in old people, Dr. Frazer uses a weak solution of tannin in glycerine.[2] When crusts form in children suffering under this complaint, he directs that they should be got off with a wash made of equal parts of spirit of rosemary, or brandy and strong vinegar. In diffuse pityriasis, Dr. Neligan used to prescribe mild mercurials and alkalies, with taraxacum and hyoscyamus; for external use mild gelatinous baths. If the eruption resisted this treatment, he ordered alkaline baths, the patient on leaving the bath being well rubbed over with weak elder flower ointment, containing glycerine. In local forms the dilute citrine ointment was rubbed in. In obstinate cases iodine and arsenic were resorted to. All stimulants were excluded from diet. Dr. Neligan was strongly opposed to the indiscriminate use of stimulating applications, a canon of treatment in which I quite agree. Dr. Jenner uses a solution of bichloride of mercury, four grains to the ounce.

Respecting the contagious nature of pityriasis versicolor, we find, as we might expect, every shade of opinion. Mr. Wilson utterly scouts the idea, and Mr. Startin is, I believe, silent on the subject. Mr. Naylor considers it contagious in, perhaps, one case in ten. Dr. Hillier says nothing about the matter; while Dr. Fox leaves us to infer from what he says that it is contagious beyond all question.

I at once admit that I have given so little attention to the subject that I am scarcely qualified to give an opinion at all. At the same time, I am quite prepared to abide by the consequences of stating that the disease is certainly not contagious as a rule. Beyond all doubt cases will occasionally occur which bear the appearance of having arisen from contagion; but in the great majority of cases nothing of the kind can be made out. And as, in addition to this, it does not matter one straw, practically, whether or not it is contagious, I make no further apology for disposing of the subject so briefly, but content myself with giving the facts of several cases admitted at St. John's Hospital, and leaving the reader to draw his own conclusions. It is, however, to be borne in mind that another series of cases might present a different set of facts.

Out of more than twenty cases noted at the hospital there was no history of contagion in any except two. In the first a father and mother, middle-aged, healthy people, living a short distance from London; their two sons and two daughters were all admitted as out-patients, suffering under this affection, and at least two had it in a very severe form. Another daughter and her husband were also attacked by it, and were admitted about the same time. The disorder was stated by them to have been given by a little girl suffering under the complaint, and who had been staying with the family. The second case was that of a husband and wife, their history being that the husband had had the complaint for a long time and in a severe form at the time of marriage, whereas the wife had never shown a symptom of the complaint till she married, soon after which patches of pityriasis versicolor began to appear on the bosom, front of the abdomen and thighs. At the time they began attending they both had unmistakable symptoms of the complaint in question.

As some of my readers may wish to examine the parasite, I quote from Mr. Naylor's work the recommendation to try the plan suggested by Gudden, of raising a blister on the skin by means of some vesicant, and removing the epidermis. The spores will be seen on the upper surface with mycelium penetrating between the scales of the epidermis.

C. Ichthyosis.—Definition—A dry, harsh, warty or scaly state of larger or smaller portions of skin, attended by change of colour in the affected parts, and extreme deficiency of perspiration; often congenital, unaccompanied by pain. Divisions—1. I. simplex. A general dryness and roughness of the skin, with fissuring of the epidermis, which is of a dirty grey or tawny colour; often beginning early in life. It may assume a very aggravated local form, the papillæ becoming covered with hard, tenacious scales, of a dull greyish-green colour. 2. I. cornea (a form of sclerosis); dry, hard, extremely tense state of the skin, beginning at one spot, and gradually extending all over the body, greatly impeding movement of every kind, attended with diminished warmth and sensation. Very rare; possibly of traumatic origin. 3. I. sebacea. Formation of small, hard, prominent, tenacious crusts, the skin beneath which is red, glazed, and tender. The form of ichthyosis mentioned by Willan and accompanied by the formation of horns, is referred to that head. The porcupine disease is simply a variety of ichthyosis simplex.

Treatment.—For simple ichthyosis Mr. Startin recommends bichloride of mercury and arsenious acid, with alkaline baths, and lotions containing creosote. An instance of the local form of this affection, seated on the cheek, is mentioned by the same author[1] as having been successfully treated by blistering with nitric acid and applying arsenical paste. The disease was to all appearance cured, but a scar remained.

Mr. Wilson recommends cod-liver oil and arsenic, Donovan's solution, frictions with fresh and sweet neat's-foot oil, brisk rubbing with the Indian flesh-glove or keesah, a tepid soap-bath once or twice a week, and the sponge-bath as often. Croton oil or ammonia may be employed in the form of friction; sulphur and potass were given with great benefit in one case mentioned by him. The prognosis Mr. Wilson considers favourable. If we cannot cure

1 Leçons sur les Maladies de la peau. 1860. P. 132.
2 Treatment of Diseases of the Skin. 1864. P. 12.

1 *Medical Times*, vol. xiii.

the complaint, we can restore the patient to tolerable health and comfort.

Dr. Begbie[1] found arsenic fail in the treatment of ichthyosis simplex, though in one case it produced some improvement. Mr. Hunt, on the contrary, has been extremely successful with arsenic. He tells us that after the skin has been for many years so rough and rugged that it scarcely wears a human look, it will become smooth and delicate. In some patients this novel state has been permanent; in others the disease has returned. Still, Mr. Hunt maintains we can always give relief. If even we cannot cure the disorder we can ameliorate it, and at least get rid of the fissures which torment the patient so dreadfully. For external use Mr. Hunt prefers glycerine, with Fowler's solution diluted with water.

Dr. Neligan quotes two cases, published by Professor Banks, of the scaly (or simple) form of ichthyosis which were successfully treated, cod-liver oil being used both internally and externally, vapour-baths were also employed. A flannel dress, thoroughly impregnated with oil, was constantly worn next the skin. Dr. Neligan himself employed the following plan with great success; in three cases out of four the recovery was permanent. Iodine and iodide of potassium were given in decoction of elm-bark, and the affected parts were dressed with an ointment containing, at first, twenty grains, and afterwards a drachm of iodide of potassium to an ounce of lard and a drachm of glycerine. Alkaline baths, containing a drachm of carbonate of soda to a gallon of water, were used a quarter of an hour before the ointment was rubbed in, and the flesh-brush was freely employed while the patient was in the bath.

In the spinous or warty form, which, as I have said under the head of definition, I mean to be understood as an aggravated variety of simple ichthyosis, Mr. Wilson advises that the skin should be softened with warm alkaline washes and baths, and then stimulated with a lotion such as that of the tincture of croton.[2] Constitutional remedies may be tried, and both Fowler's and Donovan's solutions will be found useful. He advises also a course of liquor potassæ in decoction of sarsaparilla. Willan and Elliotson have both recommended pitch, to the extent of half an ounce daily. I have had no experience of it in this rare variety, but from what I have seen of the action of pitch in other complaints, I should not expect much effect from it. In the case I speak of there were several complete ridges of long, but rather soft, spines. They were all limited to one side of the body, and were seated on the side, shoulder, upper part of the chest and neck. Many of the spines were two-fifths to half an-inch in length. This patient was a lad of thirteen or fourteen years old. The case underwent no improvement, and I soon lost sight of him.

Mr. Naylor says[3] that in ichthyosis there is generally a great excess in the quantity of urine which is, moreover, of a low specific gravity, and usually of the palest yellow colour. In a specimen which I examined lately, a portion of the whole bulk of urine passed during the twenty-four hours by a little girl six years old, labouring under this disease, the colour was decidedly pale and the specific gravity 1016. It was acid, and yielded a very small quantity of mucus. Half-an-ounce treated in the way recommended by Bird,[4] gave gr. 0·90 of nitrate of urea, and little more than traces of uric acid were found. The addition of nitric acid produced a greenish gray colour. There was no albumen, and no excess of bile. An ounce produced 1·80 gr. of extremely hard white ash. Judging as well as one can from these slight indications, it might be worth while to try the effect of colchicum and acetate of potass.

The sebaceous variety is, when the patient will give us fair play, by no means such a formidable affair. Warm baths, frictions, bichloride of mercury in emulsion of bitter almonds, with laxative medicines, are recommended by some authors.

In the chapter on eczema, I hope to be able to give my reasons for referring to this disorder, the two cases of sebaceous ichthyosis, so ably and lucidly related by Dr. Ogle in the Transactions of the Medico-Chirurgical Society, and treating them as varieties of eczema, to be met with steel and arsenic. But the complaint is so rare that few men ever have had, or will have, much experience as to the real effects of treatment upon it.

(To be continued.)

1 *Edinburgh Medical Journal*, 1861-2, p. 1.

2 Mr. Wilson's form for the tincture of croton is—

℞ Semin contus, ℥i.
Spir. vini. rectif., ℥iv.

Macera per dies quatuordecim et cola. The lotion consists of a drachm of the tincture to half a-pint of fluid.

EXTRAVASATION OF URINE, FROM BURSTING OF THE URETHRA BEHIND A STRICTURE OF LONG DURATION.

PERINEAL SECTION: RECOVERY.

By HENRY GRAY CROLY, F.R.C.S.I.,
SURGEON TO THE CITY OF DUBLIN HOSPITAL.

VISITED, in consultation with his medical attendant, Mr. ——, who had been suffering for years from stricture of the urethra, for the relief of which instruments had been introduced from time to time.

About a week before my visit he felt a swelling in the perineum, for which, however, he did not seek advice. He passed water (as usual with difficulty) until the night before I saw him, when he felt an unusual and painful sensation in the perinæum "as if something had given way," and soon afterwards he found the scrotum becoming much enlarged. This swelling increased rapidly, and he passed a restless night; being alarmed, he sent for his medical attendant in the morning, who recognised the serious nature of the case, and recommended additional advice.

On examination, I found him in the following condition:—Scrotum enormously distended, and of a shining red colour, a fluctuating tumour, the size of a hen's egg, occupying the median line of the perinæum. He said that he passed some urine with great pain and difficulty during the night, after the sensation of "something having given way." His pulse was 136 in the minute, his tongue was furred, and other symptoms of constitutional disturbance were present. The room had a strong smell of ammoniacal urine. The urgent necessity for immediate operation was explained to the patient, to which he readily consented.

Having placed him on a table in the lithotomy position, and the pelvis being raised on a pillow, I endeavoured to introduce a catheter into the bladder, but found a stricture (near the bulb), through which the instrument would not pass. I then introduced "Syme's staff" down to the stricture, and with a long straight bistoury made a deep and free incision in the median line of the perinæum, over the tumour. A large quantity of pus escaped. I next introduced the forefinger of my left hand deeply into the wound, and felt for the staff, and having reached it, I got the knife into the groove, and opened the urethra freely from behind forwards. Scarcely any blood flowed from the incision.

I then made three long and deep incisions into the scrotum, which was enormously infiltrated—a large quantity of fluid, smelling strongly of urine, escaped. The edges of the incisions bled freely; pledgets of lint steeped in oil of turpentine were applied, and a T bandage. The scrotum was kept elevated. The patient was placed in bed with a hot jar to his feet; wine was given, and a full opiate administered. On the following day I ascertained that the patient had a rigor, and vomited soon after the operation; pulse 100 in the minute. He expressed great relief; slept well; urine passing freely through the perineal wound; scrotum much reduced in size. The pledgets of lint were removed, and the incisions were washed thoroughly, and subsequently dressed with carbolic acid lotion. Half a grain of opium and a grain of quinine to

be given every hour; also brandy and eggs with strong beef-tea.

On the third day I observed a superficial redness in the left iliac region, along the track of the spermatic cord, tender on pressure, and at once made a free incision into the part. This relieved the tension, and prevented further mischief in that region.

The bowels not having been freed for several days, a turpentine enema was administered with "O'Beirne's tube." Urine continued to pass freely through the wound in the perineum, and in small quantities through the urethra. Tincture of perchloride of iron in brandy and water was given every fourth hour. The scrotum was poulticed with linseed meal and solution of carbolic acid; a catheter was passed regularly to dilate the urethra. The carbolic acid dressing proved very valuable, and tended materially to promote healthy granulation. The wounds healed rapidly and the patient made a satisfactory recovery.

From the history of the foregoing instructive case there can be no doubt that the urethra, which was dilated behind the stricture, communicated with an abscess by ulceration, causing the infiltration of urine, and the dangerous symptoms which resulted. The treatment in such cases must be decided and prompt—the incisions must be free and deep, and the urethra must be opened behind the stricture.

BURSITIS: PALLIATIVE AND RADICAL TREATMENT.

By P. C. LITTLE, F.R.C.S.I., Etc.

At present much attention is justly devoted to affections of the knee. In your ably-conducted journal (Vol. ii., No. 52), I had occasion to comment upon injuries of the knee-joint by foreign bodies, and I now beg to add some remarks upon bursitis—an inflammatory condition in the vicinity of that joint, as manifested in the following case:—

January 10th, 1868.—T. H., aged 27, an iron-moulder, of light complexion, scrofulous and delicate appearance, consulted me for a painful swelling of both knees. For a few years passed, he felt numbness over the patellæ, attributed to the pressure of an iron-bound moulding box of about three-quarters of a hundredweight, which he used to support above "the knee-caps." During the last five months, he experienced soreness of the knees, especially when kneeling in damp sand, which he was obliged to do every day in his business. Some weeks ago, a considerable tumour appeared rather suddenly upon the right patella, which soon became red, hot, and sensitive. The left knee was also slightly enlarged and tender. I advised rest of the limbs in the extended position; hot poppy fomentations to the right knee; saline purgatives; light and nutritious, but unstimulating diet; and, subsequently, bitter tonics. In a few days, the high inflammatory symptoms were thus subdued; and, by counter-irritation with sinapisms and tincture of iodine, in about four weeks the swelling entirely disappeared from the right knee, leaving the integuments condensed and adherent to the patella. The left knee was still somewhat enlarged, but the patient being otherwise well, with my consent, resumed his work on the 17th of February.

March 14th.—He again sought relief from me, as the left knee had become so large, stiff and sore, that he was no longer able to kneel at his business. The tumour was now of an oval shape, and of great size. It extended in the line of the limb for six inches—*i.e.*, from about an inch above the patella to an inch below the tubercle of the tibia. Transversely from one femoral condyle to the other, it measured five inches. The skin over it bore no signs of inflammation. It felt cool, dense, doughy, and full of fluid.

I decided upon at once tapping it, which I did in this way: I selected a prominent spot about an inch above and external to the tubercle of the tibia, on which I directed the anæsthetic spray until sensibility was suspended. With a lancet, I then divided the hypertrophied structures as far as the bursal cavity, which with much difficulty I penetrated with a trocar and canula, giving exit to about eight ounces of viscid yellow coloured fluid, mixed with serosanguineous matter, and a few small flocculent particles, like semi-coagulated albumen. I then made moderate pressure over the sack to induce irritation; and, with the same object, introduced through the canula two plies of dentist's silk. After that I withdrew the instrument, ordered the patient to rest quietly in bed, keep his bowels free, and take only light food.

On examination I found that the fluid so evacuated was alkaline, contained albumen and fibrine in large quantities, and its specific gravity was 1022.

March 16.—There was no sign of inflammation about the knee. The bursa had refilled with fluid. Again I let it out with the trocar and canula, and injected into the synovial cavity a half an ounce of tincture of iodine, in combination with an ounce of water, which I retained in the sac for nearly five minutes, while I kneaded the walls of the bursa to excite inflammation. After which I allowed the injection to trickle away, guided by the silk thread which I replaced.

18th.—Much irritation had been produced, but the sac was again fully distended. I emptied it as before, and subsequently on nine consecutive days, without much prospect of effecting a radical cure. However, on the last of those occasions (27th March), I made a final effort, by rubbing briskly together for a long time the inner surfaces of the cavity.

29th.—Two days after the latter proceeding, high inflammatory symptoms set in. The knee became very warm, angry-looking, and swollen. It was also hard and extremely sensitive. The structures of the joint were unaffected, as I ascertained by my communicating a strong impulse to under surface of os calcis, without increase of pain. There were sharp febrile manifestations, intense heat of skin, headache, flushing of face, shivering, sickness of stomach, pain of the back, constant thirst, constipation, and much nervous and mental disturbance. The pulse was full, bounding, and quick—98. I prescribed a saline aperient with Daffy's elixir to free the bowels well, hot linseed poultices to the knee, low diet, and abundance of cold drinks.

31st.—He complained of sleeplessness for the last two nights, loss of appetite, frequent rigors, physical prostration, anxiety of mind, and unaccountable fear. I was informed that he had been delirious at times since my last visit. The pulse was strong and rapid—116. The knee appeared highly inflamed, dusky, distended to the utmost, and very sensitive. I gently passed a blunt pointed probe through the old orifice, and about a half-pint of thick grumous matter gushed out. The pulse at once fell to 88, soft and tranquil; the features became composed, the bowels rumbled, and the other distressing symptoms at once subsided. I then attached the limb to a splint, extending from the back of the thigh to the heel; recommended the knee to be constantly poulticed; wine in moderation, and plenty of beef-tea, &c., to be given.

April 1st.—He was much better; pulse 84, rather weak; bowels confined; joint much swollen; duskiness over patella, at both sides of which (especially the outer) there was an extensive blush of erysipelas, with œdema and tenderness on deep pressure. I advised the saline purgative as before, the poultice to completely envelop the joint, and wine to be taken more freely.

3rd.—On my removing the poultice to-day, the cold air seemed to cause such contraction of the integuments, that a large quantity of pus with bloody serum spouted out of the little aperture, with great relief to the sufferer. The pulse was 68, quite natural. The treatment to be continued.

8th.—There was no discharge to-day, and the cavity seemed obliterated. I therefore applied evenly from the toes to above the patella a bandage, which the patient felt very agreeable. I then allowed him to get up and sup-

port his leg on a chair for a few days. His appetite being indifferent, I prescribed Tinct. ferri muriat., and for the knee cold douches morning and evening, with frictions of compound camphor liniment afterwards. By such means, in about a fortnight more, he was quite well. The integuments over the patella became indurated and adherent, causing a feeling of stiffness about the joint, which daily grew less, and he has since followed, without any inconvenience, his arduous calling. As a preventive of future injury to the knees, I recommended him to wear a piece of thick sheep-skin with the wool on, stitched on the inside of the knees of his work-trousers, which, I have no doubt, will answer the desirable end in view.

The most perfect of all mechanisms—the human frame, is endowed with protective qualities which challenge our admiration. The character of rotundity which pervades the exterior of the body, as well as its internal organism, the graceful curvatures of the long bones and spinal column, the inter-osseous and inter-articular cartilages, the prevalence of areolar, fatty, or dense tissues, where pressure is more likely to occur, bespeak a supreme prescience. On the same principle, we find in some regions, between bone and muscles, tendon and integument, an intermediate element which modifies the resistance of those opposed substances, as well as diminishes impulses from external causes. Such are the character and use of the cavities called *bursæ*, which are either natural, as that between the integument of the knee and patella, or adventitious—the product of circumstances. Much diversity of opinion exists as to the nature of these structures.

1. Some with Abernethy hold, that they are *bursæ mucosæ*, which is incorrect, as their secretion is not merely mucus, but, according to Virchow, is very similar to colloid matter.

2. Kölliker considers them to be only enlarged spaces of areolar tissue, as they are not lined throughout with epithelium. He, however, observes that the membrane is wanting, precisely where pressure is made. May not such deficiencies be the result of a morbid action, as in the case of arthritis with erosion, or absorption of synovial membrane? The constant or excessive attrition at those particular parts, may have removed the delicate lining, as a similar cause is known to change a cutaneous surface into a mucous membrane. Or, the absence of epithelium from those salient points, may be a normal provision in the economy for the percolation of the peculiar bursal secretion, for which Kölliker has failed to account. Such explanations would appear to simplify this obscure and important matter.

3. Many view those recesses only in the light of their contents, and call them, therefore, *synovial bursæ*. That would be an easy way to dispose of the yet unsolved pathological difficulties of the subject, and is no less than a *petitio principii*. Clapton Havers was of opinion, that, synovial secretion was generated in the fat-cells which exist in the joint tissues. That view vanished immediately upon chemical examination by Frerichs, who found that this fluid contained many of the constituents of blood. It would not, therefore, be unreasonable to suppose, that, the former was an exudation of the latter, resulting either from inflammatory action, or from an atonic condition of the vessels in the areolar tissue, or synovial membrane. That the inner lining of enlarged bursæ resembles, if it be not really the same as that of the neighbouring joint, appears probable from established facts. The synovial membrane of the knee-joint is sometimes known to embrace the tubercle of the tibia, which explains the occasional development of synovitis in the progress of bursitis, especially after puncturing the bursa. In the case before me, I hesitated taking that step lest such a consequence might ensue. Again, bursitis (as in this case) is often attended with most of the local, and all the constitutional, symptoms of inflammation of the synovial membrane of the joint.

There is little to remark touching my treatment, which was palliative as regards the right knee, and radical as to the left. I was much surprised that the latter was so slow in taking on inflammatory action, especially after the iodine injection. The manipulative process, which was so successful in setting up that condition, has many advantages, amongst which are its simplicity, readiness, safety, and certainty. I believe this plan may, with propriety, be resorted to in all chronic tumours which require irritation, or the greatest vascular excitement, for their cure. I have heard that Mr. Syme applies it largely and heroically in hydrocele of the tunica vaginals, after evacuation of the fluid, and with entire satisfaction. It may be observed that, after kneading the bursa, I did not for some days again let out its contents, although much general distress was thereby caused. My reason for abstaining was, to allow of adhesive inflammation to fairly set in around the circumference of the cavity. On the same grounds, I think it unwise to evacuate the pus as soon as secreted. The process of union would be thus retarded, and a weak state of the vessels induced. The general nervous disturbance and delirium were here remarkable, and reminded me of similar conditions I have observed during the radical cure of hydrocele. We may find the explanation of those serious symptoms in the high nervous organization with which the knee, like the testis, is endowed. The knee-joint was the only articulation into whose tissues Kölliker could trace nerve filaments.

I found, in the after-management of the case, a powerful agent in a back splint which steadied the joint, and so promoted the amalgamation of the walls of the bursa. The subsequent steps which completed the recovery of the patient need no notice, as they were such as are generally adopted.

I fear I have availed too largely of your valuable space. I shall therefore conclude with the hope, that at a future time I may return to the subject of knee affections in connection with acute and chronic rheumatism.

Hospital Report.

GUY'S HOSPITAL.

CASES ILLUSTRATING THE SPONTANEOUS CURE AND DEGENERATION OF NÆVI.

Under the care of THOMAS BRYANT, F.R.C.S.

THE following cases of spontaneous degeneration and inflammation of nævi will probably be read with interest; for they well illustrate the fact that there is a tendency in all nævoid growths to undergo a natural cure, and tend to suggest that operative interference is not required in all such cases.

I publish them simply as illustrative of the above remarks, it being foreign to my purpose to enter upon the treatment of this affection; but this, I may say, that unless a nævus is so situated as to be an eye-sore, or an inconvenience, and unless it shows positive evidence of its tendency to rapid increase, there is no necessity for operative interference; it will, to a certainty, after a time cease to grow, and will also to a certainty begin to degenerate or waste, and under these circumstances in a large proportion of cases it is hardly necessary to interfere. Under other conditions, however, active treatment is demanded.

The cases which I now publish illustrate these points. Cases 1 and 2 show how nævi may begin to ulcerate and degenerate during the uterine existence of the fœtus. Cases 3, 4, and 5, how the same curative process may appear soon after its birth. Cases 6 and 7 are admirable illustrations of the very peculiar warty and cystic degeneration which nævi naturally undergo. The warts in these cases are soft and spongy in character, easily bleeding when touched; they are specially characteristic of the degenerating nævus, and when once seen can hardly be mistaken for anything else.

Cases 8 and 9 show how those nævi may also inflame and suppurate, and even in rare cases slough out as a whole.

But, it is to be observed, that all these actions are spontaneous; they take place without any local treatment; they are the direct result of natural processes, and tend towards the natural cure of the disease.

NÆVUS ULCERATING AT BIRTH.

Case 1.—Amy H., five weeks old, was brought to me at Guy's Hospital, on December 15th, 1862, with a nævus involving half the nose. It had existed from birth, and was also ulcerating. The mother told me that it was sore and discharging when the child was first born. It had not grown.

As a case of nævus which had commenced to ulcerate and degenerate before the birth of the child, the case was a good one.

NÆVUS DEGENERATING AT BIRTH AS A WARTY AND CYSTIC DISEASE.

Case 2.—Arthur K., eight months old, was brought to me at Guy's Hospital, on March 10th, 1864, having been sent up from Gravesend by Dr. Armstrong. He was the subject of a large nævus involving the left half of the skin and cellular tissue covering the abdomen. This nævus was clearly undergoing degeneration, for it was the seat of a warty cystic growth, such as exists in such an affection. These cysts and warts were said to have been present at the child's birth, but to have become more numerous since. The child was under observation for some time, and the nævus clearly went on degenerating as usual in such a complaint.

DEGENERATING AND ULCERATING NÆVUS—CURED.

Case 3.—Edward James, æt. seven months, came under my care at Guy's Hospital, on July 31st, 1865, with a nævus the size of a shilling over the right scapula. It had existed from birth, but had increased in size, and for several weeks had become sore and discharged. When seen the nævus was clearly undergoing degeneration, for it was ulcerated over the whole of its surface. This ulceration continued, and when it had cicatrized the nævus was cured.

NÆVUS DEGENERATING AND ULCERATING SOON AFTER BIRTH.

Case 4.—Dora A., æt. six weeks, came under my care at Guy's Hospital, on March 13th, 1867, for a large nævus over the right buttock. It was much ulcerated, and had been so from the second day of the child's birth. This ulceration continued till the growth was nearly cured, and when it had cicatrized the nævoid structure appeared to be destroyed.

NÆVUS ULCERATING AND DEGENERATING SOON AFTER BIRTH.

Case 5.—Hannah F., æt. seven months, came under my care at Guy's Hospital, on March 14th, 1861, for a nævus of the mixed kind, involving the lower part of the right ear and parts below. It had grown gradually from birth, but for one month had been ulcerated over a great part of its surface; it was clearly degenerating.

NÆVUS UNDERGOING WARTY DEGENERATION.

Case 6.—Margaret S., æt. 10, came under my care at Guy's Hospital, in Nov. 10, 1861. She had been born with a nævus, the size of a crown, on the anterior part of her thigh, which increased with her growth for some years; for the last two years it had, however, ceased to enlarge, but upon its surface currant like bodies had appeared, which often burst and bled.

When coming under my care the whole growth was the subject of a cystic degeneration; its surface was studded with vesicular warts, some indurated, others translucent, discharging a blood-stained serum on being punctured.

It formed a very beautiful example of a degenerating nævus. Excision was advised but rejected.

NÆVUS IN CHEEK UNDERGOING CYSTIC DEGENERATION.

Case 7.—Ellen Hoil, æt. 24, came under my care at Guy's Hospital, on January 24, 1867. She had been under my observation four years previously for the same disease—a nævus, involving the whole thickness of her left cheek. This nævus had clearly been gradually undergoing degenerative changes, for the mucous lining of the cheek was the seat of a peculiar cystic warty growth, such as alone exists in a degenerating nævus. The nævus, during the four years, had not increased in size, but, on the contrary, had become more localized.

No surgical treatment was called for, as the growth was gradually becoming cured by natural processes.

NÆVUS ON HEAD, SUPPURATION AND RECOVERY.

Case 8.—Bertha M., 13 months of age, was brought to me at Guy's Hospital, on Nov. 10, 1862, for a nævus over the vertix of the skull, which had been growing till about six or seven weeks since, when it suddenly inflamed. When coming under observation the whole growth was indurated and discharging from several openings. Suppuration continued for three weeks, when the orifices closed, and the nævus underwent a rapid recovery.

NÆVUS ON THE BACK WHICH SLOUGHED OUT.

Case 9.—Eliza H., aged 6 months, came under my care at Guy's Hospital, in August 22, 1867, for a nævus which was clearly sloughing out as a whole. It had existed at birth, and had grown for some weeks, when it became sore and ulcerated. It then inflamed, and when I saw the child the nævus was evidently sloughing out as a whole. The slough separated readily by itself, and left a clean granulating surface as in a cellular membranous ulcer; when this had cicatrized, a good cure had taken place.

This case is the only one in which I have seen a nævus slough out as a whole.

Literature.

VISCERAL SYPHILIS.

"IN DUBIO, SUSPICE VENEREM."

CERTAINLY syphilis is a most important and protean disease, if we may judge from the numbers of works which yearly issue from the press, to illustrate some points in its history. The little work before us[1] is a most admirable and learned synopsis of all that has been written of late years upon the diseases of the viscera, said to be due to syphilis, and should be read by all who desire to learn how the question stands at this moment. Our author quotes from a vast number of writers, among whom we may mention Ricord, Rayer, Vidal, Gubler, Cullerier, Baerensprung, Simpson, Hutchinson, Virchow, Diday, Gibb, Jackson, Parker, Türk, Wilks, Moxon, and many others, to show that syphilis may affect every viscus, and even the muscles and the heart. He inclines to Virchow's theory of cellular hyperplasia, as accounting for the lesions found in the organs, and shows that these lesions occur in two different forms, the circumscribed and diffused, the former of which has been known by the name of *gummy tumour*. The period in which these inflammations attack the viscera is usually the tertiary stage, four, ten, or more years of the infection, and death sometimes is caused by cachexia. As to the nervous diseases referrible to syphilis, there is, first, syphilitic meningitis, which usually attacks the dura mater, causing giddiness, pain in one spot, or epileptic fits, these latter being one of the forms of that disease most amenable to treatment by large doses, such as gr. x.—gr. xv. of pot. iod., *t. d.* The os frontis and petrous bones are those most frequently attacked with caries. Our author does not speak of the dry caries, so well described by Wilks and others. Gummy tumours are sometimes observed in the brain (Lancereaux). Yellow spots are found in the cerebrum and cerebellum, causing impairment of the intellect, convulsions, and paralysis of certain muscles. Iodide of potassium, again, is valuable in such cases, in large doses. Hydrocephalus, our author thinks, is sometimes ascribable to hereditary syphilis, and Hutchinson is quoted, as referring idiocy in children to it. Dementia in adults may occur from softened gummata in the brain. The nerves affected in syphilis are principally the levator palpibrae superoris, and the

1 Visceral and Hereditary Syphilis. By F. Oppert, M.D. London: Churchill. Pp. 100.

branches of the fifth nerve. Retinitis and choroiditis syphilitica are now generally recognised, and the ophthalmoscope has pointed out various lesions of the internal eye, causing amaurosis. Interstitial keratitis, both in inherited and acquired syphilis, is by no means unfrequent. Deafness is common in cases of inherited syphilis, not in adult cases. Ozæna may cause anosmia, and gummata may cause loss of taste. Dr. M'Dowell relates cases of gummy tumours in the spinal cord, with palsy of the lower limbs; and Yvaren, Lancereaux, &c., speak of syphilitic sciatica, neuralgia, &c., cured by large doses of pot. iod.

Among the most important of the lesions caused by syphilis, are those of the larynx and trachea, especially in the tertiary stage; considerable loss of substance in the larynx may occur, and portions of the organ may be necrosed. Œdema of the glottis occasionally, though rarely, occurs. The cachexia in such cases is great. Solutions of tannin and atomized fluids inhaled, often do much good in such cases. Ulcers occur low down in the trachea. Abscesses of the thymus gland occur in infantile syphilis. Syphilis apparently causes inflammation and ulceration of the bronchiæ. Erythema of the mucous membrane is the commonest form of the disease. Gummata in the lungs not unfrequently simulate tubercular phthisis, and cases of the kind are cited by Virchow and Ricord. Wilks and Haldane have alleged that syphilis affects the heart, and gummata have been seen in its substance; but the liver is the internal organ of the body (Gubler) most frequently attacked by syphilitic deposits, especially in syphilitic infants there is interstitial hepatitis, and gummata are also seen enclosed in a capsule, or there may be amyloid degeneration of the organ (Frerichs). The spleen is sometimes affected with fibrous, fatty, or cheesy deposits (Beer); or sulphur-yellow deposits (Moxon). Gummata are often seen in the tongue, and the pharynx and œsophagus may contain such growths. Moxon and Wilks speak of lardaceous syphilitic disease of the colon, and stricture of the rectum. Rayer, in 1840, referred certain renal degenerations to syphilitic cachexia; and Moxon seems to consider amyloid degeneration as caused by it. Such kidneys are much enlarged, and there is fatty degeneration of the cortical portion, with yellow spots interspersed through it (Beer). Gummata have also been found. Albuminuria frequently exists in such cases.

It would appear, according to Lancereaux, that syphilis causes frequently ovarian affections; gummata are found, and these, it seems, may produce sterility. Hypertrophy of the womb is also said to be caused by it, and the placenta becomes degenerated and atrophied, causing abortion (Barnes). The testis is frequently affected with gummata, a growth very like tubercle of the testis. Iodide of potassium, gr. xx. *t. d.*, is very effective in this disease, if administered in time. It appears then that in many cases of inveterate syphilis, we may suspect that the internal organs are affected, and accordingly prescribe iodide of potassium. Our author is opposed to the ideas put forward by Jenner, F. Jordan, &c., as to scrofula being frequently a transformation of syphilis, and appears to agree with Hutchinson, Drysdale, &c., on this head. He would allow patients to marry a year after all symptoms of syphilis have disappeared. "Of course," he adds, "sexual intercourse may be interdicted (if persons are already married), or carried on under certain restrictions." Hereditary syphilis may, according to our author, arise from either parent. Cullerier and Simonet think that the mother *must* be infected first. He treats syphilitic children with mercury and chalk, and iodide of potassium, and, altogether, speaks well of mercury, though he seems more a believer in the last named drug.

With regard to prevention, he thinks that only certain classes of males can be subjected to examination, and mentions, with disapprobation, the Hamburgh plan of examining all men who frequent brothels. He appears in favour of a law for the examination of prostitutes, but without using severity. Special wards should be formed for them in large hospitals, and they should be treated with humanity and care. The younger members of the profession should be advised to study the whole question of syphilis most diligently, since the frequency of visceral syphilis is far greater than is believed. Syphilis is an international plague, but its spread may be prevented, if we cannot stamp it out, by legislation. In short, the remarks made by our author are full of interest, and we heartily recommend his work to the attention of our readers.

THE death of M. Stein, a well-known member of the Danish medical profession, is announced.

GERMAN MEDICAL LITERATURE.[1]

Professor Baerensprung is known as one of the first continental authorities on skin diseases to all who are acquainted with the literature of that subject. He had just begun a large work which was intended to be a standard work on German dermatology; but when the first part was published, the author met with an untimely death. The publisher therefore placed Professor Baerensprung's manuscripts and drawings into the experienced hands of Hebra, who readily promised his co-operation in publishing the Atlas and text—the first part of which is before us. It would be superfluous to say a word of the mode in which the work is brought out. Dr. Heitzmann is known to us as a skilful draftsman from Hebra's large atlas, and for the part which has been done by Hebra himself, the name is sufficient guarantee for the texts being written scientifically, clearly, and, at the same time, pleasantly and concisely, according to Hebra's mode of writing.

The first part contains, besides the text, ten plates, representing—1. Erythema, exudativum multiforme; 2. Urticaria; 3. Herpes facialis; 4. Herpes progenialis; 5. Herpes iris; 6. Herpes zoster; 7. Herpes circinatus.

The specimens chosen for the drawings fairly represent the special affections, so that by their aid, it would not be the slightest difficulty to recognise the disease in question. We therefore recommend the atlas to every practitioner who wishes to make himself familiar with the various diseases of the skin, the study of which is impossible without either living specimens or good representations of their cutaneous alterations.

A new part has just been published of that work,[2] which is intended to form a repository for the experiments, researches, and experience of the best of the German authors, all being well-known teachers in the different German medical schools. Seven parts have been published till now, one of them forming an excellent atlas of surgical operations, instruments, and topographical anatomy. In these parts, one name is particularly conspicuous, not only from the lion's share its bearer took in the work, but from the intrinsic value of his various papers—we mean Otto Weber, the late Professor of Surgery at the University of Heidelberg, whose obituary found no less an author than John Simon, President of the Pathological Society of London.

The work will not only be read by surgeons, but by physicians also, who are equally interested in general and special pathology of morbid growth and other affections, in the microscopic appearances of deteriorated tissues, in the mode how topographical anatomy has been treated in the different parts of the work, and in other objects of equal importance.

It would, of course, require much more space than we can command, to give even the mere outlines of the subjects contained in the parts before us. We must, therefore, content ourselves in saying, that many things have been introduced in a manner which reflect the highest credit on their authors. To name only one amongst many, we refer the reader to the second part of the first volume, which contains a treatise of Dr. Fisher, Staff-Surgeon in the Prussian Army, on military surgery, as studied on the battle-field.

This treatise, which would form a pretty volume by itself, not only enters into the question of how the different field pieces and arms act, how the wounded soldiers are to be treated on the battle-field and after the battle, but likewise gives full descriptions of so-called flying hospitals, and of all the arrangements which have been applied with benefit during the last war.

Professor Billroth's paper on poisoned wounds, and Dr. Nussbaums' essay on anæsthetics, general and local, are neither of less importance, nor less interestingly written. The first part of the third volume contains Dr. Trœltsch's paper, which is an abstract of the whole modern oral surgery, and the last published part (first of the second volume,) is the beginning of Professor Luecke's work on pathology and treatment of

morbid growth, which exhausts the subject in a remarkable manner. All these papers are fully illustrated, and the microscopical appearances very minutely represented.

We have just only touched on a few subjects, which in many works of surgery are either neglected or even not mentioned at all. The parts contributed by the late Professor Otto Weber, are throughout classical, and many other essays are perfectly worthy of their place in such a prominent work as that which we have considered our duty to bring before the notice of our readers.

PROFESSIONAL EDUCATION.

IN prospect of the speedy meeting of the General Medical Council, this subject is again calling forth the opinions of many.

We have persistently, during the last few months, alluded to it, seizing every opportunity of noticing the various *brochures* that have been put forth, as well as the utterances of public speakers. It is not long since we discussed Mr. RIVINGTON'S pamphlet. Only last week we commented on Mr. BRUCE'S speech. Mr. SIMON'S views have been very fully illustrated in our columns.

We, at least, then have done our best to discharge this important duty of the medical press—full discussion of medical education.

We now invite our readers to consider a scheme of education put forth in a pamphlet by Professor PARKES.[1] This is a name that will command respect. As a teacher of many years' standing, formerly in London, now at Netley; as an examiner in medicine, and as a member of the Medical Council—Professor PARKES approaches the subject as one which must have engaged much of his attention, and upon which he speaks, as it were, with authority. His conclusions will be sure to have much weight, and certainly deserve the most candid criticism.

He lays down a plan of study extending over four years, by following which he believes a young man entering the Profession at 17 or 18 years of age, profoundly ignorant of all he desires to know, may become a safe practitioner, and as such receive his diploma; and he would make this plan compulsory on all. Now, here are two very distinct issues: first of all, the settlement of an uniform plan; secondly, the policy of making that scheme compulsory.

As to the first portion of his scheme, after giving it the fullest consideration, we are free to acknowledge that for a young man under the circumstances named we know of no better course for attaining his object. Further, we believe that any fairly diligent student who followed such a programme would have a medical education superior to that of the majority of existing practitioners.

Professor PARKES would have the whole of the four years passed at a recognized school. The first two years he would have entirely devoted to the subjects which form the foundations of medical knowledge proper—Anatomy, Physiology, Chemistry, Materia Medica, Pharmacy, Botany. All these subjects he would have taught practically—and to facilitate uniformity in the teaching, he suggests the issue of authorized text-books. The last two years would be occupied in building strictly professional knowledge on the foundations thus laid. Medicine, Surgery, Midwifery, Therapeutics, and State Medicine, are the subjects laid down. Professor PARKES would draw a very distinct line between the third and fourth years. The third he would occupy with medicine and surgery, by short courses of lectures of a practical kind, and clinical work in the wards. The fourth year would be occupied by midwifery and the other subjects named, and to the fourth year he would defer the attendance in the out-patients room, when he believes it would be of much more use.

Besides all this, Prof. PARKES would introduce school-tests of progress and other checks, both on teachers and pupils, which would, no doubt, contribute greatly to efficiency.

The whole scheme is very carefully considered in all its details, and the pamphlet ought to be studied by all interested in this great subject. We have acknowledged that such an education would be of the greatest value, and may further confess that, personally, could it have been found carried out by such men as Prof. PARKES in our day, we should have esteemed it a high privilege to follow it.

But the policy of compulsion demands a few words from us. It is urged by Prof. PARKES, that with our present system of competing licensing bodies, it is impossible to trust to the examinations as sufficient tests, and although he hopes that the corporations will render their tests more reliable than at present, he has evidently little faith that they will ever absolutely suffice, and, therefore, he has no wish to abolish the regulations which at present vex and perplex the student.

Having so freely admitted the excellence of the scheme for those who are commencing without any knowledge whatever of the subjects to be learned, we may with greater confidence urge the claims of those who are not in this condition.

It is no uncommon thing for a pupil to enter a school with a fair knowledge of some of the subjects, acquired at home or with some practitioner, or otherwise. Upon these the compulsory system would act unfairly. We have known pupils, for instance, who had gone through the courses of botany, materia medica, and chemistry at the Pharmaceutical Society, afterwards enter the Profession. Where is the justice of compelling such men to pass as many hours in going over what they know so well, and *paying* the teacher for telling them what they could as easily tell him? It is true these men are but a small minority; still compulsion admits no exceptions, and the scheme we have described is too inelastic to be applied to such cases.

This is not the only difficulty of any attempt to enforce uniformity of education—an attempt we think likely to fail, because it goes against all the prejudices of British subjects.

What is really wanted is uniformity of examination, and

1 "A Scheme of Medical Tuition." By E. A. Parkes, M.D., F.R.S., &c. London: J. Churchill and Sons.

the objection that the licensing bodies are not to be trusted admits of but one reply. They should either be compelled to do their duty or be superseded.

It is not to be expected that all will accept this conclusion, and we readily admit that there are difficulties to be encountered in the plan of complete freedom of education that many support, and that Mr. SIMON has once more brought into prominent notice. Still, these difficulties seem to us less than those to be met by the advocates of uniformity of education. There can be no difficulty in improving the standard of examination. We think it possible so to sift a man as to make the test prove all that it should—whether the candidate is fit to be allowed to practice.

When the Medical Council does its duty that will be guaranteed; but how, when, and where the candidate obtained his knowledge must ever be a matter of interest to himself and his personal friends alone.

TESTIMONIAL TO DR. RICHARDSON.

LAST Wednesday afternoon, the testimonial to Dr. Richardson was publicly presented to him at Willis's-rooms. Mr. Paget occupied the chair on the occasion, and in a neat speech, justified the presentation that had been determined upon, and so favourably responded to. He adopted, as he himself termed it, the line of a "counsel for the defence," acknowledging expressly his feeling, that "all testimonials need apologies." The introduction of this sentiment was, no doubt, intended to give force to the present exception, though the general feeling of the meeting seemed so heartily in favour of the gift on this occasion, that the apology might well have been dispensed with.

Nevertheless, we welcome it; since it shows that there is much sincerity in the general objection to testimonials, that has of late years been expressed, and the unanimity with which such feelings have been over-ridden on this occasion must, we think, prove an additional gratification to the receiver of the exceptional compliment. The number of the subscribers (about 600), and the amount (stated by the Committee at £1108, 15s. 7d.) sufficiently attest the manner in which the proposal to raise this testimonial has been received, and account for the interest excited by the presentation. One of the circumstances mentioned by Dr. Richardson in returning thanks, is also well worthy of our attention. We allude to the fact that the list of subscribers included the names of some, with whom, in his pursuits he had been brought into collison; showing that the contests were all passed by, and that the warmest opponent may be the closest friend. We know well enough, how easily such collisions occur in the course of a scientific or professional career, and it speaks well for both parties when so pleasing a termination can be so pleasantly announced. Well would it be for science and her voteries—well for medicine—well for the medical profession, could all controversy end like this. There is no need for reticence in the search for truth—Dr. Richardson is himself a proof of this; there is no necessity for emulation to degenerate into rivalry; no reason why one worker should feel jealous at the success of his brother worker. If our profession would but learn this truth, the proceedings on Wednesday last would have a still more brilliant result, and none would more rejoice in such a lesson than they who apologized for it, and he whose labours occasioned it.

The other features of the meeting were necessarily to a great extent formal, and do not suggest any remark for a leading article. We need not, however, hesitate to thank Sir Thomas Watson for the graceful manner in which he moved a formal resolution—that of thanks to the chairman. It afforded us sincere gratification to hear the pleasant, clear, ringing tones of the eloquent baronet—the *quondam* lecturer, who has done so much to diffuse literary grace over scientific teaching. Many of our country readers will rejoice to hear that apparently, without exertion, Sir Thomas filled the room with his voice so exactly, that every syllable he said could be distinctly heard in the farthest corner—a feat which no other speaker on the occasion accomplished.

Notes on Current Topics.

The Public Health.

FROM the Registrar-General's return of births and deaths in London and thirteen other large towns of the United Kingdom, we select the following figures:—In the week ending Saturday, May 16th, there were registered in those towns 4736 births and 2864 deaths. The annual rate of mortality was 23 per 1000 persons living.

The annual rate of mortality last week was 21 per 1000 in London, 25 in Edinburgh, and 27 in Dublin; 22 in Bristol, 20 in Birmingham, 26 in Liverpool, 27 in Manchester, 25 in Salford, 29 in Sheffield, 24 in Bradford, 20 in Leeds, 20 in Hull, 21 in Newcastle-upon-Tyne, and 31 in Glasgow.

In London, the births of 2223 children were registered in the week, and the deaths of 1268 persons, which are less by 63 than the estimated number.

The deaths from zymotic diseases were 273, the corrected average number being 312. Ten deaths from small-pox, 56 from measles, 31 from scarlatina, 9 from diphtheria, 58 from whooping-cough, 38 from fever, 12 from diarrhœa, and 4 from choleraic diarrhœa were registered.

One hundred and ninety-nine deaths occurred from phthisis, 101 from bronchitis, 63 from pneumonia, 59 from diseases of the heart, and 148 from diseases of the brain and nervous system.

Three persons died from *delirium tremens*, 8 infants and 2 adults from syphilis, 3 from burns or scalds, 5 from drowning, 5 infants and 1 adult from suffocation, 8 committed suicide, and 3 were killed in the streets by horses or carriages.

Royal College of Surgeons of England.

AT the coming election of three Councillors, it is stated that Mr. Hodgson will not offer himself for re-election, but that both Mr. Partridge and Sir Wm. Fergusson will again seek the suffrage of the Fellows.

We think it highly probable that both will be re-elected. There will then be one vacancy to be filled up with new blood. The senior candidate is Mr. Erasmus Wilson, who has lately proposed a Fellows' Association, and whose high scientific attainments have won him a European reputation. There are, however, several other candidates, the most formidable being, perhaps, Mr. Simon, whose extreme liberal views on education have lately been so much commented upon, and may secure him the support of advanced reformers.

We also hear that Mr. Luther Holden will again be put forward on behalf of the Fellows by examination, and we have no doubt so favourite a teacher will poll many votes. The other candidates are Mr. Gay, Mr. Cooper, and Mr. Brooke.

New Hospital at Leeds.

THE Prince of Wales at Leeds has been the topic of the

week, and, therefore, our readers may expect a few lines about the new Infirmary which he opened as an exhibition.

The Leeds General Infirmary has existed for a century, but in spite of enlargement became too small. At length it was resolved to have a new building, and the one mentioned has been built at a cost of £120,000, from the designs of Mr. Gilbert Scott.

We are glad that the pavilion principle has been adopted, and from the accounts that have been published, the new Infirmary seems not only to be an ornament to the town, but to be constructed throughout with all modern improvements to fit it for the use to which it is destined. Each ward is about 130 ft. long, 30 ft. wide, 19 ft. high. The cubic space for each patient is to be 2500 ft., as only thirty beds are to be in the wards.

Great care has been taken to ensure abundant natural ventilation. The walls of the wards are of tinted cement, and their decoration has been left to Professor Lewis.

Alfred Hospital.

One of the most singular, and yet most useful directions ever given to a sudden outburst of loyalty, is that reported as one phase of the indignation, grief, and sympathy, produced by the dastardly attempt on the life of the Duke of Edinburgh.

To those who found no vent for their feelings, it was proposed to erect a "Memorial Alfred Hospital," as a token of gratitude that the Prince had escaped with his life. Upwards of £30,000 was raised "almost instantaneously," and, we presume, that the colony will shortly possess a new hospital. Such a building will be a lasting "memorial" of the sad event, as well as a new bond between the mother country and her colonies. Would that loyalty could more often be expressed in a form so certain to benefit the suffering portion of a community.

Hospital Reform.

Mr. Sampson Gamgee has published as a sixpenny pamphlet, a revised report of his speech on this subject, at the recent Birmingham Meeting of the Medico-Political Association. In reporting that meeting we gave so full an abstract of this important speech, that our readers are fully conversant with Mr. Gamgee's views. In Mr. Gamgee the association has an able and influential supporter, and we cannot help congratulating the general practitioners of the Midland Counties upon the firm stand they have taken, and the part they have played in making an association which seeks only the elevation of the profession, so completely successful.

Plymouth Workhouse.

Dr. Stallard has published in the *Western Morning News*, an account of a visit to this workhouse. He found 180 patients under one paid nurse; a number of beds without sheets; pauper patients bed-ridden, but without water-closet or night commode; together with other faults and negligences such as have so long disgraced our pauper infirmaries. We should hope that Dr. Stallard's visit may lead to immediate change.

Army Marriages.

A pamphlet has been issued on this subject by a writer who, under the signature "Brown Bess," gives much information on marriage in the armies of Europe. He thinks it practicable to encourage marriage and prevent vice in the British Army, without any great burden being thrown upon the tax-payer, and suggests that permission to marry should be given on condition of the soldier devoting his whole life to the nation in consideration of a provision for his wife and family. Combined with this plan he would stop the pay of men incapacitated by self-induced disease.

The pamphlet contains statistics that will also be acceptable to those interested in this subject.

Edinburgh Royal Infirmary.

Mrs. Buchanan, of Moray-place, who a little while ago gave £1000 towards the rebuilding of the Medical Hospital, has supplemented that donation by another of four times the amount. It has been resolved to dedicate a ward in the new hospital to the memory of Mrs. Buchanan's late husband. The managers could scarcely do less than acknowledge in some such way this munificent gift of £5000.

Scotch Returns of the Registrar-General.

During the month of April, in the eight principal towns of Scotland, the births of 3506 children were registered. The illegitimate amounted to 8·2 per cent. The marriages were 513, being 18 under the average for the same month during the last ten years, while the deaths of 2248 persons were registered in the same eight towns. This number is 124 under the average of the month in the last ten years.

Brougham.

Many are the aspects in which we might look at this remarkable man, who gained his own standing, and brought himself into the list of those whose names stand out in greatest prominence among the men of their own times, and may, perhaps, be remembered in the latest periods of the world's history. No one, however, is more remarkable than that in which he displayed the power of his oratory. Those who have not heard him can have but a faint idea of the effect he at times produced. There were many who excelled him in the graces and amenities of speech, but few, if any, who surpassed him in power. The occasions on which it was put forth were numerous, and have been most of them referred to in one or other of the obituaries which have appeared in the various publications of the day; but there is one to which as yet we have seen no allusion made, and which we ourselves had the opportunity of witnessing. It was in the House of Commons, some years after the noted trial of Queen Caroline, when his reputation had been undeniably established. The debate was on the repeal of the Corporation and Test Acts. It was introduced by the present Earl Russell in an able though not particularly remarkable speech. Peel was the ministerial leader, who exerted all his influence against the measure, and seemed for the time, by his soft and winning eloquence, to carry the House with him. While he was speaking Brougham sat on the other side of the table, apparently not over attentive. He was seen at one time writing a note, and sending to a member behind him; at another, conversing in a whisper with some one near him; and then taking a book from the table and reading it in the most argumentative portion of the Minister's speech. But all the while he was undoubtedly preparing himself for the strife. For, the moment Peel ceased speaking, he was on his feet; though another member caught the eye of the Speaker, and he was obliged to bide his time. At length his turn came, and as

he proceeded we were struck more and more with the force of his withering sarcasm, and the manner in which he held up his opponent to ridicule, amid the ringing and irrepressible laughter of the whole assembly. At that moment Peel rose and left the House, when the peals were simultaneously renewed. He then seriously enforced his arguments for the measure, and in the most earnest and solemn tones spoke of the awful profanation of which we were guilty in making the holiest rite of our religion a stepping-stone to office—not the meanest exciseman, not even the King's rabbit-warren keeper being received into place without having first received the sacrament, however profane he might be. This part of his address produced an almost breathless, death-like silence, and if he had but paused for a moment, we verily believe a pin would have been heard, had it at the instant been let fall on the table of the house. Never shall we forget the splendid contrast produced—the opposite emotions excited in minds not over susceptible, and in a comparatively insignificant space of time, by the great master-spirit of the scene.

Excision of the Clavicle.

The *Cincinnati Lancet and Observer* of January records a case in which Dr. W. W. Dawson, of the Commercial Hospital, excised the entire right clavicle for necrosis. He also removed a small point of caries from the outer surface of the first rib. Forty-six days after the operation the wound was completely healed.

The Contagious Diseases Act.

The inquiry of Lord Lifford, from the Government, as to the extension of the benefits of this Act to the civil population is of much interest to the profession, as it elicited a declaration entirely favourable to the principle of the measure, and an expression of confidence on the part of the authorities, in the results of our late experience of the working of the Act. No objection was urged by the Duke of Marlborough to the universal adoption of the Act, on the ground either of the inapplicability of the machinery to a more extended supervision, or on the ground of the interference with the liberty of the subject, of which we have heard so much.

The results of the working of the Act, as a protection to the army and navy are so explicit and definite, as to thoroughly convince practical men that the end has completely justified the means—that supervision of prostitution is not only feasible in practice, but defensible in principle.

We cannot take exception to the reason urged by the Duke of Marlborough to its extension to the civil population. The serious expense is an objection, which under present circumstances may be justly pleaded. It is, however, a difficulty which, now that the principle is accepted and the machinery provided, may and *must* be got over, and we cannot believe that the protection of the public health against the ravages of a pestilence far more noisome and enduring than small-pox can be indefinitely postponed on the ground of an expenditure, which is well incurred for so great a result.

The Coroner's Court in Ireland.

Undoubtedly the most essential steps towards the detection of crime, and the vindication of the law against riminals, are those which are initiated immediately upon the perpetration of the offence, and no retribution is so telling or so certainly just, as that which puts the apprehension of the actual culprit and the detection of his guilt, in the relation of cause and effect. A prolonged delay in the punishment of the criminal always tends to his ultimate escape, and is in itself, in some measure, an actual miscarriage of justice, and the signal failure of the prosecutions of the Clerkenwell assassins has taught us that the process of law which is "short, sharp, and decisive" is, so long as it is exercised with impassionate dignity, that which is most effectual. This much-to-be-desired attribute of unerring and immediate retribution has been, in the late Irish State trials, almost wholly overridden by the cumbersome paraphernalia of the law, as administered by those who were personally interested in the interposition of delays and obstructions. We have had a surfeit of legal arguments, writs of error, and all those ingredients of which a good bill of costs is made up, and, for result, we have had a languid and stumbling pursuit of the criminals, and after all a very partial success in their detection and punishment. In brief phrase, we have had too much law and too little justice.

We have digressed in this direction, to give point to the many imperfections of the Coroner's system in Ireland. Dr. Mapother, in a recent communication to the Dublin Statistical Society, exposed the total inefficiency of the Irish inquest system, and his animadversions have been effectively supplemented by a sensible editorial article in *Saunder's News Letter* of the 13th.

No investigation can be so complete and exhaustive, if it be properly conducted, as that which follows immediately on the occurrence which is its subject, and yet, we do not hesitate to say, that we believe the Irish inquest system to be more efficacious towards the concealment of crime than its elucidation. With a jury incapable either in mental capacity or education—as nine out of ten Irish Coroner's juries are—of forming any reliable opinion, the *role* of judge and jury is necessarily thrown upon the Coroner, and it is not detracting either from the capacity or the integrity of that official to say, that he is usually unfitted for so great a trust. A tribunal composed of idle boys, tramps, and labourers out of work, takes the safest course in echoing, submissively, what is put into their mouth by the Coroner and the police, and in the great majority of inquests, fortunately this way out of the difficulty is adopted, but we have not sufficient trust in the energy and sharp-sightedness of the Coroner, or the absence of prejudice in the police, to leave the initial investigation of crime to them. If no more reliable judges of the causes of violent death can be provided, the sooner the entire system is abrogated and the whole onus of investigation thrown upon the police, untrammelled by a nominal and totally unreliable investigation which may probably have failed to discover any suspicious element in the case.

Climate of Natal.

The Government of this colony has requested reports on its climate, from a number of resident medical men. The entire medical staff of the colony has reported on the subject, and with considerable unanimity. They recommend the climate as particularly suitable for persons of a strumous disposition, which temperament is, we are assured by some, very rare among the natives. As to advanced consumption there seems some difference of opinion. Some have seen cavitiesheal ; others have observed them speedily prove

fatal—an experience common to most climates. In the early stages of phthisis all speak well of the climate of Natal.

The King's Professorship of Medicine in the University of Dublin.

THE election to the Chair of Medicine, vacant by the resignation of Professor Banks as recorded in THE MEDICAL PRESS AND CIRCULAR some months ago, is fixed for the 24th of July, and has excited much interest in the profession in Dublin. The candidates who now contest the occupancy of the chair are, Dr. Henry Kennedy, Dr. William Moore, and Mr. Foot, and the respective claims of these gentlemen are very actively canvassed in medical circles. Dr. Kennedy is a Bachelor of Medicine of 20 years' standing, Physician to the only Fever Hospital in Dublin, and for 19 years a Fellow of the College of Physicians. He is very favourably known to the profession as an author, and as one of the most erudite and intelligent physicians in Ireland, and as possessing all that fluency of expression essential to a lecturer. Dr. William Moore is also a Bachelor of Medicine of the University, and a Fellow of the College of many years' standing, and as a Physician to Mercer's Hospital, and Pitt-street Hospital for Children, has enjoyed a large opportunity, which his writings prove that he has amply availed himself of. Mr. Foot is both in years and experience very far the junior of either of these gentlemen. He has been, as yet, unconnected with any Hospital, and, so far as we know, occupies no position higher than the post of Junior University Anatomist which should recommend him for election to so important an office. It may appear superogatory for us to urge that the Chair of Medicine in a University, whose special function is the conferring of medical degrees, cannot be worthily held but by a Professor who may, in the enjoyment of the entire confidence of students and the profession, reflect the lustre of learning and experience on the school with which he is connected. We understand that an effort has been and will be made, by persons whose influence is not to be lightly considered, to put the junior candidate in the succession to Professor Banks, over the heads of senior and, in our opinion, more eligible claimants. Whether the thirty-three Fellows of the College of Physicians, with whom the selection lies, will be induced to overlook these considerations and the high character which the University School of Medicine has hitherto enjoyed—whether the Board of Trinity College will consent to so suicidal a policy as regards their Medical Faculty, we cannot pretend to foretell. We have no difficulty, however, in anticipating the feeling which such a transaction would produce amongst the profession—a universal impression of the injustice and indiscretion of the step.

The Date of Commencement of the Medical Session in Dublin.

THE Council of the Royal College of Surgeons in Ireland have, at the suggestion of Dr. Mapother, Professor of Anatomy and Physiology in their school, invited a Congress of the Medical Teachers of Dublin for the consideration of a proposed alteration in the period of opening of the Winter and Summer Sessions. Hitherto the 1st of October has been adopted for the opening of the Anatomical Departments, but as the lectures have never commenced until the first week in November, that date came to be the real time for the commencement of study. Thus, heretofore medical work has been virtually delayed for a month later than it has begun in London. This arrangement was attended with many inconveniences. In the first place, the lists for the entry of pupils' names did not close until the 25th of November, so that the student who entered on that day has less than a month of study before the Christmas recess. Secondly, Easter, which is the natural interval between the Winter and Summer Sessions, causes an interruption in the courses of lectures, and virtually came to be the period for their termination. It is now proposed to commence the courses of lectures at an earlier period, and to terminate them for the winter on the 31st of March, leaving the months of April, May, and June for the Summer Session. The proposed alteration appears to be most necessary, for, as with many students, the date at which they *will* enter on their studies is the day on which they *must*, the existent system has afforded an inducement to abridge to the uttermost the regular term of medical education.

Medical Meetings in Dublin.

THE first Monday in June approaches this year with no less interest to the Profession in Dublin than on former anniversaries. On that day every year the election of the Council of the Royal College of Surgeons takes place, and as that occasion usually brings a large number of the provincial Fellows of the College to Dublin, the opportunity is taken for the meetings of the Irish Medical Association, and the Royal Medical Benevolent Fund Society of Ireland. The progress of the Superannuation Bill of Sir Colman O'Loghlen through Parliament, under which it is hoped that retiring pensions may be provided for Poor-law Surgeons, has created a special interest in the Association meeting this year, and as the arrangements for the usual annual reunion of the Profession are being made on a great scale, a large access of its provincial members may be expected.

THE President of the Royal College of Physicians of London has issued cards for a conversazione on the 10th of June.

THE Medical Council is to meet on the 24th June.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

THE distribution of prizes and certificates of honour was made yesterday at the School of St. Mary's Hospital, by the Right Hon. Robert Lowe, M.P. There was present on the occasion Mr. Powell, M.P., Mr. Mitford, M.P., Dr. Sieveking, Dr. Sibson, Mr. Berkely Hill, Mr. John Wilson, and many others, besides a large attendance of ladies.

The Report for the year 1867-'8 having been read, the following prizes and certificates were awarded :—

WINTER SESSION, 1867-8.

Scholarship in Anatomy, value £25.—Mr. Edmund B. Owen.

Prosectorship in Anatomy.—Mr. H. F. E. Harrison and Mr. R. B. Anderson.

Prize for Students of the First Year, value £20.—Mr. Edward J. Parrott and Mr. J. F. Parsons (2nd prize).

Prize for Students of the Second Year.—Mr. Arthur Lattey and Mr. Barton (2nd prize). Certificates of Honour.—Mr. Vines, Mr. Harris (Physiology), and Mr. Butler (Physiology).

Prize for Students of the Third Year.—Mr. Hardey. Certificate of Honour.—Mr. Harrison.

Prize for Practical Anatomy.—Mr. A. E. Hayes.

SUMMER SESSION, 1867.

Prize for Students of the First Year.—Mr. George Millson.

Certificates of Honour.—Mr. R. B. Anderson and Mr. Vines (Botany).

Prize for Students of the First Year in Comparative Anatomy.—Mr. Millson.

Prize for Students of the Second Year in Comparative Anatomy.—Mr. H. F. E. Harrison.

Prize for Students of the Second Year.—Mr. Charles W. Pratt. Certificates of Honour.—M. H. F. E. Harrison, Mr. Bilham (Midwifery), and Mr. Hardey (Midwifery).

Mr. LOWE then addressed the assembly. He observed that there were considerations which ought to moderate the feeling of success, and very much mitigate the feeling of failure, because, after all, the thing they were in search of was not reward, but knowledge. He expressed his fear that the object of many who went to the Universities was to gain £200 a-year, rather than to apply themselves to the acquisition of knowledge for its own sake, and he thought one besetting danger to education in this country was that it should become sordid. Another danger was that by increasing the number of subjects to be studied it would become superficial, and the teaching itself would be deteriorated in quality. Every school should be confined to its own peculiar province of teaching, and instead of requiring students to learn chymistry and botany at the medical school, that description of knowledge ought to be previously obtained. He condemned the system of compulsory attendance at lectures. If the lecturer was a good one there would be no necessity to use compulsion; if a bad one, then to force attendance would be obliging the student to waste his time. The system of medical education as a whole was, so far as organization and uniformity of movement were concerned, in a singularly unsatisfactory state. While it was beneficial to have contests between the competitors, nothing could be so bad as to have differences existing between the examining bodies. A competition between the members of the different boards, each being anxious to engage the students, and induce them to come to their teachings, must tend to degrade the standard of the medical profession, and he suggested that the existing Medical Council should be remodelled, its numbers reduced, and its members should be the most eminent men in the professions, and that the Council should have a superintending power, and thus be able to put an end to all examinations by competing bodies. He spoke in terms of high commendation of the profession for having learnt forbearance in the administration of medicine, and for the zeal with which they had devoted themselves to promote sanitary reform all over the country. He reminded the students that their duties were not fully performed when they had studied medicine, but that they were called upon to advance the science itself by continuing the researches made by those who had gone before them. Medicine, unlike mathematics, had no definite limits, but required perpetual investigation. After some remarks on the cattle plague—the pathology of which, he complained, had received more attention than had been devoted to diseases affecting humanity—he made some good-natured remarks on the somewhat intolerant spirit shown by the members of the medical profession towards each other, and expressed a hope that a little more liberality would be evinced by them with regard to their professional differences of opinion, and concluded by wishing success to the gentlemen who had obtained the prizes which would afford them an opportunity—more valuable than any personal success—of doing much good to their fellow-creatures.

SHORT NOTES ON NICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The following notes were hastily put together by me during a three weeks' visit to Nice, in December last, with a view to their publication at the time in THE MEDICAL PRESS AND CIRCULAR. Other occupations have, however, prevented me from looking over them until this moment. If you should think them worthy of a place in your journal now, they are at your disposal.—Yours very truly,

J. STANNUS HUGHES.

24, Westland-row, May, 1868.

Nice, December 26th, 1868.

Having been afforded an opportunity of visiting Nice during the winter season (one of the severest that has occurred in the South of France for many years past), I think it may not be out of place to give your readers, many of whom are constantly, no doubt, consulted on the subject of change of climate, my unprejudiced opinion respecting this far-famed place as a winter residence for invalids.

To begin. I must say that Nice has altogether answered my expectations as a winter abode for patients suffering under certain forms of ill health, but more especially from chronic chest affections, provided a proper selection of such cases is made, and that patients will strictly adhere to the directions of their medical advisers—of which more hereafter.

The climate of Nice is wonderfully mild and sunny as compared with ours. Thus, as a general rule, from nine o'clock in the morning until near sunset at this period of the year, an invalid can, generally speaking, enjoy the open air except when it rains, which is seldom the case, or when the "mistraàl" is blowing, or in other words, when the north-west wind, deprived of its moisture, whilst passing over the lofty snow-clad mountain ranges, and deflected, is blowing strongly from the east, or the south-eastern point of the Bay of Nice, or the Point of Var, at which periods the wind is so cold and searching, and so drying up, as it were, that it is almost intolerable, even to those who, like myself, have nothing amiss with their general health.[1]

When the mistraàl is blowing, it is often accompanied by clouds of dust, which add greatly to the trying and injurious effects of the cutting wind; but, as I shall presently point out, patients can very soon, by acquiring a knowledge of Nice, and by selecting, with the assistance of their medical advisers, a suitable locality, to a great extent avoid both the mistraàl and the dust.

The best possible way, in my mind, to describe Nice as a residence for invalids, is to divide it into three *departments.*

No. 1 *Department* comprises that portion of Nice which is on the border of the Mediterranean, and extends along the Bay of Nice from Var Point to Cape de Nice, at Villa Franca, a portion of which lies between the Rue de France and the sea, about one English mile and a quarter in extent, and which has been called the Promenade des Anglais, is a terraced road (planted with palm and other trees, and green hedge-rows) for pedestrians, equestrians, and those taking carriage-exercise. Along the land side of this beautiful and sunny promenade, first-class villa residences, hotels, and boarding-houses have been built, which command charming sea views. Connected with many of the residences on the Promenade des Anglais there are handsome gardens, studded over with orange, lemon, palm, and other trees in perfection.

At the first glance a visitor is inclined to think that this Promenade des Anglais is a very exposed situation, and that few invalids could consequently enjoy it, and I admit that was my own first impression; but experience soon proves that that is an erroneous idea, and that, as a general rule, even comparatively delicate people can saunter on this celebrated promenade from eleven to three o'clock on any given day in winter, provided it is not raining or the wind is not blowing strong, especially from the south-east, east, or south-west, when prudent invalids will seek shelter in either of the two other departments, or one or other of the inland roads, presently to be described.

The easiest way to give persons who have never been at Nice at this season of the year an idea of the advantages to be gained by a residence here, is to state, that on yesterday (Christmas Day),[2] the thermometer stood at 84° Farh., at 11 o'clock A.M., in the sun, and that the promenade on the beach, which was crowded to excess, was so hot from 12 to 3 o'clock, that the majority of the people there were obliged, like myself, to shelter themselves under thin white linen parasols, from the sun's rays, and were to be seen sitting on chairs and benches under the trees, enjoying the delightful weather, whilst numerous little yachts with their snow-white latine sails, were visible in the bay, the

1 I am told that the Nizzards or inhabitants of Old Nice dread the north-west wind, but the modern parts of Nice are, to a great extent, sheltered from that wind.

2 I am informed by Dr. Trousdell, a gentleman practising here, that on Christmas Day, 1866, the thermometer at Nice was, at twelve o'clock, 96° Farh. in the sun, and 62° Farh. in the shade.

day being as genial and cloudless as the finest summer's day in Ireland; but at Nice, as in many other southern climates, an invalid must be very cautious, indeed, in his movements. Thus, he should always saunter in the sun, carry a light overcoat on his arm, a linen parasol to use when necessary, and he should invariably return to his sitting-room before sunset, for even on the finest days, just about the time the sun goes down, the air suddenly becomes not only chilly, but damp, as it did on yesterday afternoon, when a dense dew or fog could be seen over Nice from the chateau[1], just as the sun was about to disappear. It is, however, right here to state, that generally speaking, soon after sunset, the atmosphere of Nice becomes agreeable and warm again.

There is a small region of Nice called the Lazarette, which is situated close to the sea beyond the Port of Nice, called the Port of Lympia, and between the Castle-hill and the Montboran (which latter divides Nice from Villa Franca), this little favoured spot is so sheltered from all winds, that some authorities, including Dr. Pantaleone, who first directed my attention to it, consider it equal to any other place along the Riviera. There are there many pretty villa residences, and the vegetation there is the best at Nice, consequently it is a good situation for patients suffering under pulmonary consumption, who are not troubled with an irritative cough.

Although that portion of the department of Nice, which I have attempted to describe under the head of No. 1, agrees as a residence with many people who come here for health, yet owing either to the tension of the atmosphere, the almost ceaseless roll of the waves on the shore, and the noise of the displaced shingle, or from some unknown causes, some people cannot sleep there, completely losing their "rest." Indeed, several cases have been related to me, by the leading physicians at Nice, proving that such is undoubtedly the case. Thus, for instance, Dr. Travis informs me, that a very distinguished and well-known Professor of Surgery, was at Nice sometime since for his health, and took up his abode at one of the first-class hotels on the Promenade des Anglais, but did not close his eyes for the following three nights. On the fourth night he was induced by Dr. Travis to change to an hotel at Longchamp (which, together with Beaulieu, being on the same level, although a little inland, deserves to be comprised in the Department No. 1), not more than between two and three hundred yards off. That night the worthy Professor slept uninterruptedly for eight hours, but not believing it possible that *he* could be kept awake by any of the assigned causes at the hotel on the Promenade des Anglais, he returned there, and paid for his incredulity by a sleepless night, when he was but too glad to engage apartments inland for the remainder of his sojourn at Nice.

With regard to the quarters of Longchamp and Beaulieu, they lie in a low ground under the level of all the other Champses, they are flat, having been originally marshy grounds, accordingly water is found everywhere, and looking at evening down on these quarters from the mountain at Cimies you see a slight fog or mist covering them. Now Dr. Pantaleone remarks in a letter to me on the subject, "that this circumstance, which would discredit this district in any other country, makes it at Nice, where, generally speaking, there exists an extraordinary dryness of the atmosphere, a preferable abode to cases mixed with sub-inflammatory action, especially cases of sub-acute pulmonary or bronchial affections."

The 2nd department of Nice is comprised of Carabacel, formerly a pretty village, at the foot of the Nice mountains, but which has of late, by the rapid extension of the buildings of Nice, become a part of the town. Carabacel is extremely well sheltered, and is away from the sea. At Carabacel, patients with a chronic dry cough will be benefitted by a residence; here there are some excellent hotels and boarding-houses, the latter being in their charges suited to people of all means; the hotels are more moderate in their charges than those in Nice itself, or on the Promenade des Anglais; some of the Pensions or boarding-houses at Carabacel receive boarders by the week or month, at wonderfully moderate prices. For some patients Carabacel is too relaxing, and for others it is too dull—being away from the many rational and healthful attractions of Nice.

The third and last department of Nice is that of Cimies, which is situated at a considerable height above Carabacel, and is both warm and bracing, the soil being dry from position and natural drainage, and being well sheltered by the Maratime Alps from cold winds. For invalids requiring both a dry and warm atmosphere Cimies presents many advantages—its disadvantages consisting in its extreme retirement and its distance from Nice; but, on the other hand, the scenery is most lovely, and the situation in every respect cheerful, and here there are as good, if not better, residences than elsewhere, being both handsome, commodious, and not very expensive, comparatively speaking. A residence at Cimies for an invalid would almost involve the necessity of keeping a carriage. In whichever of the foregoing departments, invalids, coming to Nice for the winter, may be induced to take up their residences, they cannot be too particular in the selection of bed-rooms, and sitting-rooms, which should invariably *face the South*, for rooms with other aspects are excessively cold in this region, being shut up from the genial influences of the sun, and therefore fires are required in them, especially at night-time, whilst fires are seldom called for in rooms facing the south, except indeed in unusually cold weather.

It is important for medical men to know that there are two excellent apothecary establishments in Nice, where prescriptions are accurately compounded by qualified Englishmen, according to the British Pharmacopœia.

With respect to the out-door healthful amusements of Nice, matters of unquestionable importance in a sanitary point of view, an excellent military band plays every day (weather permitting) either in the old or new town: in the latter, the place selected, generally speaking, is the beautiful and well sheltered modern "English Garden," at the commencement of the Promenade des Anglais.

Amongst the other healthful attractions of Nice, I must not omit to mention the beautiful pony carriages, for hire by the hour or day, which are light and graceful, and by no means expensive, considering the manner in which they are turned out.

Row-boats of all kinds, and small yachts, can be hired at a moderate tariff at the harbour of Nice, and for those who like the sea, boating here in calm weather is very enjoyable.

With regard to in-door amusements, the Prefect of the Maratime Alps, who has a palatial residence here, receives visitors every week in the season, and he and his lady, as I know by experience, are very attentive to strangers; they give two or three balls during the season, which are well worth attending, when health permits. There are two excellent English lending-libraries here, where every book of repute can be had. At the Massena Club there are matinees every week in the season, from three to five o'clock in the afternoon, to which members have the privilege of inviting ladies. For gentlemen who are able to enjoy them, the clubs of Nice are a great source of recreation; lately a Casino has been opened on the Promenade des Anglais, provided with reading, conversation, billiards, smoking, concert and ball rooms, and there is a table d'hote at a moderate charge every day at the Casino during the season.

The cheap wines which are made in the neighbourhood of Nice are tolerably good, the Bellet wine being about the best. The St. George, which appears to be much used, is an agreeable drink in warm weather when mixed with water; the wine in most use amongst the English visitors is Marsala, which is both good and cheap; but excellent wines, from all parts of the world, can be procured at Nice to suit the tastes and requirements of visitors, at

1 The chateau is a fort built on a hill, 800 feet high, over the port of Nice, which commands a very beautiful and extensive view of Nice and the surrounding country.

prices not extravagantly high. There are two English "Restaurants" here, where English dishes, and English ales, &c., can be had by those who prefer them to the Continental modes of living.

I have been favoured by three physicians of high reputation, at present practising at Nice, viz., Drs. Pantaleone, Travis, and Trousdell, with letters containing their experience of Nice as a residence for invalids, which they have kindly permitted me to publish, and which I now do, believing that they will prove valuable to the profession.

(To be continued.)

SURGICAL SOCIETY OF IRELAND.

APRIL 24TH, 1868.

(Continued from page 449.)

Dr. ADAMS, President of the College, in the Chair.

AXILLARY ANEURISM AND AORTIC PATENCY.

THE PRESIDENT said—I am commissioned by my friend Dr. Machonchy, of Downpatrick, to lay before you the sequel of a case he has published in the *Dublin Quarterly Journal of Medical Science*, February, 1868. The case was headed as one of *Axillary aneurism and aortic patency*. The patient, Hugh Grant, aged 17 years, a farm-labourer, was admitted into the county Down Infirmary, 2nd of October, 1867; he was a small delicate looking lad, having a pulsating tumour in the right axilla about the size of a hen-egg, the whole arm was swollen, and of a colour approaching to livid. The tumour must have irritated, or pressed upon, the neighbouring axillary plexus of nerves; there was not only paralysis of the arm, but loss of sensation also. The pulsation of the brachial and radial arteries was weak, while on the opposite side the pulse was jerking, and abnormally pronounced. There is most remarkable visible pulsation in all the large arteries of the body; a loud double bruit de soufflet is heard, with the heart's action louder in the vicinity of the aortic opening than elsewhere, completely masking or replacing the second sound of the heart; this sound is propagated along the arteries with a gradually increasing intensity; the pulse is sharp and jerking, over 120, and seldom counting the same for two consecutive half minutes.

The history of his case was, that nine days before his admission into hospital, after a heavy day's work, mowing or using the scythe, he first observed the tumour in the arm-pit the size of a small hen-egg. He believes the swelling has since much increased in size. His state on admission was such that Dr. Machonchy feared that the cardiac and general derangements would bring about a fatal result before danger became imminent from the aneurism, so that at first treatment was directed to the cardiac symptoms. After six weeks being in hospital, the heart's action became more equable; his strength was improved, still his pulse never could be felt less than 120 since his admission.

On the 12th of November the brachial artery was found to have ceased pulsating altogether. This must have happened during the few days previously, probably from the slipping of a clot in an examination and manipulation of the tumour; the pulsation, however, was as brisk as ever in the aneurism.

During the last week in December it became evident that to longer delay active interference with the aneurism was inadmissible, as the rapid increase of size, and the thin feel of the covering, alarmed him with the idea that it was about to become a diffused aneurism. Having ascertained that the current could be stopped in the subclavian for two minutes without any increase of cardiac irritability, I determined to ligature the subclavian in the third stage of its course, which, with the assistance of Dr. W. Mac Cormac, of Belfast, and Dr. E. Nelson, was speedily accomplished on the 7th of December. On the 20th December, and the fourteenth day after the operation, the patient had an attack of epistaxis.

December 31.—Since the fourth day after the operation the pulse has been pretty constantly 104, only being 20 beats below the average at what it rated before operation; the tumour is now smaller than an hen-egg, hard, and pulseless; the arm is reduced to its normal size, there is a slight return of sensation in the forearm; when it is touched he feels a tingling in his fingers, the muscles, as yet, have not regained any power. From this period up to the 20th of January, he seemed daily to gain strength, but on the evening of this day his symptoms changed suddenly for the worse. The change seemed to be the result of mental depression caused by bad news he received, viz., that his father had emigrated and left him without seeing him, or leaving any provision for his future maintenance. On the 31st of January he died apparently from mental depression and bodily exhaustion.

Post-mortem.—The diagnosis made by Dr. Machonchy, as to the thin condition of the aneurismal sac, and as to the organic cause of the aortic patency, is proved to have been quite correct by the examining of the specimen which is here laid before this meeting. The walls of the aneurism are seen to be very thin; the contents were not composed of fibrine in concentric layers, but of coagulated blood. The heart seemed normal for a person of only 17 years of age, as to its size and proportions; there was no deposit on the lining membrane of the heart or arteries whatsoever, or nothing observable except that the valves of the aorta were completely disorganised; an atheromatous deposit occupied the free edge and surfaces of the aortic valves, and formed soft tumours nearly the size of a filbert, which must have during life floated to and fro through the area of the aortic opening. It may be seen that the disorganised valves were totally inadequate to perform their office; above the aneurismal sac the subclavian artery, both externally and internally, was perfectly healthy; when the artery left the lower part of the sac it was completely impervious and contracted. The axillary plexus was connected with the aneurismal sac, and almost identified with its walls. I have presented the specimen to the Museum of the College of Surgeons to be preserved, and with a request to the Curator that he should further prosecute the dissection, and I give his report of it which is as follows:—"I have examined carefully the specimen, and find that about three and a-half inches above the aneurismal tumour, there is a perfect obliteration of the artery for about an inch in length. Below this, for nearly three and a-half inches, the artery was quite free, and evidently carried blood up to the time of death. And just close above the tumour, apparently without any intervening space between them and the tumour, there were three arteries given off from the main trunk, the diameter of the largest of these was about one-sixteenth of an inch, the others were about the size of crow-quills, these were given off quite close together, at the same level above the aneurismal tumour: there is no positive evidence from the specimen that these arteries communicated with the sac.—JOHN BARKER."

The great question before the society appears to me to be whether operative surgery is in danger of being brought into disrepute by the tying of a large artery of an extremity, with a view to cure an aneurism, when there exists in the patient the organic disease which Sir Dominic Corrigan, I believe, was the first to describe, and has denominated permanent patency of the aortic valves. As to the case before us, it would appear that nothing could go on for a time after the operation better than the aneurism; the ligature came away without any hæmorrhage in the usual time; the aneurism was in process of perfect cure; the paralysis was better; the pulse fell from 120 the day after the operation 20 beats, and the report for 14 days was favourable, when depressing causes and mental distress seem to have produced asthenic symptoms, and the patient died in an exhausted state. It must, however, be recollected that even without the influence of such causes as acted here, that death in cases of this disease of the aorta frequently occurs in this manner. The maxim, much commended by the celebrated Percival Pott, "*anceps remedium est melius, quam nullum*," applies in this case. For my part, I believe that in cases of an aneurism of one of the large arteries of an extremity, when complicated with the alteration of the aortic valves called "permanent patency," our prognosis must be most unpromising. I do not dread the refluent stream after the ligature has been made, as the source of mischief likely to ensue, but I have always seen the general health of a patient with inadequacy of the aortic valves, to be very delicate, and generally have observed such patients to be very bad subjects for any surgical operation whatever. I take this opportunity of laying before the society the preparation of a heart which had this atheromatous and soft warty condition of the aortic valves, which exactly resembled the appearances noticed in Dr. Machonchy's case. The patient had a popliteal aneurism, which, notwithstanding that the existence of the aortic disease was well diagnosed, still the operation for the popliteal aneurism was proceeded with; but the result was unfortunate. The patient was weak and had adynamic symptoms after the operation, and the wound made to tie the artery in Scarpa's space, near the groin, did not heal, but, on the contrary, abscesses formed in the thigh and leg, and the patient after a month fell a victim to the extensive suppuration which ensued. There might have been something in the operation itself which, in this case, was not happy; and

there might have been delay in dissecting down on the artery; but the extensive suppuration, in my opinion, in this case, which occurred now many years ago, arose from an unhealthy asthenic state of the system, caused by the valvular disease in question. I see present by me my colleague, Dr. Fleming, however, who may, perhaps, relate to the society the case of a patient of his in the Richmond, who had a carotid aneurism, and this was complicated, he thought, with this very condition of the aortic valves; yet the favourable result of the operation in this case may, perhaps, be considered as bearing operative surgery out in not being deterred from deligating a large arterial trunk, even when the aneurism, for which the operation is resorted to, is found in a patient who has also the unhealthy complication of the disease of the aortic valves we are alluding to. All I have to say is that there may be cases of this kind in which the deligation of a large artery may be deemed necessary, but I would wish to express my conviction that such cases are most unpromising subjects for active surgical interference, and are only to be justified, if at all, by Percival Pott's maxim, "*anceps remedium est melius quam nullum.*"

Dr. FLEMING said the age of the individual referred to by the President, was three times that of the patient in Dr. Machonchy's case. He had a carotid aneurism of the left side, occupying the whole of the space between the angle of the jaw and the clavicle. No second opinion could be entertained as to the existence of aortic patency. He had repeated attacks of syncope, great prostration; notwithstanding such unpromising symptoms the carotid was tied, and with success; and he had seen the man two or three years afterwards, at Holyhead, apparently in very excellent health; the physical signs alluded to, of aortic disease, being, however, distinctly marked. The artery was tied in the first portion of its course. It was of enormous depth, and he had considerable difficulty in securing it. He should add, that there were casts of the patient at Richmond Hospital, both before and after the operation. In many cases when aneurism was cured, particularly in popliteal aneurism, the site of the aneurism was a permanent tumour. This was also the case with the patient to whom he referred. The whole of the tumour did not subside; but all pulsation ceased, the ordinary signs of aneurism disappeared, and the tumour became quite soft.

Dr. CROLY observed that the late Mr. Colles, in dealing with this subject, distinctly stated that if the *sac* of the aneurism collapsed, when the ligature was applied to the artery leading to it, it was not a favourable symptom.

The PRESIDENT observed that on a former occasion he had mentioned the great importance of illustrating the cases brought forward, by photographs and casts. He had also mentioned that it was possible he might be able to procure a copy of the beautiful photographs of surgical cases during the late American War, which had been exhibited in Dublin lately by some clever and enterprising American surgeons. He did not despair of obtaining them. Dr. Mapother had written to America for them, and it was probable the request would be complied with. The President then alluded to a book which he had received from the Surgeon-General of the United States, and which he now presented to the College, containing valuable illustrations of surgical cases. One of these especially attracted his attention. It was the case of a penetrating wound of the abdomen, of which two views were given. By placing a glass behind the patient, a reflection of the posterior view of the wound was obtained; the orifice of penetration and the orifice of exit in the cases of gun-shot wounds were very different, and it was interesting to obtain a view of both in the same drawing, by this very ingenious contrivance. There were other illustrations showing different cases of successful operations in the amputation of the hip-joint. He remembered telling one of the American surgeons of an observation of the late Surgeon Wilmot, one of the best surgeons in Ireland, in his day, that in his experience in the case of artizans in Dublin, who got compound fractures of the thigh, there were very few recoveries; and he asked the American surgeon, how he could explain the remarkable success of the treatment of compound fractures of the thigh during the American War. The reply was, that the metropolitan artizan could not be fairly compared to the American soldier. The men in the army were well fed, well taken care of, both before and after the operation, and were the finest men, as to bodily health, that could be found. Injuries were therefore sustained by them, under which the broken down metropolitan artizan would sink. The President then brought forward a remarkable case of chronic rheumatic arthritis, which will appear in our next number, with his concluding observations.

Correspondence.

THE MEDICO-POLITICAL ASSOCIATION AND MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not know what the aims of the recently formed "Association" may be; but I would suggest that it should strive to attain—(1) One degree called M.D., similar to the Paris one, granted by State examiners in different parts of the kingdom; (2) Payment of medical officers of the Poor-law in the same manner as clergymen, &c.—*i.e.*, a sum sufficient to enable them to devote their whole time to their important duties; and (3) appointment to all public medical situations to be made by open competition (*concours*). Lastly, the Association should encourage practical medical men to become members of Parliament more than they have hitherto been. Has the Association the idea of trying for such grand aims!—I remain, sir, yours, &c.,

CHARLES DRYSDALE.

Southampton-row, W.C.,
May 18th, 1868.

DEAF MUTISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The medical history of deaf mutism, or the kowledge of its beginning, not being known to the profession, will you oblige me by inserting in your columns the following correspondence, showing an official obstacle to the first step in acquiring information necessary to the establishment of fundamental principles, in order that we may adopt curative means for the deaf mute.—I am, Sir, faithfully yours,

WILLIAM PARKER.

Bath, 19th May, 1868.

[Copy.]

To George Graham, Esq., Registrar-General, Somerset House, London.

SIR,—Permit me respectfully to address you in behalf of the deaf and dumb in this country. Having studied their condition during the last thirty years, and finding that no medical treatment to cure them is adopted either before or after admission into the deaf and dumb institutions, I beg to suggest the necessity of registration of infants at a month old, whether deaf or not. By this plan the first and only means of acquiring their real state can be known.

Dr. Scott, of 30 years' experience of the Exeter Deaf and Dumb Institution, writes to me and says:—"*The deaf mutes which are received are supposed to have exhausted curative means, and my attention has been almost solely directed to the best means of instructing them.*" If we do not begin at the beginning of life, it is impossible to have correct and efficient statistics and proper means adopted to cure them, particularly as disease of the ear, the result of infantile diseases, namely, teething, scarlet fever, small-pox, whooping-cough, and measles, is the chief cause of the calamity. The public should commence their knowledge of the deafness at a month old of every infant, and the medical profession should begin their curative process as soon as the deafness from the named diseases arises at two or three years of age. It is contended that no more attention comparatively is now paid to this class of sufferers, than was paid to the lunatic before M. Pennel's liberation of their chains, forty years ago. The absence of any register and the absence of any medical treatment of deaf and dumb infants, are palpable deficiencies and evidences of want of proper regard of them. This has not been disputed by the profession, on the contrary, full concurrence by professional men has been awarded to my propositions, and a hospital for their cure should be established in a central situation, near a railway, of a mild and healthy locality.—I have the honour to be, Sir, your obedient servant,

WILLIAM PARKER, M.R.C.S., L.A.C.

2, Lynwid Villa, Bath, 4th May, 1868.

The proposed registration is suggested to be entered in the present Register by an additional perpendicular line, headed "Hears," "Deaf," and noted H. or D. as the case may be.—W. P.

5th May, 1868.

SIR,—I have to thank you for your observations on the deaf and dumb in this country. I cannot adopt your suggestion as to the record to be made in the Register, without an amend-

ment of the present Civil Registration Act relating to births.—I have the honour to be, Sir, your faithful servant,

GEORGE GRAHAM, Registrar-General.

W. Parker, Esq.

THE TWENTY-FIFTH REPORT OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have received the twenty-fifth report of the Council of the Royal College of Surgeons in Ireland, and I have also read Dr. Hamilton's letter in your last number.

As a Licentiate and Fellow of the College, may I take leave to say the report appears to be a meagre and unsatisfactory document, and does not contain any single suggestion for the improvement of our profession.

I had hoped (in common with many of my brethren, Fellows of the College, residing at a distance from Dublin) that some mention would have been made of an intention to apply for a new charter.

In common justice to us, whose monies have been received by the College, we should have the privilege of voting at elections, either by proxy or voting-papers; as matters are now arranged, we have no voice whatever in the government of the college.

In the financial statement I observe the sum of £261, 4s. 3d. expended for school expenses. I am at a loss to understand why College funds should be so expended, and why the College school should be supported out of College funds, to the detrement of the private schools in the City of Dublin.

I hope some independent Fellow of the College will take these matters in hand, and bring them before the annual meeting on first Monday in June, which I would certainly do could I be present.—Your obedient servant,

THOS. H. BABINGTON, M.D., F.R.C.S.I.

Londonderry, May 22, 1868.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 19th inst., viz. :—

Messrs. W. J. Mason, Sudbury, Suffolk; T. C. H. Spencer, L.R.C.P. and L.S.A., Wokingham, Berkshire; Henry Gould, L.S.A., Gravesend, and R. E. Grigson, Watton, near Thetford, Norfolk, students of Guy's Hospital; D. K. Robertson, L.R.C.P. and L.S.A., Westbourne-park Villas; J. E. Pierce, L.S.A., Gelwern, near Abergavenny; D. H. Goodsall, Gravesend, and F. W. Langworthy, Plympton, Devon, of St. Bartholomew's Hospital; W. P. Lee, Sydney, New South Wales; H. H. Spratt, Wairarapa, New Zealand, and J. W. Harrison, Barnsley, Yorkshire, of the Middlesex Hospital; E. B. Owen, Cleveland-square, Hyde Park, of St. Mary's Hospital; R. A. Jamieson, Pekin, China, of the Cork School; F. B. Besly, St. Martin's-court, Leicester-square, of the Charing-cross Hospital; F. T. Le Tall, Woodhouse, near Sheffield, of the Sheffield School; J. A. Rayner, Highbury New-park, of King's College; and E. W. Spragge, Toronto, Canada, of the University College and Toronto Schools.

On the 20th inst. :—

Messrs. A. G. Cuffe, Woburn-place, and E. A. Phillips, Eling, Hants, students of University College; Frederick Waterhouse, Bolton, Lancashire, of the Leeds School; Ratcliff Nuttall, Bury, Lancashire, of the Manchester School; J. C. Thornicraft, Clapham, of the Charing-cross Hospital; John Johnson, L.S.A., Darlaston, of the Birmingham School; Edward Stephens, Ilminster, of the Liverpool School; M. W. Rice, M.B. and C.M. Edin., Sloane-street, of the Edinburgh, St. George's, and Middlesex Hospitals; John Glanvile, Wedmore, Somerset, of St. Bartholomew's Hospital; F. C. Vines, L.S.A., Vasse, West Australia, of the Dublin School; Edward Young, Hawkhurst, Kent, of King's College; and Armand Leslie, Battersea-park, of the Middlesex Hospital.

REPORT OF MEETING OF COMMITTEE OF COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.—Held at Birmingham, April 23rd, 1868.—Resolved—1. That the following gentlemen be appointed officers of Sections :—Medicine.—*President*, Sir W. Jenner, Bart., M.D., F.R.S., London. *Secretaries*, E. L. Fox, M.D.Oxon., Clifton, Bristol; William Roberts, M.D., Manchester. Physiology.—*President*, Professor Rolleston, M.D., F.R.S., Oxford. *Secretaries*, W. L. Church, M.D.Oxon., London; Professor Beale, M.B., F.R.S., London. Surgery.—*President*, James Paget, Esq., F.R.S., London. *Secretaries*, T. P. Teale, M.A., M.B.Oxon., Leeds; W. Stokes, junior, M.D., Dublin. Midwifery.—*President*, Sir C. Locock, Bart, M.D., F.R.S., London. *Secretaries*, J. G. Wilson, M.D., Glasgow; J. G. Swayne, M.D., Clifton, Bristol. State Medicine.—*President*, J. Simon, Esq., F.R.S., London. *Secretaries*, J. E. Morgan, M.D.Oxon., Manchester; T. J. Dyke, Esq., Merthyr Tydvil. 2. That a Sub-committee be appointed to consider and to report as to the proper subdivision and organisation of the various Sections, and the best mode of appointing their officers; and that the Sub-committee be requested to observe and report upon the working of the different sectional meetings at Oxford. The Sub-committee to consist of the following gentlemen, with power to add to their numbers :—The President; the President-elect; the President of the Council; the Treasurer; the General Secretary; the Officers of Sections; Mr. Cordy Burrows; Dr. Paget; Dr. Edward Waters; and Dr. Wilkinson. 3. That the report now read from the Committee for considering the Representation of the Profession in the General Council of Medical Education be adopted; and that the members of the Sub-committee, with the President of the Council, be appointed a deputation to wait upon the Medical Council.

REPORT OF THE SUB-COMMITTEE APPOINTED TO CONSIDER THE REPRESENTATION OF THE PROFESSION IN THE GENERAL MEDICAL COUNCIL.—The sub-committee, in accordance with their original recommendation, supported by the almost unanimous vote of the Association, agreed to at the anniversary held in Dublin in 1867, are of opinion that the profession will not be adequately represented in the General Medical Council, as at present constituted, by less than eight representatives, to be elected by the registered members of the profession resident in the United Kingdom of Great Britain and Ireland, with the exception of those on active service in the army and navy. The sub-committee are of opinion that the addition of eight members to the General Medical Council as representatives of the profession generally, far from embarrassing the proceedings or militating against the influence of the Council, will, on the contrary, have the opposite effect. The sub-committee entertain no doubt that the profession, on which the payment of the representatives of the various medical and surgical corporations and of the nominees of the Government at present rests, will willingly pay the additional cost of their own representatives. At the same time, the committee think the propriety of paying their own representatives by the various universities, colleges, and corporations, is an object for the consideration of the council. The sub-committee are of opinion that, if the Council, in consequence of the addition of the members to be elected by the profession, should deem it advisable to recommend a diminution of the number of the representatives of the corporations, a corresponding reduction may then be made in the representatives of the profession.

QUACK DOCTORS AND THEIR VICTIMS.—Last week an inquest was held by Mr. Humphreys at the Black Bull Tavern, Lever-street, St. Luke's, on the body of a married woman, named Susannah Irwin, 38 years of age. Alfred Irwin, the husband, deposed that on Sunday week the deceased felt ill, and the next day she went for a doctor, but did not see him. Witness thereupon sent for Mr. Denase, a French gentleman, who practised as an herbalist and botanist. He saw the deceased, and at five o'clock he came again, bringing with him two bottles of medicine and a large number of pills. He told her to take a glassful of the contents of one bottle every half hour, and of the other every hour, and gave her 26 pills to take at frequent intervals during the night. By six o'clock on Tuesday morning she had taken the two bottles of physic—33 doses—and 26 pills. Not feeling better, she sent for the police surgeon, Mr. Garrard. She had a miscarriage after she took the medicine. He did not think that she would take medicine to procure miscarriage. Guillaume Denase—I was an herbalist, but I am now carrying on business as a botanic chemist. On Monday last I was called twice to deceased, because Dr. Bewley could not attend her. I was related to her, and at five o'clock I took her her medicine in a friendly manner. She was suffering from a pain in the chest, and from inflammation of the chest and lungs altogether. I prescribed half an ounce of yarrow, half an ounce of centuary, the same quantity respectively of agremony, St. John's wort, and ginger-root, and a quarter of a teaspoonful of powdered cloves, all infused in water. I ordered a wineglassful to be taken every half hour. I ordered her pills at the same time. They consisted of 20 grains of cayenne pepper, 20 grains of lobelia powder mixed with honey. I could have taken the whole dose myself. I also ordered her a mustard poultice, a

hot bath, vinegar clothes, hot water bottles to her feet, and plenty of blankets. I do not understand accouchements, but I never asked whether she was *enceinte*, and I would have treated her in just the same way, whether or no. Mr. F. A. Grant, pathological anatomist, said that he had made a post-mortem examination of the body. Throughout the whole of the organs there was no trace of inflammation or of any disease. There had been a miscarriage. There was no natural cause for death. The medicine and the treatment of Mr. Denase had caused the miscarriage, the exhaustion from which resulted in death. The Jury returned the following verdict :—That the deceased died from exhaustion resulting from a miscarriage, which had been brought on by medicine taken inadvertently that had been ignorantly prescribed for her by an unqualified practitioner; and the jury desire to express their regret that ignorant and unqualified practitioners are allowed to prescribe for patients to the danger of life.

CONTAGIOUS DISEASES ACT.—A memorial has been presented to the Lord President of the Council, signed by Dr. Alderson, F.R.S., president of the Royal College of Physicians, Mr. J. Hilton, F.R.S., president of the Royal College of Surgeons, and other distinguished medical men, to the effect, that in the opinion of the memorialists, the principle of the Contagious Diseases Act, 1866, should be extended to the civil population by providing proper hospital accommodation for women suffering from these diseases, and giving power for their detention in hospitals. These measures, it is urged, do not involve a system of licensing prostitution ; they are intended to be purely restrictive and sanitary in their operation. The objects of the memorial are heartily approved by Dean Stanley, the Vice-Chancellor of Cambridge and Oxford, Canon Selwyn, and by Admiral Sir W. F. Martin, Major-General Murray, and Sir John Bowring.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.—Examinations, 1868.—Senior Scholarship in Medicine, Surgery, and Midwifery—A. F. Field, T. H. Hendley. Senior Scholarship in Anatomy, Physiology, and Botany—H. Alder Smith, A. E. Cumberbatch ; Bentley prize—W. Deane Butcher; Kirkes medal—A. F. Field. Practical Anatomy, Senior—Foster prize—A. E. Cumberbatch, H. Alder Smith, C. F. Gray, F. H. Bodmin, G. P. Skrimshire, S. G. Sloman, W. G. Lowe, G. S. Payne, P. B. Stoney, H. Symons ; Wix prize—A. F. Field; Hichens prize—A. F. Field. Practical Anatomy, Junior—Treasurer's prize—W. J. Walsham; Examiner's prize—A. H. G. Doran, C. J. Newton, G. A. Phillips, W. R. Smith.

THE VOLUNTEER MEDICAL SERVICE AT WIMBLEDON.—The spring meeting of the National Rifle Association was held at Willis's Rooms on Thursday, May 21st—his Royal Highness the Duke of Cambridge in the chair. The Council had omitted in its report to take notice of the dissatisfaction which exists among the medical officers, with regard to the composition of the hospital staff at Wimbledon. Dr. Carr, therefore, moved, and Mr. Squire seconded, a resolution to the effect that, in the opinion of the meeting, the volunteer medical staff at Wimbledon should consist of, at the least, one full surgeon, and one assistant-surgeon, and that the hospital for volunteers, and that for the regular forces, should be distinct. The distinction being that which exists between two regimental hospitals in the field, the senior army surgeon would have the position of principal medical officer as in the regular army. An irrelevant discussion arose as to the fate of any volunteer who might sustain a gunshot wound ; the lay parties to the discussion being evidently unaccustomed to the amenities which obtain in the higher walks of medical practice, otherwise they would have known that in every case of doubt or difficulty, or of exceptional importance, medical men are only too glad to avail themselves of the special experience of their compeers. It is somewhat a matter of surprise that its honorary surgeon did not advise the Council of the National Rifle Association to that effect. The motion was withdrawn, his Royal Highness the Duke of Cambridge stating that the matter seemed to him to involve general questions of volunteer organization, and was, therefore, one for the consideration of the War-office.

MEDICAL CLUB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have recently received a large number of letters of inquiry, respecting the Medical Club, and lest any should inadvertently have remained unanswered, I hope you will allow me a short space in your columns to announce that the Club has removed from the temporary rooms hitherto occupied in Pall-Mall, to more central and convenient premises, situated at No. 9, Spring-Gardens, overlooking Trafalgar-square.

The new club-house will afford increased and improved accommodation for the members, and has been placed under the management of Mr. Webb, Jun., late of the Carlton Club, who will reside on the premises. I have every confidence the comfort and convenience of the members will receive Mr. Webb's constant and careful attention, and that all will have good reason to be satisfied with the changes that have been made.—Your obedient servant,

LOBY MARSH, M.D., Hon. Sec.

CLINICAL LECTURE ON THREE CASES OF ANOMALOUS RHEUMATISM.

By C. HANDFIELD JONES, M.B.Cantab., F.R.S.,

PHYSICIAN TO ST. MARY'S HOSPITAL.

Gentlemen,—As medical practitioners engaged in the work of conserving the health of human beings, as far as we are permitted, we cannot regard disease otherwise than as an anomaly; a result proceeding in some way or other from infringement of the laws of health. I would not contend, however, but that from a stand-point of wider view than that of the mere physician disease may be considered as a necessary part of that great providential scheme under which we are all placed, of which the main intent, so far as our dim ken can read it, seems to be the subjecting man to a probation more or less severe, to a testing which shall show what each individual is, whether dross or ore. Of our diseases it may often be said, with the older divines, Πάθημασα μαθηματα, and if they fulfil so high a purpose, they cannot be considered as unimportant or noxious accidents, interrupting an otherwise harmonious arrangement. But returning to my original statement, I wish to remark to you that, although disease be itself an anomaly, yet it has a regular, lawful, and orderly method of procedure, which it ought to follow, and which, in the great majority of cases, it does follow more or less closely. Deviations from this rule or norm of pathological action are, however, by no means infrequent, and have long attracted the attention of physicians. They constitute the so-called *ataxic* phenomena, which are well-known and dreaded by experienced men.

These you must distinguish from such as are proper and ordinary to the disease, but which threaten or destroy life by their excessive severity. You will understand the distinction better by a few examples. A patient may have small-pox of great gravity, may be brought into exceeding danger by the secondary fever, pneumonia, œdema of the glottis, or by deep-seated suppurations, but yet there is no ataxia. If, however, about the 6th or 7th day, all at once, without apparent cause, the patient's strength gives way, and alarming nervous disorder supervenes in the form of delirium, coma, anxiety, depression, dyspnœa, without any appreciable thoracic affection, we have too much reason to expect a speedily fatal termination. These symptoms are anomalous, they are not in accordance with the usual course and character of variolous fever, they are ataxic. Another symptom of the same class is hæmorrhagic effusion taking place from cutaneous and mucous surfaces, as in the variety termed "variolæ nigræ." Nothing of this kind ought to occur in even the severest regular small-pox, it is an anomalous symptom, and therefore grave.

Again, a patient suffering from pneumonia may have delirium, and be otherwise gravely ill—in fact, may die, (as a poor fellow did who sank about three hours after he was admitted, and in whom we found the whole of the right lung in a state of gray hepatization, while the left was also somewhat inflamed,) and yet there is no ataxia, no anomaly. But if during an epidemic of pneumonia one person sickens no more severely than several others as regards the extent and intensity of the inflammation, but nevertheless becomes delirious at a very early period, and has an extraordinarily rapid rate of breathing, so much that the respirations equal or exceed in frequency the pulse-strokes, this man has ataxic or anomalous pneumonia, and is in much greater peril than another whose lung inflammation may be twice as extensive, whose temperature is higher, and pulse more accelerated, but whose nervous system remains comparatively undisturbed.

An attack of acute articular gout may be painful and distressing enough, but so long as it remains confined, as it normally should, to the articulations, it is not perilous. When, however, it becomes anomalous, and leaving more or less completely the articulations, attacks the brain or the heart, it brings life into exceeding jeopardy. Rheumatic fever, so long as it preserves its normal character, confines itself to the articulations, synovial sheaths, or fibrous membranes; when it assails other parts it becomes more or less anomalous.

These remarks may serve as an introduction to two cases which have recently been in the hospital, in which rheumatic fever presented sundry peculiar phenomena, constituting well-marked aberrations from its regular course. Such occurrences are by no means infrequent, and you should be prepared to encounter them.

Case 1.—W. H., æt. 24, admitted February 7th, 1868. The next day the following notes were taken. According to his own account (which cannot be implicitly relied on, on account of his mental state) he has been ill about a week. Is of fair complexion, pale face, skin moist and hot; perspiration acid and rheumatic; tongue furred, yellow, and moist. Complains of pain in feet, at present there is

no swelling of any joint, but yesterday the left wrist was notably inflamed. The right foot is strongly curved inwards, and the dorsum twisted so as to look upwards and outwards; both feet are very painful when moved. None of the muscles of the right leg are rigid as far as can be made out, possibly those at the inner side of the foot may be. Heart's sounds normal; passes all his urine in bed, was very talkative and delirious during the night; at present is rational enough to answer questions properly; pulse 80, of tolerable force and size; eyes clear and bright; a trace of eruption on fore part of chest. Potassii iodidi, gr. i. + mist. potass., citrat.-efferv., ℥iss., 3tiis horis. Pulv. ipecac., gr. ij. + morphiæ muriatis, gr. ½ + extr. hyoscy., gr. iv. in pil ij. *h. n.*

9th.—Much delirium all night, was not vomited by the first pill; was quieter after he had a second without the ipecacuan; pulse 93, of good force and volume; has taken his dinner well; has been more rational since ten A.M.; heart's sounds normal; pulv. ipecac., gr. xx., vespere si opus sit; repeat pil. morph.

10th.—The emetic was taken, but it only acted on the bowels; he then took the pill and slept well; had a very quiet night; urine this morning clear, acid, of lightish colour; respiration 18, asleep; pulse 80, not weak. Complains of pain in back, says that all his lower limbs from loins downwards are set fast, so that he cannot move them; the right knee is straight, and the muscles are rigid, it gives him great pain if I use any force to flex the joint; the left is partly flexed, and is also held rigid; he cannot bear to have it extended. Both hips are also set fast by contracted muscles. The right ankle is mobile, the left tender; both feet are now curved inwards nearly alike. Has been asleep all day; temperature 100°; atropiæ, one-fortieth of a grain, to be injected subcutaneously; repeat pil. morph. si opus sit.

11th.—Passed a good night, did not need the morphia; pain in loins severe, prevents him from turning; does not seem to be notably increased by pressure; says his legs feel so weak, but his knees are much less rigid; C.C. ad lumbos ad ℥iij.; repeat atropia injection. Pt. mist. *ter die.*

12th.—Pain in back much less; has good sensation in legs, and can move them, but not well. There is scarce any trace of rheumatism anywhere; the ankles bear passive motion. Potassi iodidi, gr. iv. + dec. cinchon, ℥i. *quater die.*

13th.—Is doing well; can move legs better.

15th.—Can move left leg well, but the right knee is stiff and intolerant of passive motion.

17th.—Right leg almost completely flexed; the hamstring tendons are stiff, and he cannot bear extension; urine pale and clear; atropia injection, adde tr. valerianæ ℥i. ad ℥i. mist.

21st.—Getting much better.

25th.—Is getting on very well; can walk about, but feels very weak; requests remedies for a urethral discharge which has existed since about the middle of last December. The discharge was puriform, and there was balanitis to some extent. A goulard lotion, and chloride of zinc injection, pretty well got rid of these troubles; he was then ordered citrate of iron and quinine, with tr. nucis vomic, and left the hospital in very fair case March 3rd.

It may be questioned whether this was a case of gonorrhœal, or of simple rheumatism. I do not think that it matters much which we regard it, but my own belief is certainly that it was the latter. Delirium is not, as far as I am aware, ever met with in gonorrhœal rheumatism. I shall defer saying anything farther about the delirium till we consider the next case, but I will ask your attention to the lumbar pain, and the tonic spasm of the lower limbs. These symptoms set in markedly, just after the disappearance of the delirium, although it is true that on his admission there was evidence of similar spasmodic action about the right foot. I believe we shall not be far out, if we regard the spinal symptoms as the equivalent of the cerebral, both on account of their order of succession, and their supervening under the same circumstances. We can hardly think that there existed any cerebral meningitis, though probably there was some amount of intracranial hyperæmia. Neither is it likely that there was any actual spinal meningitis, but only more or less irritation of the lumbar enlargement from whence the nerves of the lower limbs are given off. The unknown cause of rheumatism acting on the hemispheres disordered their function, that of duly subserving the mental actions, and thus the patient had delirium. In a like manner, it acted on the lower spinal centres, deranging their function, that of acting harmoniously with the voluntary motor centres, and by morbidly stimulating the nerve-cells of this part gave rise to tonic spasm. The lumbar pain was caused by a state of the sensory nerves, homologous to that which conditioned spasm in the motor. Although I believed that the spinal symptoms proceeded mainly from rheumatic irritation, I thought it quite necessary to act on the more unfavourable view, viz., that meningo-myelitis if not actually existing was yet imminent, or at least to be feared. You know that it is in medicine as in warfare, some posts have to be fenced and defended with extreme care, not on account of their magnitude, but because of their importance to others, and because if once lost they can with difficulty be regained. The loss of a few ounces of blood was, even if unnecessary, a trivial damage, compared to that which would have occurred from allowing inflammatory mischief to establish itself unchecked in the delicate tissue of the cord and its nerve-roots. Two or three days continuance of such morbid action, might have done damage which years would not have repaired; and it was therefore only prudent to act, as you should in all like cases, and ensure your patient, as far as possible, against threatening or possible evil by timely precaution. The cupping was decidedly beneficial, and we have no cause whatever to regret the small loss of blood. I hope you will never allow yourselves to be so led away by the too prevalent hœmatophobia, as to neglect the old practice of letting blood when occasion requires. With most persons a few days good feeding will replace the blood-cells which you have abstracted, while many weeks or months might not avail to repair the textural damage, which unrestrained inflammation may inflict on a delicate organ. I hope, also, you will not neglect to become skilful cuppers, it is often preferable to abstract blood in this way rather than by leeches. The atropia injection was evidently useful; I believe it was repeated five or six times, and I am rather surprised that it did not produce more evident effects on the pupil, or the throat. A third of the quantity injected constitutes an efficient dose, to be taken at one time, which I should not like to exceed in most persons; and as the energy of a drug administered subcutaneously is much greater than when it is given by the mouth, I should not have ventured on so large an amount, had I not known that as much or more had often been used in the same way by others. It was given as a direct sedative to the excited nerve-tissue of the cord. You may be assured that such phenomena as occurred in this case are very rare in rheumatic fever. Cerebral disturbance is often witnessed, but the spinal centres seem far less prone to be similarly affected. I think you cannot but observe in this case, how mild and slight the articular inflammations were, not more, indeed, than was just sufficient to make us certain what we were dealing with. In fact, at the outset, I was half inclined to question whether the disorder was not largely exaggerated. I may mention that I have recently seen a case of the affection, termed by Trousseau tetania, which he in common with other French observers regards as of "rheumatic nature." The disorder is by no means rare in France, but this case is the first I remember to have seen. The patient was a young girl, both whose hands became cramped and fixed in a slightly flexed position one day while she was washing. The disorder did not affect other parts, and disappeared of itself the following day. Though this child's case and the one I have related are separated by a long interval, there is an evident resemblance between them, the tonic spasm being in both almost

certainly of rheumatic origin. That the cause of rheumatism acts often in a very special manner on some department or other of the nervous system seems to me unquestionable, and the knowledge of this fact may sometimes throw light on neuroses, whose causation would otherwise be very obscure. In proof of this, let me refer you to a case which I have published (v. *British Medical Journal*, 1866, November 3rd) of concurrent chorea and delirium, both being sufficiently severe, and the rheumatic nature of the whole malady being evidenced by the discovery of a mitral murmur during life, and of endœcorditis after death. Here the brain and cord suffered quite in a like way, the motor disorder in the one being the equivalent of the intellectual in the other. Very probably had our patient W. H. been a female, the functional derangement of his cord would have assumed the guise of chorea, rather than of tonic spasm.

Case 2.—Lewis H., æt. 31, groom, admitted December 11, 1867. Had rheumatic fever 10 or 11 years ago. Health fairly good since that time. Ill now since December 8th, when it was very cold and snowy. First felt pain at chest, it has extended all over him, and now the hands, ankles, knees, and loins are affected, as well as the arms and shoulders. Heart's sounds normal. Urine, spec. grav. 1020, fully acid, has been, and is, very scanty. Profuse perspiration. Bowels not open. No appetite; much thirst. Pil. hydr. c. coloc. gr. 8 statim. Pot. bicarb. ʒss. + pot. nitrat. gr. x. + M.C. ℥i. 4tis horis.

14th.—He appeared to be going on fairly well all yesterday, but has been very delirious since 2 A.M., wandering very much, and wanting to leave his bed. Is sufficiently conscious to answer questions now. Expression of countenance indicative of excitement and mental confusion, gaze rather intent; bowels open; tongue slightly coated, and moist; pupils rather large, equal; skin moist and perspiring; pulse 102, soft, regular; urine very thick with lithates, not albuminous, spec. grav. 1034 yesterday. A dull red, spotty eruption has appeared on neck and front of chest, and to a less extent on the abdomen. Pot. bicarb. ʒi. + M.C. ℥i. 2dis horis. Opii gr. i. + pulv. colchici. gr. v., in pulv. 4tis horis. Milk O. i., brandy 6 oz.

15th.—Was very delirious in the night, but not so much so as the previous night. Pulse 120, large, excited. Answers questions, says he is ever so much better, is inclined now to sleep; is very thirsty; tongue very baked and dry in a broad median stripe; temperature 104° ; eruption is extremely copious on the abdomen, and very much so on the chest and on the back; it is present on the arms, but not on the thighs or legs at all. It consists of low papulose elevations of small size, and of ill-defined maculæ closely crowded together. It has a good deal of resemblance to the eruption of typhus, but the aspect of the patient's face is not dull, heavy, and confused, as in that fever; pupils not so large as yesterday; no dulness in the back, but air does not enter freely, and there is some obscure râle; rheumatism has left the limbs.

16th.—Pulse 108, of fair force; tongue dry, especially in the middle; forehead rather hot; eyes not injected; has been very restless and delirious; likes his brandy; urine = 34 oz. in 24 hours, red, deposits lithates; eruption faded to some extent on the abdomen, the papules are more elevated; takes milk O. ij., temperature = 104°·5. Ant. pot. tart., gr. ¼ + aq. ʒi. *o. h.*

17th.—Pulse 110, of good size, and tolerable force, soft; tongue dry; bowels open; urine clear; no vomiting; abdomen much distended by flatus; eyes tolerably clear; head has been shaved and cold applied; has had 26 doses of his mixture; was a little quieter after an opiate enema last night, wandering much, but did not try to get out of bed; answers questions pretty sensibly; likes the cold lotion; pupils of moderate size. Ant. pot. tart., gr. ½ + mist. potass. citrates ʒiss., *quater die.* Repeat enema, cold effusion to head, ten minutes at a time, twice a-day.

18th.—Was sick, and vomited before the first cold effusion, has had no vomiting since; tongue moist, coated. Had, this morning, a dose of calomel and colocynth, aa. gr. iv.; was quieter in night; pulse 105, large, soft; some show of rheumatism in wrists; eruption has faded very much; heart's sounds normal; temperature = 38°·4 (101·12). Repeat mistr., enema opii., and cold douche.

19th.—Says he is a great deal better; had a pretty good night, is less delirious; bowels open; no vomiting; pulse 96, soft; temperature same; rheumatism very slight; is much better after the cold douches, rather likes them.

20th.—Pulse 87, soft; some distinct sudamina on belly and chest; is drowsy; takes nourishment well; temperature 100·7; heart's sounds weak. Vini. ipecac. ℥ 8 + pot. iodidi gr. iss. + spt. œth. chlor., ℥ x. + tr. hyoscy, ℥ 20 + mist. potass. citrat. ʒi., *quater die.*

21st.—Doing well, quiet, and rational; has pains and stiffness in limbs; urine quite clear, of natural appearance; a good deal of sudaminal eruption on chest and abdomen, the red has nearly disappeared; some sore throat he had two days ago is much better.

23rd.—Doing well, not the least delirium; pains and stiffness in limbs; pulse 96, very soft; temperature = 38° (100·4). A brushing exocardial friction sound is heard; heart's apex elevated, beats in fourth intercostal space, just below, and to the outside of, the nipple. Blister (2 + 2) to precordia., adde mistr. tr. cinchonæ, ʒi. ad ʒi.

24th.—More delirious; pulse 100, not very weak; tongue too red, moist; urine clear, full-coloured, neutral; marked rheumatic smell; bowels not well open. Pil. hydr. coloc., gr. viij. statim; brandy 10 oz.

26th.—Urine acid, deposits pink lithates copiously; complains of much pain in the back part of forearm, and about the left clavicle; pulse 108; friction sound continues; dulness extends up to the third rib, but there is resonance (of stomach) as high as the fifth; above the third rib good breathing is heard; a good deal of eruption on chest and abdomen still; hands very stiff and painful; tongue dry, and put out with difficulty; is quite rational now.

27th.—Bowels, which had not been acted on by the pills on the 24th, opened by two doses of mist. alba; tongue moister; says he has rheumatism all over him.

28th.—Pulse 108; is rather inclined to wander; not much rheumatism now; loud friction sound heard close under left clavicle, and at inner part of right; takes his brandy and nourishment well; urine clear, of full colour, weakly acid, sp. gr. = 1027.

30th.—Is doing well; very little rheumatism now; friction sound still loud; pulse 93, weakish; much sudaminal eruption still; tongue moist, clear; bowels open with pil. hydr. and mist. alb.

31st.—Temp. = 37·2 (98·96); tr. cinchona ʒi. + pot. iod. gr. ij. + decoct. cinch. ʒi. *t. d.*

1868—Jan. 1st.—Friction sound ceased; o. diet, brandy 4 oz., milk O.i.

4th.—Doing well; apex beat still in fourth intercostal space; urine palish, clear, non-albuminous, sp. gr. 1022.

11th.—Improving daily; urine very pale, sp. gr. = 1006; heart's sounds normal; ferri et. quinæ, citrat. gr. x. + spt. œth. chlor. ℥x. + aq. ʒi. *t. d.*

15th.—Looks pale and cachectic, and emaciated, with a stale, not acid, smell about him; some red spotty eruptions about his chest; much pain between his shoulders; weather mild and soft, thaw and rain having succeeded to frost; adde. mist. strychniæ gr. 1-20, et acidi citrici q. s. ad. ʒi.

23rd.—Improving, but rheumatism still hangs about him.

Feb. 1st.—Is up and about, getting on well, takes food well, but complains of pain at upper abdomen, passing through to the back.

4th.—Had a very bad night with pain at xiphoid, passing through to the back; he can hardly breathe for it, is obliged to lie on his back; he breathes without evident expansion of the ribs, the whole chest rises *en masse*, but there is no play of its individual parts; in the recumbent position I can hear breathing in the fronts, but when I put him up sitting to examine the backs, he complains of severe pain extending from the lower sternum to the back, and he keeps his chest so motionless that there is complete silence; on percussion I find no decided dulness, but the resonance is

rather "woody;" the chest walls being held rigid, do not vibrate as they should normally; heart's sounds normal; the cardiac dulness still occupies the space from the 3rd to the 5th rib; pulse 120, large, open, and very soft; perspires a good deal; urine red, tolerably clear and free, acid; pain has been much relieved by a sinapism; potass. iodid. gr. iij. + ammon., carb. gr. iij. + sod. carb. gr. v. + inf. valerian ℥iss., *quater die.*

5th.—Marked bronchial breathing in right lower back and woody percussion, in left same but less marked with a little moist râle; pain is more about right scapula; lies down at full length; lig. opii. sedat. ℥x., injected subcutaneously.

6th.—Pain greatly relieved; dulness and absence of breathing in left back; in deep inspiration tubular breathing heard; seems quite comfortable.

8th.—Doing well; fairly good resonance in right back; the left is markedly dull at the lower half; good breathing is heard down to the right posterior base, and the vocal fremitus is well felt, even through a linseed meal poultice; in the left back the breathing is distant, weak, and tubular over the lower half; near the spine the air is heard entering more freely, and the tubular sound is louder; vocal fremitus is not felt in the left lower back, at least not through the poultice; in upper third of left back breath sound is normal.

10th.—Much more resonance in lower left back, and much more breathing, the latter is still somewhat tubular, but vesicular begins to predominate, except towards the base, where it gradually gets weaker; heart's sounds normal.

12th.—Is doing well; vesicular breathing, with friction sound (*quasi-crepitant*) heard near left base.

15th.—Tr. Cinchonæ ℥i. was added to his mixture, and he left the hospital in good case about the 20th instant.

In case 2 the rheumatism, which at first was well-marked, receded in great measure as severe delirium set in. This metastasis has appeared to me to be the general occurrence in cases of rheumatic delirium. It is exceptional in my experience that the articular affection persists when the brain becomes notably involved. This delirium was evidently owing to the cause of rheumatism, whatever that may be, and if we believe, as I think we must, that this cause is present in the blood, we can hardly avoid the question—why in so many well-marked instances of rheumatic fever there is no delirium.

The answer must be, I think, that the organ of average vital power persists in its due nutrition, notwithstanding the unhealthy blood which it receives, while the weak organ fails to do so, and consequently falls into disorder. The same thing is observed in many similar conditions. There is a patient now in the wards who has grave degeneration of the kidneys, as shown by albuminuria and low spec. grav. of the urine, which is almost destitute of uric acid; yet she has no delirium, coma, convulsions, or anasarca. In fact, as I have often said to you, in every case you have to consider not only the poison, or *materies morbi*, but also the system on which it acts. It may be out of your power to remove the former, but you may do much to enable the latter to endure the injurious influence better; in fact, to sustain the vital power. You should neither be exclusive humoralists nor solidists, but keep in mind the idea of the separate and distinct life of the tissues, as well as that of their being to a most important extent influenced by the blood. A snake-bite is not cured by means to effect elimination of the poison, but by sustaining the system with alcohol until the depressing effects have passed away. The delirium was rather active, and seemed to require some depressing remedies. I employed at first a combination of opium and colchicum, which acts in some instances very well, but it failed us here. I then had recourse to tartar emetic and cold effusion to the shaven scalp. In the first twenty-four hours he took six and a-half grains of the salt, and subsequently gr. ij. a-day for the next three days. The delirium had then so much subsided that I omitted the antimonial, and replaced it by a small dose of vin ipecac., to maintain some time longer a calmative action on the excited brain. The cold douche was very beneficial, and was rather agreeable to him than otherwise. I used these remedies to reduce the morbid excitement of the hemispheres, which I believe they effected—the antimonial by its direct influence on the nerve-cells of the convolutions, the cold douche by its action on the nerves of the scalp, transmitted centrally. At the same time, however, I did not omit to guard against any possible depression of the heart's power, by directing that the patient should have six oz. of brandy given with milk every twenty-four hours. You need never fear any reproach for inconsistency in thus employing two apparently opposite medications. By guarding your remedies, as in this instance, you will often be able to obtain good effects without incurring the risk of inducing bad ones. That antimony does exert a direct calmative influence on a sthenically excited brain is evident to me, because when administered in full doses its action is often completely confined to the disordered organ, and there is no trace of nausea, diaphoresis, or depression of the circulation. The cold douche to the shaven scalp, I think, is a particularly advisable means in similar cases, because you can adjust its operation so exactly, discontinuing it as soon as it appears to be too depressing. You may often, however, have to continue its use for a somewhat long time—fifteen, twenty, or even thirty minutes at once may not be at all too long. Although in the case before us these decidedly lowering remedies proved positively efficacious, I would not by any means have you think that such are always to be employed. In some instances they might be quite unsuitable, and a full dose of morphia be far more beneficial. In the first case I narrated the patient's condition did not call for the administration of antimony; one full dose of ipecacuanha was sufficient to enable the morphia to take complete effect, but without it you will remember he remained delirious, although he had a second dose of morphia.

Cases are not infrequent, and I have recorded two such in my work, where morphia or opium alone tranquillized acute rheumatic delirium. In fact the morbid action varies much *in quality* in different individuals, and the treatment must be varied accordingly. For patients who show no marked signs of depression opium or its alkaloids are apt to prove too stimulating, and may even increase the disorder. On the other hand, you must remember that depressants are edge tools, and very capable of doing great mischief if employed unseasonably.

The eruption was a very remarkable phenomenon, I have never before seen one so copious in rheumatic fever. For a moment I was led to doubt whether my diagnosis was not erroneous, whether my patient, with a temperature of 104°, and considerable delirium, was not really labouring under typhus. When I saw, however, that the thighs remained quite exempt, I was reassured. The presence and the amount of eruption in acute rheumatism has generally appeared to me to be in relation to the degree of nerve debility. I was, therefore, not surprised to find it copious where the brain was seriously affected. Its production does not, I believe, indicate so much any irritation of the tissue of the skin by the cause of rheumatism, as a loss of tone in the cutaneous vasomotor nerves and capillaries, giving rise to dilatation of vessels and accumulation of blood.

After the delirium had quite subsided, it reappeared again for a few days simultaneously, with a mild attack of pericarditis, and recurrence of rheumatic pain and stiffness in the limbs. In eight or nine days the pericarditis, delirium, and rheumatism had passed away, the only alterations in the treatment being the increase of the brandy to 10 oz., the addition of tr. cinchonæ ℥i. to each dose of the mixture, and the application of a small blister to the precordial region. The hyperæmial eruption soon declined very much, and was succeeded by a pretty copious sudaminal, which did not appear to me to be dependant on sweating.

He went on taking tonics, and during about a fortnight he seemed to be getting quite convalescent, when the rheumatism recurred with another peculiar manifestation.

Pain set in evidently seated in the diaphragm, or in the pleura investing it, and caused for a short time almost serious embarrassment of the respiration. It was relieved by potass iod., and subcutaneous injection of opium; and though it was followed by considerable pleural effusion, this was soon removed, and then convalescence became completely established. In my experience, it is far from common for rheumatism to affect the diaphragm so as to interfere materially with the breathing. Diaphragmatic pleurisy is common enough, but does not seem necessarily to affect the muscular layer. I have notes of one case of right side pleuro-pneumonia, in which after the more acute symptoms had subsided the patient suffered a good many (about ten) attacks of extremely severe pain referred to the epigastrium and the lower parts of chest. He described it as like the pain of cramps, and preventing him from getting his breath. Some of the paroxysms were extremely severe, in one the medical attendant assured me he thought that life was extinct. They lasted about three minutes each. In some of them he had "risus sardonicus." In this instance, as well as in the one you saw, I think the pain was rather a neurosis than of inflammatory origin, although in both cases there were evident inflammatory products. The latter, however, are being continually met with, without any such peculiar and grave nervous disorder, in close proximity to the diaphragm, so that I do not think mere basal pneumonia or diaphragmatic pleurisy sufficient to give rise to the symptom. On the other hand, we can well understand that an affection like muscular rheumatism attacking the diaphragm itself might very seriously interfere with the action of this important muscle. I regret that I omitted to note the abdominal movements at the time the thoracic were suppressed, but there can be little doubt that they were similarly affected. The lower six ribs to which the diaphragm is attached, of course, cannot move without putting that muscle on the stretch to some extent, and we can therefore easily account for the restrained expansive movements. It is worthy of remark that at first the effusion seemed to be about to take place, or to be taking place, most abundantly in the right chest, three days later the left was very notably affected, and the right had become free. This is very like the shifting of rheumatism from one knee-joint to another, and shows, I think, that the nervous system was largely concerned in the matter. Tissue disorders are, as a rule, fixed in the part they first attack, while those which depend on deranged innervation are notoriously the reverse. This probably depends on the much more rapid alteration of the nutrition of nervous tissue.

I have now brought before you examples of cerebral disorder, of spinal-cord disorder, of a peculiar eruption, of pericarditis, and of diaphragmatic rheumatism occurring as anomalies in the course of acute articular rheumatism, but I must refer briefly to a third case for illustrations of two others.

Case 3.—J. J., male, æt. 54, admitted December 5, 1865. Has been laid up five weeks, never suffered in same way before. He was first taken in the middle of the neck, "just as if he had been hit with a great stone;" the left side of the head was first affected, and then the right, and then the disorder extended all over him. His hands and feet are much swelled and inflamed; he can't feed himself or stand; the knees are also swelled and stiff. Pulse 96, compressible, rather bounding. Skin perspiring freely. Tongue rather coated. Heart's sounds normal. Urine has been very red, is more free now. Pot. bicarb. ℥ss.+ potass. iod. gr. i. + vin. colch. ℥ v. + mist. potass citratis ℥iss. 2*dis horis.*

6th.—Perspiration very copious and highly acid; urine barely acid.

7th.—Was very delirious last night, got out of bed; is evidently wandering now, talks of some of his relations working for my firm; answers questions pretty rationally when spoken to. Pulse of fair force, about 90. Heart's sounds normal. Morphiæ muriat. gr. one-third + extr. hyoscy. gr. v.

8th.—Slept a little better, but was very delirious in night. Says he felt very weak this morning. There is but little appearance of rheumatism on hands or feet, or anywhere; less sweating. Pulse 84, soft; head cool; pupils rather large. Takes nourishment well. Morph. muriat. gr. two-third + extr. hyoscy. gr. iij. Pl. mist. *quater die.*

9th.—Had a much better night.

11th.—Last two nights have been very good; he seems to have scarce any rheumatism now, but complains that he has sudden pain of scalding character in both palms, extending down to fingers and up to the wrists, if he uses his hands to take hold of anything; can stand better; bowels open; tongue nearly clean. Tr. cinchon. ℥i. + pot. nitrat. gr. x. + aq. ℥i. *ter die.* Repeat pil.

16th.—Improving; urine alkaline, depositing phosphates; three days ago the urine was clear and acid, pulse large, full, compressible, rather excited. Omitte pil. morph. mist. quinæ, ℥i., *ter die.*

19th.—Getting on fairly, feels weak about ankles. Last night on taking off his boots he found both feet smarting and perspiring; they as well as the lower legs were notably reddened. To-day I find a copious purpuric eruption, the spots being separate above, but coalescing into extensive continuous patches below; the eruption is most marked and considerable on the inner part of right lower leg and the outer of right; both legs are tender in the seat of the eruption, especially the left; his toes feel rather swelled. The purpuric spots and patches are of a dusky dark red. Pulse rather excited, is distinctly weaker than it has been; states that he has always been a healthy man, of temperate habits, has lived well, not been deprived at all of vegetables, takes usually 1 lb. per day. Urine acid clear. Ferri et quinæ citratis, gr. viij. + acidi citrici, gr. x. + aquæ ℥i., *ter die.* Ord. diet, porter, rice pudding.

23rd.—Purpuric eruption very much better.

27th.—Pulse notably weaker than it has been, extremely compressible; legs almost well; back feels weak.

30th.—Some recurrence of rheumatic swelling in left hand; purpura all but gone; strength improved.

Jan. 5, 1866.—Left hospital fairly well.

The delirium in this case was of more asthenic quality than in the other two; it yielded distinctly to moderate doses of morphia. The points for the sake of which I have cited the history are the peculiar dysoesthesiæ which affected his hands as the rheumatism receded, and the purpura of the lower limbs. The former I regard as a peripheral nerve disorder analogous to the central, viz., the delirium, which had just ceased, and doubtless depending on the same cause, which was still, though less actively, in operation. The purpuric eruption seems to me capable of a similar reading, only that I suppose the vasomotor nerves of the skin to have been more affected than the sensory. The first symptom was smarting, a sensory disorder, attended with more or less hyperæmia, probably from relaxation of the cutaneous arteries. In consequence of the defective innervation, I believe the homogeneous membrane of the capillaries became altered and relaxed, so that it allowed the escape of blood into the texture of the cutis. My reasons for ascribing this alteration in the capillaries to failure of nervous power are—1. That instances are on record where sanguineous effusion has taken place from capillary vessels in consequence of some shock to, or irritation of, the nervous system; 2. That purpuric eruption has been seen to follow immediately the use of bromide of potassium (a remedy which often produces drowsiness, and other symptoms of lowered nerve power), in a person who had no hæmorrhagic tendency, and to disappear when the drug was left off. 3. That, as Sir T. Watson states, in facial neuralgia the eye becomes bloodshotten at each attack in some instances; and 4. Because the allied disorder scurvy has been known to be produced by purely mental causes, and to disappear with their removal. It is clear that a deficient supply of vegetables or of potash could not have had anything to do with the occurrence of purpura in this instance. No doubt there are other condi-

tions which give rise to purpura besides impaired nervous influence, but I believe this is one of the most frequent. Lately you remember we had a boy suffering with Bright's disease, in the wards, who was admitted with very marked purpura of the legs. Under the same treatment it disappeared rapidly, but anasarca soon after set in, though it is rather remarkable that it was much more marked in the face and scrotum than in the limbs where the purpura had prevailed, so that it would seem that the conditions determining the two disorders are not quite identical. That the purpura was not a mere sequel of the rheumatism, appears from this, that the latter recurred slightly as the purpura was receding, as also from a case which I have recorded in my work, p. 166, where purpura opened the scene in a case of rheumatic fever. Here also delirium of asthenic quality occurred in very close connection with the purpura, another example of the relation between the cutaneous symptom and deranged innervation. The same is affirmed by the accounts we receive of the very fatal disease termed spotted, or purpuric fever, in which the two most prominent phenomena are delirium or coma, and the hæmorrhage, which is not merely cutaneous, but affects (as simple purpuric may do) sundry of the viscera.

I might have included in this lecture, were it not already too long, some notice of pneumonia and pleurisy occurring in connection with rheumatic fever. But these, as also pericarditis, belong rather to the group of inflammatory complications, and must be reserved for another occasion.

I must not omit to call your attention to another anomalous occurrence in rheumatic fever, viz., its rapidly fatal termination by stupor and coma, while at the same time the temperature ascends to a very high figure, as 109° or 110°. The stupor may or may not be preceded for a short time by delirium, more or less violent. In three autopsies, recorded by Dr. Ringer, the brain and its membranes were found quite healthy; in two of them the pericardium had been inflamed; in all, the lungs were in a fairly healthy state. The rapid invasion of coma and of death by asphyxia, with the simultaneous excessive increase of temperature, are the most notable phenomena. That the temperature should be rising at the time when the respiratory processes are being arrested is remarkable, and, with our present knowledge, somewhat difficult of explanation. We trace however, without difficulty, a relation between the two events, inasmuch as we know that vasomotor paralysis is the chief motor of morbid elevation of temperature, and we find the same kind of disorder affecting the centres of consciousness and of respiration. As far as appears at present, this nervous paralysis must be ranked as functional, not resulting from any demonstrable lesion of the organs concerned.

You will find Dr. Ringer's paper in the *Medical Times and Gazette*, October 5th, 1867. Schönlein has recorded a somewhat similar instance, which I have cited in my Lumleian Lectures.

ON THE TREATMENT OF DISEASES OF THE SKIN.

By J. L. MILTON,

SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

(Continued from page 455.)

CHAPTER III.—TINEÆ.

Definition.—Dry scurfy, reddened, or pale and shining patches, accompanied, when on the scalp, by shedding, twisting, loosening, and falling of the hair, and in some cases secretion of scales.

Divisions.—1. T. areata (alopecia areata or area). Sudden falling of the hairs from small patches of the scalp, often nearly circular in form, leaving a white, polished, and often wasted state of the skin. After the epidermis has once been thrown off there seems to be scarcely any reproduction of it. General alopecia, a simple thinning and falling of the hair, may be classed as a mild chronic variety of this. 2. T. decalvans. An aggravated state of the former, the whole head of hair being swept off in a very short time, only a solitary patch or two, or hair or two, being left. 3. T. tonsurans, in which patches of the hair, generally somewhat circular in form, are cut down to stumps. 4. T. circinata or ringworm. An eruption of red, nearly circular, erythematous patches or groups of very small red papulæ, generally seated on the head, neck or arm. 5. T. favosa. Formation of red, slightly tender patches, generally on the scalp, which gradually become covered with small, yellow, adhesive tenacious crusts, marked by a peculiar mouse-like smell, accompanied by loosening of the hair, and wasting and blackening of the roots. May also attack the face, thigh, nail, &c. Hardy gives as the characteristic signs of favus—1. The mycelium, an assemblage of filaments, sometimes simple, sometimes branched. 2. Tubes, simple or celled, isolated or adhering to one another; some empty, others containing spores. 3. White granules, oval or rounded, sometimes irregular, of variable volume. These are supposed to be the spores or organs of reproduction of a parasite of vegetable nature, the achorion Schönleinii. With a magnifying power of two to three hundred diameters, numerous spores may be seen, and sometimes tubular filaments may be detected in these parts. The Burmese ringworm seems to be clearly a local form of eczema.[1]

As those who contend for the parasitic nature of tineæ found their treatment upon the view that the parasite is vegetable, and as those who deny the vegetable nature of the parasitic structures uphold a very different kind of treatment, it becomes absolutely necessary to examine the contending views, however briefly.

If I understand aright the view put forward by the former, it amounts to this, that the parasitic growths on the skin are as truly vegetable in their nature as the mould on an orange or melon, because we can distinguish the presence of cellulose externally, and can see internally the primordial utricle coloured by iodine, and because we find in the secretions of these diseases the tubed mycelial thread, and a fructification unrepresented in animal structures. Ether, chloroform, and spirit of wine, do not affect these parasites, while they make epithelial tissues transparent, and dissolve all fatty matters. The parasites mostly grow in places to which the air has free access, exceptions to this rule admitting of doubt; they grow too, when removed from the influence of blood and living tissue, a separation which is fatal to animal life. A piece of favous matter, if fittingly nursed and tended, will take root and flourish; the nuclear element will assume the sporular form, and the sporules will gain in size, join, bud, and bring forth mycelium, while the very structure on which they are seated is decaying. Dr. Fox showed his friends a beautiful specimen of the tricophyton tonsurans, which had blossomed in a most delicious manner, while the fibres of the hair on which it grew had degenerated, and their place had been supplied with delicate tufts of crystalline fatty matter.

Dr. Fox says,[2] "take away the damaged hairs, &c., of tinea, and nothing diagnostic of the ravages of the parasite remains. *Per contra*, remove all the eruptive and the parasitic remains in its integrity: the necessaries remain, but the accidentals are absent. The presence of the fungus increases the local irritation. Now, if the fungi be different, there must be different soils, and the treatment be different in kind. If the fungi be identical in nature, then the treatment is a matter of degree only; if fungi be different, then ought they to be so many indices to states of economy, states which in time will be fully interpreted."

Accordingly, to cure the disease and destroy the fungus,

1 See Journal of Cutaneous Medicine. Vol 1., p. 379. This is also Mr. Wilson's opinion.

2 The Nature of the so-called Parasites of the Skin. By W. Tilbury Fox, M.D.

you must root out every diseased hair, by gentle means if you can, but pull it out. There can be no doubt that such views are now very widely accepted. Dr. McCall Anderson is unreservedly in favour of this system. "Considering as I do," he says,[1] "that its essence consists in the presence of a parasite, I hold that its destruction is the *sine qua non* of the treatment." He, therefore, has every hair removed with broad pointed forceps, and clears three or four square inches of scalp at a sitting. Dr. Hillier says that tinea tonsurans and tinea favosa cannot exist without their respective fungi.[2] The diseases known as tinea, he says, essentially depend on the presence of microscopic fungi. M. Bazin, among others, adopt much the same view.

To all this, Mr. Wilson replies that the parasitic bodies are produced by "granular degeneration" of normal tissues, and he refers for corroboration to such instances as the development of mucus and pus. He says that upwards of twenty years ago, he came, after a very careful examination of the subject, to the conclusion that the pathological elements resulted from aberrant cell-growth, consisting in the growth and proliferation of the primary granules of which epidermic-cells and hair-cells are normally constituted; that this growth and proliferation had the effect of arresting the granules at their embryonic stage, and in the performance of their embryonic functions, and as a consequence that the cell-tissue (epidermis and hair), composed of these embryonic granules and imperfectly elaborated cells, became, upon dessication by the air, dry, spongy, and brittle; that in trichosis this change alone took place in the hair, whereas, in favus, the granules composing the yellow disks around the mouths of the follicles, pass through a pustular stage, the consequence of a higher degree of inflammation, and in their pustular condition acquire their peculiar yellow colour. This morbid alteration he considered then, and considers now, to be granular degeneration.

As regards the mode of increase and production, Mr. Wilson contends that "the granules are nucleated, separate or in groups, or adherent in moniliform strings of two to four or five in length. The greater number of the granules are uninuclear; some, however, are binuclear or trinuclear. The binuclear granule is in process of separation; the original nucleus has split into two, each moiety has become a separate nucleus; the space between them has increased; a septum has arisen in the interval, and the cell has become oblong—an oblong cell with two nuclei, or rather with two independent but adherent cells, cells that may subsequently divide and become separate cavities. This is the mode of all proliferation." At an early stage, and while in near contact with the vital tissues, the tendency is to the formation of granules, but "removed from the source of nutrition proliferation weakens, the divided cells remain adherent, and either retain their globular and independent shape and give rise to moniliform filaments, or they grow in length at the expense of their contents, and form cylindrical and transparent filaments divided by septa, each internodial segment representing a single original globular granule or cell." In the latter case they lapse "into an irregular and filamentary proliferation, giving rise to an inferior form of organization, neither so complete nor so permanent, and which converts the higher animal organization into a lower and phytiform organization—an animal tissue into one which might be likened to a vegetable tissue."

These quotations, then, give us as the sources of the so-called fungus elements, the normal tissues (epidermic granules), the nature of the disease which is here looked upon pathologically as a granular degeneration; the mode of increase by the division of the nuclei of the cells, and the secondary division of the cell itself; the formation of the so-called mycelium by the division of the nuclei, and the breaking up of the binucleated cells into separate unities. These stages are best seen in favus. The granules are globular, uninucleated, bi and tri-nucleated; the mycelial forms are moniliform and opaque, cylindrical and transparent, with a branched and ramified filament. "In the case of the trinuclear cell, a bifurcation is effected, and the proliferation of each part of the tissue cell lays the foundation of a branched and phytiform growth." The peculiarity of favous "is due to a pustular complication;" the layer of the favus mass, next the basement membrane of the derma, is made up of pus globules; "these pus globules contain from four to seven or eight well-formed nuclei; and these nuclei on their escape from the cell-membrane of the pus-globule, become the nucleated granules which are the chief constituent of the pathological product." The moniliform thread is produced by the coalescence of these escaped nuclei. We have then to notice the view that in favus the phytiform elements are derived from the nuclei of pus-cells. Mr. Wilson interprets the term granular degeneration by "the idea of an arrest of development of the cell-tissue of the epidermis at its embryonic stage, and the production of a tissue constructed of crude and imperfect materials, which represent an earlier period of all generation than that which nature intended, and which, in consequence, is truly in a state of degeneration from the perfect type."

THE LOCAL TREATMENT OF HAY-FEVER.

By JAMES YEARSLEY, M.D.

THERE are no facts in the history of our profession so satisfactory as those which arise out of, and become verified in, the course of practice whilst treating maladies different to those for which the treatment is intended; such, for instance, is the result of using instruments I have adopted for many years in cases of ozena, obstructions and defluxions of the nose, relaxation, prolapsus, and ulcerations of the membrane. In the course of practice in the local treatment of these maladies by instrumentation, I have recently met with cases in the season of hay-fever, and I believe that distressing malady may now be added to the armamentarium of my specialty, for patients have expressed their surprise and pleasure at finding the great amelioration, ending sometimes in cure, of their troublesome malady from the application of the instruments I had been using.

As my object in writing on this occasion is more to beg the question among your readers and to test for themselves the value of the instruments, than to prove their success in hay-fever (whilst during the season cases abound), I will merely briefly relate an instance in point.

Two years ago Mrs. —— had suffered very much from obstruction and defluxion of the nose, with great irritation extending to the throat, and sometimes to the eyes. Deafness had also supervened, and it was chiefly on this latter account, I believe, she came to consult me, but the malady was clearly enough associated with hay-fever. Her general health suffered considerably from the local symptoms. The treatment consisted in using the elastic tube and bottle, by means of which injections of water only were introduced, sluicing, as it were, the whole surface of the convolutions of the nose and pharynx. The result was most successful. Remembering her case, I recently addressed a few lines asking if she were still a sufferer from hay-fever? In the course of her reply she says, "Some months ago Mr. S. (whose reputation as a skilful operator is doubtless known to you) visited me several times for the purpose of inserting something into my eye some way down my nose, as he thought from my symptoms the lachrymal duct was stopped. I certainly have been much freer from hay-fever since then, though my old enemy has by no means left me, and added to it, I am more or less suffering always from irritation in the throat, which often prevents my sleeping."

I certainly do not expect that the mere passage of a bougie through the lachrymal duct into the nose will relieve hay-fever, but I do contend for the passage of bougies over the surface of the mucous membrane along the floor of the nasal passages, and on the same principle that we cure gleet in cases of urethral irritation, relaxation, and dis-

charge, by the use of bougies. Add to the employment of instruments the use of appropriate injections, and we shall do more than mere medical treatment can do for the removal of hay-fever.

A lady consulted me for deafness. It was soon made evident that she laboured under obstruction of the Eustachian passages, and, in the course of conversation, she incidentally mentioned that she was the subject of hay-fever, and that on this occasion her deafness was no doubt aggravated by it. Catheterism afforded relief of the deafness, and, to her surprise, the attack of hay-fever was so much ameliorated, that I could not but consider it as the result of the passage of the catheter; consequently, I supplied my patient with a nasal probe, which she afterwards used night and morning, and the hay-fever, which had been chiefly limited to the nasal passages, has never recurred. In anticipation of the season when she may be subjected to the malady, she will use the probe with confidence, that it will be her safeguard. Cases of hay-fever, or maladies akin to it, far more marked, have subsequently come under my notice, and have yielded to local treatment so rapidly, that I have gone into the question with more energy and consideration, firmly believing that an *hiatus* in the therapeutics of hay-fever has been overlooked. Two very clever *brochures* have recently appeared by two experienced physicians—Dr. Abbotts Smith, and Dr. Pirrie, on the subject of hay-fever, but I fail to discover in the pages of their philosophical disquisitions, one word of the local treatment upon which I am myself disposed to rely as the most successful panacea for the malady.

The instrument I use, beyond the naso-guttural tube and bottle, and the nasal probe, both of which are figured in my work on "Throat Ailments," is a silver tube, minutely perforated at its extremity, and curved so as to enable the operator, or the patient, to introduce it over the tongue, and under the soft palate, so that when thus introduced, the contents of the india-rubber bottle at the end of the silver tube filled with the injection may be diffused in the form of spray over the extensive surface of mucous membrane which covers the convolutions of the nares and the upper pharynx, and, indeed, to trickle down the pharynx and larynx generally. The instrument I have denominated "spray diffuser," in cases of ozena, hay-fever, obstructions and defluxions of the mucous membrane, of the nares and upper pharynx, is manufactured by Weiss and Co., Strand.

OCCLUSION OF VAGINA.

By JAMES MARTIN, F.R.C.S.I., L.K.Q.C.P.I.

KATE F——, æt. 17, factory operative. Has been in bad health for the last year, complaining of headaches, flushings, and lumbar pains. Had never menstruated.

March 23rd, 1868.—My assistant was called to her in the middle of the night, as she was suffering from retention of urine.

He relieved her by the introduction of a catheter, but informed me next morning that there was a tumour protruding from the vagina, which had produced the retention by pressure on the urethra.

On visiting her, I found a fluctuating tumour protruding between the labiæ and compressing the urethra against the pubis.

Examination showed this, to be a membrane, completely occluding the vagina, and pressed on behind, by retained fluid; strange to say, the hymen was perfect, and I could pass my finger between it and the occluding membrane.

This latter was tough and fibrous. I divided it through its length, by means of a bistoury, and gave vent to about three pints of dark grumous matter, evidently the pent up menstrual discharge of many periods. It was expelled with considerable force, the urine gushing from the urethra at the same time.

She experienced immediate relief, and after a few days returned to work, enjoying better health than she had experienced for a long time. The improvement in the character of the face was most marked, five weeks have now elapsed, and she has menstruated without difficulty. No means were taken to dilate the incised wound, yet it remains perfectly free and open.

A point of interest in this case is, that it was not one of imperforate hymen, but the occlusion was caused by a perfectly distinct membrane.

THREE CASES OF CHOREA SUCCESSFULLY TREATED.

Miss C——, æt. 13, dark-hair, marked struma in the family, came under my care in 1861, with bad chorea; when sitting, both legs and arms were spasmodically jerked and contorted in a painful manner, but when walking, the lower extremities performed their functions steadily. The arms, however, jerked incessantly, and she had to give up attempting to play on the piano, so little control had she over their movements; nine years ago she passed lumbrici from the bowels. Pulse 90 and feeble.

I commenced the treatment by a full dose of castor oil and turpentine, which acted powerfully, but no worms were discharged.

I followed up during the next three weeks, by giving half a grain of valeriat. zinc and one grain of valeriat. quinine three times a day, and as the bowels were confined, ordered an electuary of carbonate of iron and super-tartrate of potash, to be taken at night, as required. I also ordered tepid douche-baths, moderate exercise, and fresh air, with nutritious diet.

At the end of three weeks, she was much improved, could sit quiet, without any spasm of the lower extremities, and exercised such control over the arms as to enable her to play short tunes on the piano. I now changed the medicines, giving up the valerianates, and substituted citrate of iron and strychnine, under which she rapidly recovered. A short time at the sea-side, cod-liver oil, and general hygiene, perfected the cure; the menstrual secretion set in after eight or ten months, and she is now a strong healthy young woman.

Catherine Hayden, æt. 13, came under my care in March, 1863. Both parents died of phthisis. Countenance pale, grey eyes, light-coloured hair, and slight figure. This was the worst case of chorea I ever saw, and only that her eye showed that she was conscious, I would have said that she was in violent convulsions, such were the contortions and twistings of the entire body, the muscles of the face being the only voluntary ones not affected.

I adopted precisely the same hygienic and therapeutic course as in the last case, and with equal success. The catamenia appeared during the convalescence, and before six months she was able to work in a factory, which she has continued doing ever since.

She is now a grown girl, and though of delicate frame, in excellent health.

Miss C., æt. 15, dark hair, but strumous by father and mother, was brought to me labouring under severe chorea. Could not sit still a moment; jactitation incessant, and constant rubbing of the chin against the breast; has menstruated regularly during the past year; looked fat, but flabby; pulse 80, tongue clean.

I first cleared out the prima vice with pulv. jalap comp., and then pursued the same treatment as in the other two cases, with perfect success.

CASE OF HERPES ZOSTER.

Miss B., æt. 18 years, dark hair, florid complexion, full red lips, had an attack last winter (*i.e.*, '66-67) of gouty rheumatism in the arms and wrists, which lasted nearly two months, during which time she suffered greatly from urticaria. I treated her with alkalies and quinine; but on getting rid of the rheumatic symptoms she did not recover full health, their being a strong tendency to hysteria and neuralgic pains, with, at the same time, great tenderness over the fourth and fifth dorsal vertebra. In November last I was called to see her in an aggravated attack of

hysteria, which I combatted in the usual way, with æther camphor and sal volatile. The next day she had an eruption of shingles, which gradually spread all round the body from one side of the spot of spinal tenderness until it reached the other.

For eight days they remained exceedingly painful. All the hysteric symptoms, such as crying fits, palpitations, globus, &c., being much increased. During this period the urine, before limpid and plentiful, became scant and high-coloured, and threw down large deposits of lithates and phosphates. I treated her with large doses of citrate of potass and small doses of vin colchici combined, supporting her with beef-tea and claret.

On the eighth day the herpetic eruption began to dry up, and the hysteric symptoms to subside. As soon as the renal secretions became clear and plentiful, I followed up the treatment with valerianate of zinc and quinine, and carbonate of lithia.

Her convalescence has been perfect, and the tenderness of the spine has quite passed away.

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

OPERATIONS PERFORMED ON THE 26TH MAY

By Mr. CROLY.

OPERATION FOR ENORMOUS PROLAPSUS RECTI.

Case 1.—Enormous prolapsus recti of eight years' duration in a woman forty years of age, unmarried, residing in the county of Tipperary.

The patient had been operated on previously by the local application of nitric acid, which, for a time, afforded some relief. She was recommended by her medical attendant to Mr. Croly for further operation. The prolapsus was of unusual size, and caused much distress to the patient. The mucous membrane was congested and thrown into large folds.

The patient having been placed on her left side on the operation table, was told to force down the bowel :—

Mr. Croly then proceeded as follows :—A fold of the mucous membrane of the bowel, close to the anus, was raised with a forceps (in the long axis), and firmly tied with a strong hemp ligature. This was done at four opposite points. The patient did not complain of pain. The prolapsed bowel was then reduced (having been previously oiled), and a piece of ice was introduced into the rectum ; a compress and T bandage were applied. The patient was removed to bed. She then complained of pain, and a full opiate was accordingly administered.

Mr. Croly gave some practical instruction to the pupils on this case, and detailed the various causes which may produce the affection, and the several methods of treatment recommended for obstinate cases of prolapsus recti, particularly observing that in ligaturing or otherwise treating the mucous surface of the bowel it is important to remember that the part of the prolapse near the anus is the portion to be operated on, and remarked on the caution necessary to be observed in not removing too large a portion of the mucous membrane, lest constriction of the gut might eventuate, and said he reserved for further operative treatment (if necessary) Hey's operation, adopted by Dupuytren, which consists in removing radiated portions of integument close to the anus.

REMOVAL OF PORTION OF THE LOWER LIP FOR EPITHELIOMA.

Case 2.—Epithelial cancer involving the right side of the lower lip, in a man aged 50 years, a resident in the Queen's County. The disease, which commenced about two years ago, was attributed to smoking with a short clay pipe. There was no glandular contamination or cancerous cachexia.

The patient was seated in an arm-chair, and the facial arteries having been compressed by an assistant as they pass over the jaw, Mr. Croly commenced by detaching freely the mucous membrane connecting the lip to the jaw, and then transfixed the lip with a long straight bistoury beneath the diseased portion, cutting upwards through the red margin another incision from below upwards, enabled him to remove a V shaped portion of the lip. Three hair-lip pins were introduced, and silk ligature formed the twisted suture. Narrow strips of adhesive plaster were next applied between the sutures, to give additional support.

OPERATION FOR VESICO-VAGINAL FISTULA.

Case 3.—Operation for vesico-vaginal fistula in a young woman from the County of Fermanagh.

The fistula was at the left side, and about as large as a sixpence, with a well-defined lower margin. The upper portion was callous, and there were adhesions above it.

The patient was placed on a prone position, leaning over a table of convenient height. The duck-bill speculum was introduced into the vagina, and held well up by an assistant. As the mucous membrane of the bladder protruded through the fistula, Simpson's sound was passed through the urethra to keep it down.

Mr. Croly commenced by making raw the lower margin of the orifice, and then removed the hardened upper portion. He next introduced six fine iron-wire sutures. A catheter was passed into the bladder ; the patient was placed in bed in the prone position, and a small dose of opium was ordered to be administered every second hour to prevent spasms of the bladder.

We hope to give further details of these cases.

NEWCASTLE LUNATIC ASYLUM.

Under the care of Dr. HUGH GRAINGER STEWART.

THE Pauper Lunatic Asylum of the Borough of Newcastle-on-Tyne, under the management of the present medical superintendent (Dr. H. G. Stewart), is in as good a state of efficiency as is practicable in the present asylum at Bensham, but it is believed that by the end of the year the new buildings will be ready to receive the patients, who will then be much more suitably accommodated. We extract some interesting cases from the last annual report of the superintendent :—

Many cases of great interest have been received during the year. M. E. B., aged 20, married, suffering from acute mania after the birth of her first child, was received almost in a dying state. For months she lay, apparently moribund, without movement, or manifesting a spark of intelligence; several medical men who saw her thought the case absolutely hopeless. By means, however, of very careful nursing and medical treatment, she gradually regained strength and reason, and was eventually discharged recovered. Such a case illustrates well the great value of asylum treatment, where good nursing, and early observation and relief of symptoms, are essential to success. For some time after this patient's return to her friends, she continued well, but soon began to decline in bodily health, and died several months after her discharge from the asylum.

The cases of T. A., a male, aged 53, married, and E. H., a female, aged 40, both of suicidal melancholy, exhibit the value of a long-continued use of the stomach-pump, as a means of introducing a sufficient quantity of suitable food into the system, when it is urgently required, and cannot otherwise be given. At various times, both of these patients have, for months together, been entirely dependent for their alimentation on the use of this intrument. Both are now much better. The man will, it is feared, never entirely regain his reason; but the female is in a fair way towards recovery.

J. B., a male, married, aged 64, was admitted, with his throat severely cut, the windpipe and gullet entirely severed, but, by a miracle, the large arteries of the neck

uninjured. The food he attempted to swallow passed out by the wound in his throat, and irritated the air-passages, bringing on severe fits of coughing. He complained of great thirst, and was very feverish. He was very anxious to die, and, in fact again attempted to put an end to himself by tearing the wound open with his fingers. Recourse was had to the stomach-pump in this case, but great difficulty was experienced in passing the tube, as it was almost impossible to hit on the continuation of the gullet beyond the wound, partly owing to its being much lacerated and inflamed, and also to the resistance the patient offered. This treatment was persevered with, and a good meal was administered twice a day for a month. The patient gradually became most anxious to live, and rendered all the assistance he could to the operation which saved him. The wound healed, and, by placing his head in a certain, attitude, he learned to swallow without any of the food passing into the air-passages. He was discharged recovered. The history of this case illustrates forcibly the value of proper and sufficient nourishment. The moment his system received a sufficient amount of good food and stimulant, an amendment took place in the mental health of this patient—from desiring most ardently to die, he began to wish to live, and promoted that object by every means in his power.

Another individual, who attempted suicide by cutting his throat, was received about the same time; the wound was not so severe, and the patient is greatly improved, but his mind has suffered a severe shock, from which it is not likely it will entirely recover.

A potent cause of disease of all kinds is that condition of semi-starvation in which many of the poorer classes of our large towns must live. On the brain, this continued want of sufficient nutrition has the most disastrous effect. Some of the most violent cases that have come under treatment this year have been directly traced to long-continued deprivation of those substances which are necessary to the maintenance of the body in a healthy state. The treatment of such cases is clearly indicated by the known cause of the malady, and, if the disease has not existed too long, cure may be looked on as almost certain. In some cases the brain, during the acute stage, receives such injury that it never again performs its functions properly, and the individual becomes, during the rest of his life, a burden to his friends or the public. Taken in time, such cases need never enter an asylum; were sufficient relief administered when it ought to be, the patient would be saved from his madness, and the public the cost of his care.

E. F., a male, single, aged 30, the practice of whose art necessitated his having decent rooms and furniture for the reception of his patrons. To keep up appearances, he had long to go on a pinched diet, sometimes actually starving. This continued for months, gradually deteriorating both his body and mind. At last the inevitable crash came in an attack of acute mania. The cadaverous countenance, sunken cheeks and face, pinched by famine, were a strange contrast to the bright eye and hopeful voice which told of wealth and prosperity awaiting him, and boasted of his activity, skill, and success. The cause had been in operation for a considerable period, and the treatment had to be continued for some time before its good effects were manifested, but recovery eventually took place, and the patient was discharged.

CHOICE OF A PRISON.—The following dialogue is stated to have taken place between a visiting magistrate at one of the city gaols and a juvenile offender serving out his three months:—"How old are you?—Please, sir, I'm 13. How often have you been in gaol?—Please, sir, eight times. Have you ever been in Reading gaol?—Please, sir, once. Have you ever been in Westminster gaol?—Please, sir, once. How often have you been here?—Please, sir, six times. Why do you come here so often?—Please, sir, becos at Westminster the turnkeys knocks yer about with their keys. How do you contrive to get sent here?—Please, sir, I allus prigs in Holborn now.—*Pall-Mall Gazette.*

WEDNESDAY, JUNE 3, 1868.

STATE MEDICINE.

THIS subject seems likely to attract considerably more public attention than it has done hitherto. Our readers will remember that the Social Science Association appointed a committee to confer with a committee of the British Medical Association. The co-operation of these committees has resulted in a memorial setting forth at great length the manner in which, in the opinion of the joint-committee, it is possible for the legislature to promote a better administration of the laws on Medico-legal investigations, on the Public Health, on Registration, and on other subjects falling within the sphere of State Medicine.

The next part of the proceedings we have to chronicle is that a deputation has waited upon three of the ministers to point out the changes thought necessary in the laws relating to these matters.

The deputation was a very influential one, including the names of Sir THOMAS WATSON, Dr. BURROWS, Dr. ACLAND, of Oxford; Dr. RUMSEY, of Cheltenham; Dr. SYMONDS, of Bristol; Dr. GAIRDNER, of Glasgow; and others who take a deep interest in State Medicine. But for the short notice that could be given others would also have attended. The deputation urged upon the ministers the imperfections of the laws on registration, pointing out that a certificate of death is not sufficient evidence at the Bank of England, and suggesting that many murders escape detection through the inefficiency of the registration system.

We have so recently commented upon the late attempted frauds by means of certificates of death, that we may pass at once to the other points.

It was desired that a plan should be organized for the registration of disease. There can be no doubt at all, as we have before had occasion to urge, that a registration of prevailing diseases would be an invaluable supplement to that of the causes of death. Indeed, it would be difficult to suggest any more important vital statistics than these; but the difficulties in the way of a complete plan seem to be almost insuperable. It would be impossible to obtain a return of every case he had attended from every medical man in any district. Yet, anything short of this would be incomplete. Still, most important information would be obtained, if a return could be procured from all public institutions of the diseases weekly brought under notice. Again, the Poor-law system affords abundant opportunity of collecting such data; but, as we said when this was lately proposed, the Poor-law doctor is already overburdened with the amount of book-keeping he is expected to perform, and any addition to his duty might fail to be

accompanied by extra pay. Again, we believe that some medical officers of health have made the attempt, but being compelled to rely upon the voluntary assistance of their brethren, and having no funds to remunerate them, the plan fell through. What we appear to need seems to be a large increase in the number of the Medical Officers of Health, and to these posts men should be appointed who are not distracted by the cares of private practice. They should not only be well paid, but should have funds placed at their disposal to enable them to conduct investigations and inquiries, for which the aid of their professional brethren is needed. We fear, however, that such a scheme involves too much for the tax-paying digestion.

Turning now to the general condition of sanitary regulations and State medicine, what do we find? A hopeless state of confusion. It was even admitted by the Ministers at the deputation that the present complicated system is most embarrassing, and the propriety of consolidating the sanitary laws and uniting the Public Medical Departments was said by the Duke of MARLBOROUGH to be under the consideration of the Cabinet. This is certainly good news. It is highly satisfactory that any branch of State medicine should occupy the attention of Government, and as any consideration given to the subject cannot fail to bring out the necessity of change, it would seem not improbable that the Royal Commission for inquiry asked for by the Deputation may in time be granted.

We have not, to be sure, the utmost faith in the results of Royal Commissions, but as it would be manifestly absurd to add to the existing confusion by more patchwork of legislation without sufficient data, and as there is time for such an operation, we certainly think that a case has been made out for official inquiry.

Private effort has done much, and public inquiry may certainly do more, provided that inquiry be intrusted to independent men interested in the questions, and not relegated to mere officials, or to gentlemen who are already committed to the advocacy of any particular scheme.

MASTERS, DOCTORS, AND NURSES OF ENGLISH WORKHOUSES.

ANY one with a taste for unseemly personal squabbles may gratify it at a moderate cost, by a perusal of the papers printed by order of the House of Commons, in reference to the appointment of Mr. GEORGE CATCH to a new workhouse mastership. We are not about to rake up the most offensive details. We only barely allude to the charges and counter-charges made—the giving the lie direct—the heaping of insult upon insult, which exemplify the disgraceful manner in which our Poor-law system works. Whatever may be the faults of Mr. CATCH, and we by no means feel inclined to extenuate them, the system is most to blame which places the medical officer in a position in which his orders may be countermanded, his directions neglected, and his reputation imperilled by the obstinacy or ignorance of an unscrupulous or uneducated person dressed in the little brief authority of a workhouse master. Is it not intolerable that a professional man should be thus treated. As testified on oath in this case, nurses may be told to disobey the doctor, stimulants may be refused although ordered; paupers, with orders for admission, may be kept outside the door all night; the female wards may be intruded upon at night by a man who has no business there; a nurse, sent to get hot water, may be bullied; the doctor may be warned that he will be "taken down a peg or two," and other annoyances, vexations and insults, may go on for months to gratify an ill-tempered, or half-mad master. And what is to be gained by this system of keeping the medical officer in subjection? Nothing but mismanagement and the many iniquities that have recently been exposed.

How would such a plan work in our hospitals, supported by voluntary contributions? Why, the whole medical and nursing staff would resign, and they would be quite right, too!

If a despotism is ever to be exercised it should be by medical men in the sick wards. Here nurses and every other official should feel that medical authority is supreme, and that every one's convenience is to be put aside upon the order of the doctor. This is done in our hospitals. It is done in the homes of the wealthy and the middle classes. It is done in the cottages of the independent poor. But in our workhouses we set up vulgar ignorance, in the persons of the masters, and expect they will not abuse the power we give them. The whole system is bad, and we wonder the medical inspectors have not protested against it.

It is of little importance that the individual whose conduct has been officially inquired into was condemned, after a patient inquiry by Mr. FARNALL; that his temper was found unbearable by all the other officials; that he neglected to supply a pauper with crutches for three months; refused special watchers for lunatics; transferred sick paupers to the infirmary without medical orders, or in opposition to them, or incarcerated a weak-minded female in a small, strong room all night, without light or bedding. These and other things are pronounced proved by the inspector, but are probably no rarities in workhouse management; and that they are but venial sins in the eye of the Poor-law Board is shown by the permission granted to the delinquent to occupy a similar situation in another workhouse. For the sake of the paupers we hope the inquiry that has been made, may have taught him a little more prudence and humanity, and that he will devote his energy in future to helping the medical officer in his arduous duties, instead of thwarting him. If he has not learned a little humility, and is not prepared to give up the idea of taking down his superior "a peg or two," then alas for the patients, and alas for the doctors and nurses. It is to be hoped, however, that these latter, on the first occasion of such offences as have been officially condemned, will put away the fear of Bumbledom from before their eyes, and report the facts—without comment, to show they have no animus—to the enlightened Board that thinks so little of the pauper's peace, or the doctor's responsibilities and trials, as to perpetuate a system by which the patients are deprived of what the country pays for, and the doctor is reduced to a state of helplessness or dependance upon ignorant and vulgar persons who delight in the tyranny of their office.

If the Poor-law Board really thinks the existing plan so excellent, let them try it in their own homes. Let one of them encourage his cook, butler, or footman to frustrate his physician's plans, and see what would be the result. Then let him remember that pauper patients feel, and Poor-law doctors are also human.

OUR attention has been called to the fact that the granular preparations of citrate of iron with strychnine, and also the citrate of quinine with iron and strychnine, recently noticed in our columns, were introduced to the medical profession by Messrs. W. Twinberrow and Son.

PRIESTS AND PHYSICIANS.

THE third series of "the Church and the World" has been published not many days ago; and contains, among other exciting essays, one on the above subject by Dr. ALFRED MEADOWS, a well-known metropolitan member of our profession. To the uninitiated, it may be advisable to say a few words explanatory of the meaning of the phrase, "the Church and the World" in connection with books of this kind. Some years ago the "religious world" (as it is called) was startled by the publication of a now notorious volume entitled, "Essays and Reviews;" to which numerous "replies" were made in the same fashion. Apart from all religious considerations, its publication may be said to have inaugurated a new style of literary work :—A system whereby, instead of one man writing a book, and standing or falling by his views and statements, several join together in publishing a work with one general tendency, with this important *caveat* however, that each contributor is held responsible for his own contribution *only*, and for some essays with fictitious signatures, no one is to be held responsible at all. "The Church and the World" is then the essay department of the Ritualistic, or ultra-high church party in England; and in this light Dr. MEADOWS comes before the public and ventilates his views on "Priests and Physicians." After some preliminary remarks, he states his object as follows :—

"I am anxious above all things to make it understood that my aim is essentially of a practical character. I desire, if possible, to extend the influence of the Priest and the Physician in their respective spheres of action, believing, as I do, that the usefulness of both would be enhanced by a closer communion between the sacred Order and the godlike Profession. The questions then which I propose to consider are :—Whether the study of medicine can be made in any degree advantageous to the Parish Priest? Whether any good would result from a more intimate association of Priests with Physicians? And, whether the study of the science of Theology, if I may so term it, might not with advantage be made, at least optionally, to form a part of the ordinary curriculum of study required for the proper education of the physician?"

A considerable part of the essay is occupied with fencing in the rather dangerous ground on which the essayist treads. To advocate priestly dabbling in physic, and yet to prevent the priest being a quack; and to advocate close operative union between the physician and the priest, and yet to prevent the physician doing the amateur parson, are questions so difficult as to render them all but impracticable for good results in this country. If theology be a science requiring learning and long study, no mere tyro should take on him to meddle therewith, even though he be a physician; and as the science and practice of medicine exist among us now, the idea that the priest could do the physician also, is out of the question. In the working of missions among the heathen the matter is different; but even there experience has shown, that if the priest desire to practice physic, he should learn to do so in the ordinary way, and qualify himself by education and examination, like any other man.

In the essay above referred to, Dr. MEADOWS gives a short history of the ancient connection existing between the clerical and medical professions, or profession, to speak more accurately. In alluding, however, to the prohibition of the study of medicine by ecclesiastics, issued by Pope INNOCENT II. in the twelfth century, he has omitted to state that this enactment was almost a dead letter in England at all times. Dean HOOK, in his "Lives of the Archbishops of Canterbury," has clearly shown that in mediæval times the ecclesiastical establishment in England was made use of by the State to pay its most important functionaries. All, or nearly all, useful public men took holy orders at sometime or other of their lives. When the King wished to remunerate a great lawyer, he gave him Church preferment; he did the same for an ambassador, and for his physicians. MUNK'S "Roll of the Royal College of Physicians of London," shows that the earlier members of that body were beneficed clergy, and when we consider the present use of Woburn Abbey and other ecclesiastical foundations, of which the State may yet resume the control, we must not forget that, down to the time of the general dissolution of the religious houses in these countries, one important function discharged by them was the care of the sick poor, by monks trained as physicians; so that when HENRY VIII. laid hands on the property of the Abbeys and Monastries, the entire extent of the land—says Lord MACAULAY—was, with one or two exceptions, deprived of all medical and charitable relief for the sick and the poor. Long after the priests were wholly forbidden to practice *Surgery* (because it involved the shedding of blood), they were allowed to cure the sick, when it was not done for gain; in other words, when it did not withdraw them from clerical work.

On page 506, referring to the statute of the London College of Physicians, prohibiting Clerks in Holy Orders from being admitted to examination for medical license, Dr. MEADOWS says—"Thus was completed the severance between the Clerical Order and the Medical Profession."

This is incorrect. Our profession as a body has never made any such severance. There is not, we believe, any such rule as that once made in London, in force in Edinburgh, and certainly not in Dublin.

On page 17 of the last edition of the "Register of the King and Queen's College of Physicians in Ireland" (compiled, we understand, by Dr. BELCHER), is this statement:—"Any Clerk in Holy Orders, or any Barrister-at-Law, if qualified in other respects, may become a candidate for the license; or, if a Licentiate of sufficient standing and qualification, may become a candidate for Fellowship; and any Fellow or Licentiate who may take Holy Orders, or be called to the Bar, continues to hold his collegiate position, so far as the College statutes and bye-laws are concerned." To this statement is annexed the following note:—"At present [1866] there are two Fellows, two Honorary Fellows, and three Licentiates in Priest's Orders of the United Church of England and Ireland. One Licentiate is in Deacon's Orders of the United Church, and one Licentiate is a Barrister-at-law."

Nor has the Church of England made any such severance between its clergy and our profession. It is well-known that a priest of that church may keep school and practice physic, while he may *not* engage in *secular* callings.

As historical facts, it is also known that many of the English clergy who refused conformity in 1662, supported themselves by practising physic, as did several of the non-juring clergy and bishops, who were staunch advocates of Church authority, at a later time.

The last of the non-juring bishops, whose name was BOOTHE, practised surgery, and died in Ireland in 1805; another, named CARTWRIGHT, was an apothecary in Shrewsbury, and died there in 1799; and a third, named DEACON, was a physician of note in Manchester, where he died, and was buried in St. Ann's churchyard, in 1753.

There is no canon or civil law, that we are aware of, connected with the Established Church, which prohibits a Clerk in Holy Orders practising medicine.

Dr. MEADOWS concludes his essay thus:—

"There is, methinks, something strikingly suggestive in the historical fact of S. Luke, the Physician, whose praise is in the Gospel, being called to be an Evangelist and Physician of the soul; and well might the Colleges of Physicians of our day with one heart and soul join with the Church in appropriately celebrating his Festival with holy joy, and praise, and thanksgiving. We have our commemorative festivals in honour of Hervey and Hunter, as shining lights in the regions of science; why not then of S. Luke, whom the Gospel exhibits as a pattern Physician? His recognition and commemoration would surely tend to elevate our calling now, as his Divine call undoubtedly did then. May the time be not far distant when such a recognition will be the spontaneous act of a body of men as truly united in one holy bond of Faith, as they now are in works of Mercy."

On this we can only remark that in Dublin, at least, this idea is neither strange nor new. In the Register of the Dublin College already quoted there is the following note on page 9:—

"At one time the College used to attend St. Luke's Church in this City on St. Luke's Day: '*Ordered*, that the Treasurer be directed to pay to Dr. Mitchel three half crowns, to answer the expence of printing the certificates signifying our meeting at St. Luke's Church.

"'*Ordered*, that the President and the two elder Censors do wait upon Mr. Campbell, and return him the thanks of the College for his excellent sermon, and that he be desired to print it at the expence of this College.

"'*Ordered*, that a piece of plate, not exceeding two guineas, be given to Mr. Campbell for his sermon preached before the College at St. Luke's Church.'"

Coll. Journal, 18*th October*, 1729.

"This sermon is to be seen in the College Library. It is printed in 4to., and has for its text a passage from St. Luke's writings—'In Him we live, and move, and have our being.'"

Notes on Current Topics.

The Public Health.

THE returns of the Registrar-General vary but little from those of last week. In London and 13 other large towns of the United Kingdom were registered 4564 births and 2787 deaths in the week that ended on Saturday, 23rd May—the annual rate of mortality being exactly the same as the last, 23 per 1000 persons living: distributed as follows:—21 per 1000 in London, 23 in Edinburgh and Bradford, 22 in Dublin and Bristol, 19 in Birmingham and Hull, 24 in Liverpool, 28 in Manchester and Glasgow, 26 in Salford, 29 in Sheffield, 25 in Leeds, 20 in Newcastle-upon-Tyne.

The deaths registered in London were 1252, being 74 less than the estimated number.

The deaths from zymotic diseases were 300. Thirteen deaths from small-pox, 64 from measles, 35 from scarlatina, 6 from diphtheria, 59 from whooping-cough, 38 from fever, and 19 from diarrhœa were registered.

One hundred and sixty-two deaths occurred from phthisis, 87 from bronchitis, 70 from pneumonia, 42 from diseases of the heart, and 151 from diseases of the brain and nervous system.

A child aged four years died of "Asiatic cholera" in 24 hours; 8 infants died from syphilis; 2 children and 2 adults from burns or scalds; 7 persons were drowned; 8 infants and 1 adult were suffocated; 5 persons committed suicide; and 3 were killed by horses or carriages in the streets.

Royal Geographical Society.

ON the 25th May last the anniversary of this society was held at Burlington House, Piccadilly—Sir R. J. Murchison, the President, in the chair. Several new candidates were proposed, among whom was Sir R. Napier, Commander-in-Chief in Abyssinia. The Secretary read the report, from which it appeared that the finances of the society were in a satisfactory state. The funded capital was £15,500, the whole of which will be required for the erection of a building for the society. A site has been promised by the Commissioners of Crown Lands opposite the Thames embankment. The President delivered his annual address on the progress of geography, during which he referred to the course of Dr. Livingstone in South Africa. From the date of his last letter, and a reference to the track he was pursuing, the hon. President considered that the great traveller might possibly reach England in August next. He spoke in eulogistic terms of the Abyssinian expedition, and concluded by returning his thanks to the society for the support it had invariably afforded him while performing his duty, and repeating that they should select a younger man to fill the distinguished post he had so long accepted. The anniversary festival was celebrated in the evening. The dinner was served in Willis's Rooms. Toasts were given and replied to by many of the noble and learned gentlemen who were present, after which the company retired.

British Association for the Advancement of Science.

THE Association has issued the preliminary circular of its thirty-eighth meeting, which will be held at Norwich on August the 19th, 1868, under the Presidency of Joseph Dalton Hooker, Esq., F.R.S., D.C.L., &c., Curator of the Royal Gardens at Kew.

The fact that Norwich has never before been visited by the British Association, the character of its manufactures, the highly interesting geological features and archæological remains in the surrounding district, with a hearty desire worthily to receive the association, will combine, we trust, to make the meeting thoroughly interesting and successful.

Norwich, from its short distance from London and the Universities of Oxford and Cambridge, is easily accessible to members desiring to be present.

The opening address will be delivered in the Drill Hall, on Wednesday evening, the 19th of August, at eight o'clock, by Joseph Hooker, Esq., F.R.S., D.C.L., &c., President elect. Soirées will be held in St. Andrew's Hall on the evenings of Thursday, the 20th, and Tuesday, the 25th of August. Evening lectures will be delivered in the Drill Hall, on Friday, the 21st, and Monday, the 24th of August, at half-past eight o'clock. Various excursions (geological, archæological, and ethnological) have been arranged to take place on Thursday, the 27th of August, to Cromer and its district, to Hunstanton, to Holkham, Castle Acre, Diss, Hoxne, Thetford, &c., full details of which, with times of trains, will be published in due course. Minor excursions, within a short distance of Norwich, are in course of arrangement, and will be notified at the time of meeting.

The Medical Council.

THE forthcoming meeting of the Council is looked forward to with a certain amount of languid interest, betokening how weak is its hold on the profession it so little represents.

Again and again have we pointed out how egregious a failure this same Council has been. But for some few men embued with liberal principles we should have no hope of it.

What with education, which is likely to be brought forward with considerable ability, and the perpetual attempt to tinker the Medical Act, we fear little time will be allowed to the one subject that interests the general practitioner, viz., the mode in which the reform of this Council can be effected.

The time is come when members must pronounce whether they will fight for things as they are, or accept the reforms that have been suggested.

St. Thomas's Hospital, London.

THE biennial dinner of old students took place last Thursday, under the presidency of Dr. Barker, at the City Terminus Hotel. Some 200 sat down to dinner, and we noticed with satisfaction a good attendance of the staff, and a very friendly feeling pervading the room, rendering this kind of renewal of intercourse evidently one that gave considerable pleasure to all parties. It was rather unfortunate that it was not possible to have the dinner the same day as the ceremonial of laying the foundation stone of the new buildings. We may, however, congratulate all concerned on the success of both events.

Army Medical Promotion.

THE letter of the Director-General of the Army Medical Department to Dr. Mackesy, which appeared in our journal this time last year, has elicited an elaborate reply printed in the form of a Parliamentary paper, and signed "One of Ten Years' Service." In his communication the Director-General stated that :—

"With regard to the returns laid before Parliament, the number of promotions in each year is not a reliable means of testing the probable rate of such promotion, inasmuch as, in such a calculation, no note is taken of casualties arising from other causes—such as death, resignation, and retirement upon half-pay, &c., all of which contribute to advance the juniors to the top of the list.

"I have to add that at present assistant-surgeons of twelve and a half years' service are getting their promotion, and that, considering they thus attain the relative rank of major, they are as a rule considerably in advance of their combatant brethren, and have, in consequence, no cause of complaint on this ground, which is not equally applicable to all other branches of the service."

"One of Ten Years' Service" endeavours to meet this statement by the reply that, as the number of Assistant-Surgeons for promotion above the survivor diminishes, so the chances of casualties become fewer, till, finally, his steps are reduced almost to those given by promotion only. But, in any case, it is evident that the Director-General's statement is perfectly correct, and that the vacancies for the promotion of assistant-surgeons, especially as long as they are low on the list, are entirely misrepresented by the Parliamentary return, which has been energetically and, we must add, disingenuously circulated by the discontented party amongst the army medical officers.

As long as the demands of assistant-surgeons constituted a just claim on the government, we exercised every influence in our power in their support. Now we believe that concessions have been made as far as the service either requires or permits, and we have no sympathy with a prolongation of agitation, which, we believe, has been the principle cause of the bad feeling of the military authorities towards army medical officers. Reform in the medical department is now converted from a legitimate demand for justice into an attempt to coerce the authorities by keeping back the candidates for appointments in the service. Surely "One of Ten Years' Service" must be "gravelled" for a grievance when he makes one out of the fact that an assistant-surgeon is "in a subordinate position," and that he is liable in the discharge of his duty to be sent to such places as Belge, Corosal, Honduras, the Mauritius, Gibraltar, and Malta. Is the cry to be "No foreign service and universal equality ?"

For all the exponent of the grumblers may say the fact remains that, since the late reforms came into force, the army medical department enjoys a sufficient supply of candidates for appointments, apparently as well educated and as eligible for the service as "One of Ten Years' Service." We venture to suggest that grievance-farming, especially when carried on by misrepresentation, will not meet with the sympathy of any more important class of assistant-surgeons than the "used-up" class who are incapable of adopting them to the roughnesses of their path in life.

The Aggregate Meeting of Poor-law Medical Officers.

THE proposed meeting of London and Provincial Poor-law Medical Officers, called by Dr. Rogers, and to which we have several times referred, has been fixed for June 24, at the Freemason's Tavern, at 2 P.M. We sincerely hope that it will be numerously attended, not only by Poor-law men, but by all interested in the state of the profession. We have to report, in connection with this, that it has been thought advisable that the proposed co-operation of the Medico-Political Association should only extend to its individual members lending such independent support as they deem proper. The meeting, therefore, will be conducted by friends of the Poor-law Medical Officers, under the leadership of Dr. Rogers. Mr. Clements, M.P., will preside on the occasion, and many eminent members of the profession will, it is hoped, lend their support to their over-burdened brethren.

Parish of St. Pancras.

WE have previously mentioned the many improvements that have been carried out by the guardians of this large metropolitan parish. The report of the Chairman of the Board (Mr. W. H. Wyatt) was issued last Wednesday as a Parliamentary paper. It is very complete and very satisfactory, and shows most fully the direction in which guardians may act to ameliorate the administration of our Poor-law. The St. Pancras Board has set an example which, we trust, may be generally followed. It is sad, but true, that such is the state of the Poor-law administration that we have to mention as a rare thing the fact that a Board of Guardians has shown itself both humane and enlightened.

Lyon and Home.

FROM the first day when the evidence in this case was laid before the public, we believe there was hardly any per-

son free from prejudice who did not see on which side the justice of the matter lay. The unvarnished fact remained, after all the conflict of evidence, that Mrs. Lyon made over her property to Mr. Home because, from his own representations, she believed in his supernatural powers. It is not at all necessary for us to believe (although there is hardly room for doubt on this point) that Mr. Home brought to bear, for his own objects, the influence of Mrs. Lyon's dead husband. It is sufficient for us to know that Mrs. Lyon made over her property to Home in consequence of her belief in his spiritual agency—that she would not have done so but for such belief, and that Mr. Home, by fraudulent representations, constituted to establish that impression.

There was, therefore, no escape from the decision that Mrs. Lyon had been "done" out of her money, except by the supposition that the spiritual manifestations were real scientific phenomena, of which Mr. Home was the honest exponent. Credulity has not yet been developed up to that point, and, of itself, the fact that the result of the manifestations was to put £60,000 in Mr. Home's pocket, is particularly persuasive for the public that the whole proceeding is a deliberate swindle—ghosts, the sole object of whose return across the Styx appears to be the frightening of imbecile old ladies in the interest of Mr. Home, cannot expect to receive recognition from the Vice-Chancellor.

By one excuse or another Mr. Home has contrived to wriggle out of investigation of his performances tendered by Professor Faraday, and now again by Mr. Tyndall, and this spiritualism being exposed both in its corrupt motives and its scientific falsity, is accepted after all as nothing but a trick put to bad purposes by its unprincipled authors.

Over the Alps.

Fifty years ago not a rail was laid down; not a locomotive was in existence; and when, subsequently, the great steam-horse was brought out and put into harness, it was thought necessary to level the roads. It would be hazardous to drive him down a decline, and there was no possibility of forcing him up. Viaducts were thrown across long valleys, and tunnels were cut through swelling hills. There was no help for it, and we were happy enough to avail ourselves of his untiring speed at any rate. But only a few years have been necessary to prove that he can go up hill, that he can go down, and that he can sweep round a narrower curve than ever was dreamed of with perfect safety. A railway train has been over Mont Cenis, by the road chiefly along which the diligence crawls at the rate of three miles an hour. On the 23rd May, one of the trains conveyed the Duke of Sutherland, Chairman of the Company, and 53 others interested in the undertaking, from Susa to St. Michel, where they dined in celebration of the enterprise. The opening of the line to the public is fixed for Monday next, the 8th June.

A Railway Tunnel.

Perhaps it may be an advantage in some respects to have twenty miles of sea flowing between our own and the French coast. At all events, it precludes the possibility of any quarrel on the boundary question. Still, there are inconveniences attending it. We seem to need, in the present state of our relations, a readier method of communication than is afforded by navigation. Several plans have been suggested. The most practicable one appears to be that of a tunnel for a railway underneath the bed of the sea, which is found not to be too deep to prevent the undertaking. A careful examination has been made of the soil on each side of the channel, and it is thought that a railway might be completed with no greater difficulty than is met with in works of that kind. Unless some unforeseen obstacles should prevent, it may be expected that the two countries will be connected in this manner before a great many years have passed away. Another design of a bridge, or succession of bridges, has been submitted to the Emperor by a French engineer. Whether it is at all likely to succeed it is impossible to say.

The Scotch Universities.

The Reform Bill for Scotland seems likely to remove a grievance, inasmuch as it will confer on medical graduates the privileges of electors in many questions from which they have been hitherto debarred. We have all along urged the claims of the Scottish Universities to larger representation than has been accorded, and we understand that our views have been pressed upon the authorities by influential parties. It will afford us pleasure to find they have succeeded, although, in the present state of the political world, we are not very hopeful of more than has been promised. It augurs well, however, that the justice of the case has not been refused a hearing.

Portrait of the late Mr. Cusack.

A fine portrait of the late Mr. Cusack, who died some years since, the father of Surgery, and one of the most esteemed and successful practitioners in Ireland, has been presented to the Royal College of Surgeons in Ireland by his son, Mr. Ralph W. Cusack. The portrait, which is most striking in its resemblance, was received by the Council on Thursday last, and was ordered to be placed at once in the Board-Room of the College, along with the portraits of Mr. Abraham Colles and Dr. Arthur Jacob, and a vote of thanks was passed to Mr. Ralph Cusack for his valued gift. Mr. Cusack was for many years Secretary to the College.

At the same meeting of Council, it was resolved that the portrait of the late Dr. William Kingsley, of Roscrea, the founder of the Royal Medical Benevolent Fund Society of Ireland, be moved from the Fellow's-Room to the Board-Room, which now contains the pictures of Dr. Rennie, who was mainly instrumental in obtaining the original grant for the building of the College, Mr. Herthorne, its first Secretary, Mr. Abraham Colles, Dr. A. Jacob, Mr. Cusack, and Dr. Kingsley.

ON SOME POINTS CONNECTED WITH THE PRESENT ASPECT OF MEDICINE, OR ON THE EXISTING STATE OF THERAPEUTICS.

By W. H. DAY, M.D., M.R.C.P.,

VISITING-PHYSICIAN TO THE INFIRMARY FOR CONSUMPTION, MARGARET-ST.

(*Read before the Medical Society of London, May* 4, 1868).

In an age when the plea of antiquity is not allowed to protect a creed or an art from the spirit of free inquiry; when in excess of all that is wholesome in this spirit, novelty and experiment are more attractive than the practical realities which science and experience have established, it requires much resolution in a speculative profession like that of medicine, to weigh cautiously the importance of each new theory before assigning to it any value, and to hold ourselves aloof from the adoption or recognition of any system, which has not true scientific principles for its basis, and honest men for its advocates.

In such an age it is not to be wondered at that the inviting allurements of homœopathy should have often dealt a heavy

blow to the use of legitimate medicine, and encouraged dissatisfaction with ourselves and our art; and, indeed, the fact that nothing exact can be laid down as reliable of disease, has infected even ourselves, and made us prone to stray from the path which has led to some success, and which would lead to still greater, if we earnestly and unflinchingly pursued it. If we inquire for a moment the cause of this, and how it is to be explained that many other false methods of dealing with disease have found supporters, I should say that we practitioners of medicine have in a great measure brought this on ourselves, by our uncertain utterances as to the value of medicines. One remedy after another has been declared by prominent members of our profession unworthy of any confidence, nay, now and then a voice is heard from amongst us, loudly declaring that remedy retards recovery, and but interferes with the efforts which nature itself is making to ward off the threatened attack of disease, or to combat the deep-rooted malady. In this respect the spirit of medical opinion can scarcely fall lower than at the present time; it has fallen so low that it is alarming to the very physician, whose own eyes have seen that mercury can cure syphilis, and bromide of potassium lessen the seizures of epilepsy; that oxalate of cerium, in large doses, can effectually stop the vomiting of pregnancy; and that quinine can arrest the paroxysms of ague. He beholds with dismay that one remedy after another is rejected and pronounced inert, after having reason to believe that he has saved life under their judicious administration, and that they exert a decided influence for good.

When I have seen a patient long suffering from a hard syphilitic tumour, attended with languor and cachectic misery, and with no chance, if left to himself, of any relief from his suffering, when in such a case I find that without changing any of the circumstances, I can, by the use of mercury, render the patient light and elastic, I can come to no other conclusion than that the mercury has been the cause of cure. I know of no other remedy with which we are acquainted that can effect this, and hence I say that we have a valuable remedy in the cure of certain forms of syphilitic disease. There are, however, many honest and independent observers, who would not subscribe to this opinion of the value of mercury, and who would assert that they have cured similar induration by other means. But even granting for a moment that there are other remedies, that does not affect the fact that mercury is an established remedy, and should be declared as such. Let me take another instance:—The tonsils are inflamed and covered with lymph, and suppuration is impending. Now, if we can ward off this crisis by painting the tonsils freely with the solid nitrate of silver, we infer, and rightly so, that the remedy has controlled the inflammatory action, and arrested further mischief.

So, again, if in the excitement of delirium tremens, when the aspect is wild, the skin sweating, and the patient sleepless and resisting food; if in this state a dose of opium tranquillizes the nervous system and brings rest and returning appetite, I say we are shown to have at our command a priceless drug, the value of which cannot be over-estimated. Let it be understood that I do not advocate the general treatment of delirium tremens by the opium plan. I merely give it as an example to illustrate my meaning. In order to increase our insight into disease, it is imperative that we come to some conclusion, whether remedies have a beneficial or a controlling effect, or whether, as some suppose, they may not frequently, from the dose in which they are given, have no effect at all. We have converts to all these doctrines; some, as I have said, insisting that drugs are almost valueless, and that nature is adequate to deal with disease, provided ordinary care and attention are bestowed on our patients; others insist that the timely administration of a remedy proves curative and renders the constitution less liable to future attacks. And again, I am not venturing too much when I say that there are really some who teach or think that medicinal agents are rather the tormentors than the antidotes of human suffering, and that the great lesson we have to learn is to wait and watch. Surely great and energetic efforts are needed to settle these discordant views, that medicine may have her true position; and we should proceed honestly and openly to work out the problem, for amid the convulsions of unsettled opinion and the calumnies of unscrupulous detractors, nothing satisfactory can be expected to result. Ours is a high and humanizing mission, and he is the noblest benefactor of our art who sifts the real from the unreal and the true from the false, and who deduces his opinions from the operations of nature rather than trusts to the fancies of his imagination and the shallowness of idle theory. Bacon has wisely remarked that "time is the greatest innovator," and it would be irreconcilable with human progress and invention if it were not so; but when changes are revolutionary and rapid, men's minds are not ready to receive them, and then ensue doubt and confusion and disorder, and the slow-growing tree of steady advancement is preferable, and when matured will bear a sounder and a richer fruit. The question I would put to you all is this: is there not a sufficient amount of medical theory which has been submitted to verification (in many unexpected ways, unforeseen by the original theorists), that is as impregnable from assault as the law of gravity has been rendered by the multitudinous discoveries of astronomy? In trying to answer these questions it has often struck me that if physicians were unanimously agreed on one method of research we should reap a richer harvest of information than we now do by reason of men going separately and antagonistically in the same field of inquiry, and then disseminating amongst us a crude and heterogeneous mass, from which nothing definite nor clear can be extracted. Now, the same constitutions, the same diseases, and the same influences are common to all observers; and so far it might be expected that some similarity of induction would result. But, on the contrary, it is rather the exception than the rule for *two* physicians to prescribe alike, although they might fully concur in their opinion of the case before them. One has great faith in remedies, the other has none; one physician sees fit to advise the discontinuance of treatment, when another, in all honesty and good faith, deems it necessary that medicines should be diligently persevered with. This contrary advice shakes the confidence of the public, and shows discord in our camp. If therapeutics could be reduced to something like precision and exactness (as ere long we hope will be the case), we should not find diseases so tossed by the tempest of medical opinion, for we quarrel with their treatment rather than with their essential nature. If long habit and fair results in the use of a few remedies have not shaken all our faith, we are gradually separating ourselves from them, and so the thousand-and-one quackeries of the day are flourishing. Our cases for the administration of drugs are not sufficiently analysed; some are amenable to them and yield at once; others do not yield sensibly to them, or they create additional constitutional disorder. For instance, I once saw a case of severe hæmatemesis from ulceration of the stomach, kept up by the exhibition of astringent and other medicines. The hæmorrhage was always increased, and frequently brought on by the use of drugs, but it became evident that the patient's life was in as much jeopardy from the use of medicines, as from the disease itself. For some days nothing but iced-water was taken in small and repeated quantities, and later a little milk was added, and so increased, till the ulcer was healed, and the stomach could bear the food and nourishment of health.[1] Again, I have seen diarrhœa over and over again kept up by drugs, when rest and repose of the irritated organs were alone needed to calm the excessive action of the bowels. Now, in both these cases the fault is not in the remedy, but the error either of selecting the drug, or of the disease for which it is employed. Uncomplicated diseases, not tending to organic change, are disposed to run their course to a satisfactory conclusion, with very little aid from medicine, where the bodily powers are good, and the patient is not awakened to alarm. The administration of proper food and nourishment, and perfect repose of body and mind are important agents in the overthrow of disease, and one of the great fallacies of the age is, that men trusting to medicines alone, have in too many instances disregarded these points. It has occurred to all of us to see this repeatedly, and to give a favourable prognosis accordingly. To carry a patient partially through an illness is often to combat its worst phases, and to place him in the most suitable condition for recovery. By arraying ourselves in hostile opposition to facts, we invite the scepticism of the public, and expose ourselves and our profession to obloquy and distrust. To disarm doubt and suspicion is to ensure confidence; we impress and convince where we are most candid and open, and admit our failures and defects. I do not consider we receive a new remedy in a fair manner—we do not weigh its value, and unwarped by prejudice, seek to find out the limits of its utility; we either adopt it blindly and enthusiastically, or we resist it altogether. It was so

[1] Since writing this paper, I have read two very interesting cases in the *Lancet* for April 25th, 1868, "On the Treatment of Ulcer of the Stomach," by Dr. B. W. Foster, of Birmingham. He recognises the therapeutic value of rest in medical as well as in surgical practice, and trusts to injections of beef-tea, milk, &c., in preference to pouring medicines and food into a sensitive and painful cavity. His views fully accord with my experience of the treatment of this affection.

with the Turkish-bath. A few years ago it took us by storm, and was held to be the great agent in the cure of disease, the eliminator of morbid poisons and inflammations of all kinds. It was to cure gout and rheumatism, epilepsy and insanity, asthma and consumption, paralysis, and a host of other formidable diseases. It had an ephemeral reputation, and gradually lost much of its popularity, and from the indiscriminate selection of cases, undeserved attacks were hurled against it. Looking at the question in an unbiassed light, and entirely from my own limited observation, I can testify that it is one of the most valuable agents we possess in the cure of many diseases in proper cases. A gentleman, 40 years of age, having reason to think a very acute attack of gout was coming on, prepared himself for the event. He went to bed, and was awoke in the night by the most excruciating agony in the foot; the part affected rapidly swelled and became vividly inflamed. In the morning he went into the Turkish bath at 190°, and remained in till the loss of perspiration was something fabulous. The next day he was free from pain and all discomfort, and his foot bore not the slightest trace of the invasion. He at once left London, and never felt in better health. Now, no colchicum nor saline purges could have so speedily and satisfactorily brought about a cure, and the patient being strong and vigorous, it was most adapted to his case. I could adduce many other striking examples.

There is, in all constitutions, a certain reserve force, which is drawn upon by the emergencies of disease more or less. He who possesses the most and least draws upon it, so much the better for him in the time of sickness and advancing life, but he who is always coming to it day by day to keep up his health, he who feels a necessity for this early loan, is taxing dangerously and immoderately the whole excretory apparatus of his body, and is draining his blood of its most important ingredients. It must be noticed that where this great drain is going on, the appetite is often craving and excessive, the tongue clean and pallid, the pulse soft and relaxed, the heart disposed to irritability, and murmurs of anæmia not unfrequently present. Where great purulent discharges are taking place, as in the expectoration of phthisis, and in the draining of chronic abscesses, so long as patients can eat well, and take quinine and porter, they bid defiance, as it were, to the progress of these complaints, but when the appetite fails, we know the activity of the disorganising process, and the rapidity of dissolution. These baths daily persevered in must abstract an enormous amount of fluid from the body, and it is in this way that gouty and rheumatic patients find relief. These are they who express most confidence in them, and who certainly are most benefitted, whilst the attacks are acute and active, and there is an abundance of adipose tissue. Here the skin, by doing a large amount of duty, relieves the internal organs, and helps to ward off the mischief which would otherwise accrue to them. But when these patients have experienced repeated attacks, and the joints are getting stiff and contracted, the baths aid the evaporation of the synovial fluid that is left, and before any relief is obtained, every ligament and muscle is relaxed and stretched to the utmost. I have adverted to this subject because many of my personal acquaintances are in the habit of using these baths without seeking medical advice. I think it must be admitted that we have a certain definite action in the treatment of these disorders by the Turkish-bath, which, in acute cases and strong subjects, effectually rids the constitution for a time of the *materies morbi* of gout and other allied affections, and with greater celerity, and with less cost to the sufferer than by other means, for there are no drugs with which we are acquainted that produce such a chemical change in the blood that shall cure the predisposition to these disorders. All the remedies that are recommended have an alternative and eliminative effect, in the same way that these high temperatures open the millions of pores in the human skin, and drain off

> " . . . the perilous stuff
> That weighs upon the heart."

Gouty inflammation seldom invades the joints so long as the skin and kidneys are actively performing their functions, and the pressure of the poison is not too great upon them. The disease may be lurking about in the system, although not showing itself by any local manifestations, or even giving rise to any appreciable discomfort. The vigorous functions of health are sufficient to purify the stream, and the patient goes on his course for months, and it may be for years, performing his accustomed routine of daily duty, but any indiscretion in diet, cold, anxiety, extra fatigue, or whatever causes may tend to upset the balance of his health, will be enough to provoke the enemy. There are many other disputed points in medicine which I should like to have touched upon, but the allotted time is nearly exhausted, and I must already have wearied you with the length of my observations. Sir, I am well aware that the hints and suggestions I have thrown out this evening are most imperfect, but I trust that they may prove suitable topics for the serious and unprejudiced consideration of the Fellows of this Society; many of whose minds are comprehensive in grasp, and subtle in reasoning, far abler to work out in detail questions that I can barely enunciate in the commonest words. And if I am fortunate enough to awaken the attention of any to the gravity of the questions I have cursorily glanced at, I shall rest assured that I have not occupied your attention in vain. Great facts in medicine are not the growth of to-day, nor of yesterday, they are the ripe fruit of diligent inquiry, directed in an even and unvarying course; they may be likened to the plant that is pruned carefully of all weeds and hurtful hindrances, till it has sprung forth and stood firmly and alone, destroying, by force of sheer exhaustion, whatever can retard its progress to perfect development.

MEDICAL SOCIETY OF LONDON.

MONDAY, MAY 11, 1868.

Dr. RICHARDSON, F.R.S., President, in the Chair.

Present—35 Fellows, 8 visitors. The following gentlemen were admitted Fellows by the President—John Brady, Esq., M.P.; Dr. Harrington Tuke, Dr. Hughlings Jackson, Dr. Richard Davy, Dr. Junker, and Mr. Geo. Gregson.

The PRESIDENT exhibited a reflecting stethescope, which he had invented. It combined a mirror for examining the throat, an ear speculum, and a stethescope, and was very portable.

Mr. HENRY LEE then referred to a subject which had been under discussion at a previous meeting. He had then stated three propositions, one of these was that no secretion elaborated in a gland in the human body would convey syphilis. The report in the journals, which was otherwise most correct, would make it appear that he had excepted the seminal fluid. He believed that the seminal fluid would not *per se* communicate syphilis, when it apparently did so he thought it was by the admixture with the secretions from the mucous membranes, and this would account for the fact that a father who was syphilitic would sometimes have healthy and sometimes diseased children.

Dr. SANSOM showed for the patentee, Mr. John Sörensen, an ingenious and simple self-cooking apparatus. It consisted of a box thickly padded with felt inside, and capable of holding a properly fitted saucepan or other cooking utensil. Mr. Mason had visited the patentees establishment at two o'clock on the day of the meeting, and had seen some beef-tea, Irish stew, and a veal-steak pudding put into cold water, and brought to the boiling point, at which they were kept for about ten minutes, the saucepans were then placed into the isolating apparatus, and Mr. Mason sealed the box.

At the meeting the seal was broken, when the pudding, &c., were found quite cooked, and as hot as if at the fire.

The PRESIDENT read a paper "On Animal Force" in further explanation of his views, and in answer to the exceptions which had been adduced by Dr. Broadbent, in respect of the use of the word attraction, which had been objected to, he (the President) did not care about the term. He contended that the term might be applied in the most absolute manner to express the relation between force and matter. On the question, what is the associated change in nervous matter when it becomes charged with force, the President said he might ask Dr. Broadbent what was the associated change in the matter of soft iron when it became a magnet, but he would prefer not to reason in this way. There was a distinct associated physical change in nerve-substances during recipiency of force, and that probably consisted in change of form or condition of matter, and change between the fluid and solid state of matter. If any change occurred in the nerve from electrical current, he premised it would be from electrolytic decomposition of animal matter.

Dr. BROADBENT, after thanking the President for his able address, said he could not yet accept his views, and hoped to bring before the Society, at some future time, a paper which would bring this subject under discussion.

Dr. SEDGWICK said, that in answer to Dr. Broadbent's objection that matter cannot attract force, he would instance the

case of a bright metallic mirror which would reflect rays of heat falling on it, and that if blackened it would absorb them ; in the former condition it might fairly be said to repel, in the latter to attract heat, the physical condition of the mirror being the cause of the difference.

Mr. ALFRED HAVILAND read a short paper "On the Effects of the Morbid Secretion of Milk," and related a case in which a perfectly healthy child, aged nine weeks, was seized with purging and vomiting immediately after taking an evening meal composed of asses milk, which had been yielded after a forced journey of many miles, during which the ass had been much maltreated. He thought that milk may become suddenly poisonous from some causes, and often gives rise to convulsions in children. In all such cases a complete change of diet was absolutely necessary.

Dr. ROUTH thought excitable people should not be employed as wet nurses, and believed that convulsions and other ailments of children, are due to the excessive acidity of the milk. Lime-water or soda would produce the desired alkalidity.

Dr. ANDREW CLARK in conjunction with Mr. PETER MARSHALL, "On a Case of Basic Complex Lung Disease resembling Phthisis." The case was that of a clerk, aged 26, who had had good health until 1863, when he caught gonorrhœa and orchitis ; he afterwards had a chancre, for which he was salivated, but he never had any secondary symptoms. In 1864 he began to experience a sensation of knives running into his right side, and in 1867 he was admitted into the London Hospital, with chronic pneumonia and gangrenous abscesses of right lung, and fibrinous pleurisy of both. The patient died in March, 1868. The author then gave the details of the post-mortem examination, and came to the very important question :—"What was the origin and nature of the patient's malady ?" He said that there were but two possible answers —one, that the local lung disease was the result of an ordinary inflammation ; the other, that it was set a-going by the transference of morbid matter from the diseased testicle to the lung. The author then referred to fistula in ano in connection with phthisis, and said that some observers consider the former the consequence of the latter, and others consider the affection as mere coincidences. He concluded a most interesting paper by giving it as his opinion and that of Mr. Marshall, that their patient's malady took its start from deposits and secondary inflammation, excited in the lung by the presence of septic or other matters carried from the diseased testicle.

In the discussion that ensued, Dr. BROADBENT remarked that many cases of so-called phthisis were not so, and he believed that in the case of fistula this disease, as a rule, preceded the lung disease.

The PRESIDENT agreed with the last speaker, and said that in a large experience he had observed that the fistula was antecedent to the lung disease.

Mr. HENRY LEE said he never was able to trace any connection between orchitis and lung disease.

The author replied, and the meeting adjourned.

Correspondence.

THE KING'S PROFESSORSHIP OF PRACTICE OF MEDICINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to call your attention to some unintentional inaccuracies in an article in your paper of the 27th instant, headed, "The King's Professorship of the Practice of Medicine in the University of Dublin ?"

The above professorship, at present held by Dr. Stokes, is *not* vacant ; that referred to in the article in question is probably "the King's Professorship of the Practice of Medicine *on the foundation of Sir Patrick Dun*," which is really one of the College of Physicians professorships, because the election and control of the professor lies solely with the Fellows of the College of Physicians, out of whose trust-estate he is also, paid, and by whom his duties are regulated. The University has nothing to do with him, further than giving him a lecture-room ; and even this connection may be severed at the will of the college aforesaid. Nor is the "consent" of the Board of Trinity College, Dublin, necessary, or even allowable, in an election of this kind. The Board have nothing to say to the matter ; and it surely must have been a *lapsus calami* of the writer to say that "the special function [of the University] is the conferring of *medical* degrees."

Further, there are *fifty-three* electors, and not *thirty-three ;* and of these fifty-three, forty-four are resident in or near Dublin. There are also more candidates, I believe, than those given in your article, and possibly there may be more still, before the day of election. As to the candidates named by your correspondent, I wish to say no more than this, that in the "Medical Directory" of the present year will be found a tolerably accurate account of their respective merits. The Directory does not, however, give an entirely accurate or complete account of the present official positions, and published works, of any one of them.

There seems to be a hopeless confusion of ideas about the professional connection between the Dublin University and the College of Physicians, notwithstanding various articles on this very subject in your journal during the year 1867. Not only is the professorship, to which your correspondent referred, not of, in, or belonging to, the University (any more than Dr. Benson's Professorship in the College of Surgeons), but it is actually not even *the* Professorship of Medicine on Dun's foundation ! By the Acts of 1800, and 1867, there are *three* Professors of *Clinical* Medicine in the School of Physic. All in turn teach clinical medicine, while to one is confided the special teaching of the "Institutes," or theory; to a second that of the *practice ;* and to the third, that of the means or instruments whereby the theory is to be carried into practice—Materia Medica, &c. Irrespective of this view, however, there are at least *two* Professorships of Medicine on Dun's foundation : one now held by Dr. Law ; the other lately held by Dr. Banks.—Yours truly,

A MEMBER OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

28th May, 1868.

[We were well aware of the distinction between the Professorships held by Dr. Stokes and Dr. Banks, and adopted the title to which our correspondent properly takes exception, with the view of simplifying to the understanding of those who know nothing of Sir Patrick Dun's foundation, the somewhat incomprehensible distinction. If we had been writing of Dr. Stokes we should have used the usual title of "Regius" Professor. We were aware that the selection of a Professor lies solely with the Fellows of the College of Physicians, but, we presume, that as the future efficiency and success of their school will turn on the selection of an efficient Professor, the governing body of Trinity may be supposed to exercise a powerful indirect influence in the matter. We cannot, however, believe that the many influential physicians, who are electors in this case, will vote at the dictation or influence of any extraneous body, or of any individual, however powerful. To put in a novice would certainly bear this interpretation ; while it would stultify their own professional claims in the eyes of the public.—ED. M. P. & C.]

CHYMISTS AND DRUGGISTS.—Lord Granville has laid before the House of Lords a Bill proposing to enact that after the 31st of December, 1868, no persons shall keep open shop for retailing, dispensing, or compounding poisons, or use the title "chymist" or "druggist," unless he is a pharmaceutical chymist, or was before that date in business as a chymist and druggist keeping open shop for compounding prescriptions, or has for two years before the passing of this Act been apprenticed to a chymist and druggist, or at the time of passing this Act being of full age has been actually engaged in compounding prescriptions as an assistant. An annual register of qualified persons is to be issued. Poisons are to be distinctly labelled. The Bill is not to extend to wholesale houses, or to sales for use in photography, or to patent medicine vendors, or to qualified medical practitioners or veterinary surgeons. Chymists and druggists are not to be liable to serve on juries. The following are to be declared poisons :—Arsenic and its preparations, oxalic acid, prussic acid, chloroform, cyanides of potassium and mercury, strychnine and all poisonous vegetable alkaloids and their salts, aconite and its preparations, emetic tartar, corrosive sublimate, belladonna and its preparations, essential oil of almonds, unless deprived of its prussic acid, cantharides, and savin and its soil.

THE VACANT CHAIR OF MEDICINE IN DUBLIN.

The election of a successor to Professor Banks, to which we called attention last week, is anxiously looked forward to, and the relative claims of the candidates are ardently discussed. To the names of Dr. Henry Kennedy, Dr. William Moore, and Dr. Foot, we have now to add that of Dr. Freke, whose candidature we had previously announced, and to whom we owe an apology for the omission, on inaccurate information, of his name, in the enumeration of the candidates.

Dr. Kennedy is Physician to Sir Patrick Dun's Hospital and to Cork-street Fever Hospital. Dr. Moore is Physician to Sir Patrick Dun's Hospital, to Mercer's Hospital, and to the Children's Hospital, and Lecturer on Practice of Medicine in the Ledwich School. Dr. Freke is Physician and Lecturer on Practice of Medicine to Steevens' Hospital, and late Physician to the Kilmainham Hospital. Dr. Foot is not, nor, so far as we are aware, has he been connected with any Hospital or Dispensary, nor is he a Lecturer, except in his capacity as Demonstrator in Anatomy.

As regards professional standing, Dr. Kennedy has been for nineteen years a Fellow of the College, and has been a Bachelor of Medicine for twenty-nine years. Dr. Moore is a Bachelor of Medicine of eighteen, and a Doctor of eight years' standing—a Fellow of the College since 1859, he has filled the office of Vice-President, and is at present an Examiner in the College of Physicians. Dr. Freke has been qualified as a Bachelor of Medicine for twenty-three years, an M.D. for thirteen, and a Fellow of the College for eleven; he also has been a Censor and Examiner. Dr. Foot has been a Bachelor of Medicine for six, a Doctor for three, and a Fellow for two years, and has held no office in the College connected with *the practice of medicine.*

The foregoing facts leave no room for further argument as to the relative fitness of the senior and junior candidates, and if the intention to set aside either Dr. Kennedy, Dr. Moore, or Dr. Freke for the advancement of Dr. Foot be carried out, the plea of that gentleman's superior eligibility can hardly be raised. The three senior candidates are physicians of standing and experience, and are known to the profession as competent teachers; and their personal claims, as Fellows of the College of Physicians, are many years in advance of those of their junior competitor. Their exclusion, therefore, to make way for the advancement of a gentleman claiming, in no respect, as far as we know, a greater title to the consideration of the College, would be not only an absolute slight to them and to their professional position, but would leave upon the public mind the impression, that in the contest for the honours at the disposal of the College, industry, experience, and capability, are weaker weapons than the judicious and timely "cultivation" of the powers that be.

At the Levee, on Saturday, held on behalf of her Majesty by H.R.H. the Prince of Wales, the following members of the Profession had the honour of presentation:—Dr. G. Butler, Dr. J. Campbell, R.N.; Mr. R. W. Davies, Dr. A. Garden, Dr. Francis Hawkins, Dr. Africanus Horton, Dr. Leonard, Dr. Meryon, Mr. D. Michael, Dr. Peake, Dr. Arthur Priest, Mr. Randall, Mr. A. M. Rogers, Dr. Seward, Dr. Stovell, &c.

The West Middlesex Coronership.—This case—Farnell *v.* Diplock—in the Court of Queen's Bench, will, by arrangement, be taken to-morrow (Thursday).

ELECTION OF THE COUNCIL AND OFFICERS OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

The first Monday in June is constituted by Charter the day for the election of the executive of the College for the ensuing year, and that day is adopted by common consent for the annual visit of the provincial Fellows to Dublin, and for the annual meetings of the Irish Medical Association and Royal Medical Benevolent Fund Society. The President, Mr. Adams, offered himself for election into the Council, and was replaced in the presidental chair by Mr. Porter, who, in his promotion from the Vice-Presidency, was succeeded by Mr. Macnamara. In addition to the out-going Council who offered themselves for re-election, the honour of a seat was sought for by Mr. John Hamilton, Surgeon to the Richmond Hospital, Mr. Stapleton, Surgeon to the Mater Misericordiæ Hospital, Dr. Kirkpatrick, Surgeon of the North Dublin Union, and Mr. Tyrrell, Surgeon to the Mater Misericordiæ Hospital. The following gentlemen were, on scrutiny of the ballot, declared duly elected:—

President—G. H. Porter.
Vice-President—Rawdon Macnamara.
Secretary—W. Colles.
Council—

William Hargrave.	Edward Ledwich.
James Barker.	William Jameson.
William Colles.	Alexander Carte.
Robert Adams.	James H. Wharton.
Hans Irvine.	George W. Hatchell.
Samuel G. Wilmot.	Albert J. Walsh.
Richard G. H. Butcher.	Edward D. Mapother.
Thomas L. Mackesy.	William A. Elliott.
Hamilton Labatt.	Archibald H. Jacob.
Benjamin M'Dowel.	

THE MEDICAL MEETINGS IN DUBLIN.

The meetings of the Irish Medical Association and the Royal Medical Benevolent Fund Society, on Monday last, were eminently successful and encouraging to the supporters of each of these valuable societies. Each was attended by a large and influential section of the provincial and metropolitan members of the profession, and the Council of each had to report a considerable accession to the members. The prosperity of these Societies is a certain indication of activity and prosperity in the profession, and we trust to be able to record a steady advance in at least the same proportion in future years as we are enabled to do to-day.

ON EXSECTION OF THE HEAD OF THE FEMUR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—May I take the liberty of directing the attention of the Profession to the above operation.

In the *Medical Mirror* for May, under the heading "Surgical Opinion," there is extracted from the *Pacific Medical and Surgical Journal* for March, 1868, published in San Francisco, three cases by Dr. David Wooster.

First.—Exsection of the head of thigh bone; removal of portions of cotyloid walls; recovery in one year, with a useful limb and joint.

Second.—Hip-joint disease in first stage; section of adductors; straightening under chloroform; cure.

Third.—Fracture of neck of femur.

Dr. Wooster considers that discolation seldom or never takes place in hip-joint disease, and after he cut down on the joint found it impossible to discolate the head of the femur till he had divided the tendons inserted into the great trochanter.—I am, &c., L.R.C.S.I.

The Secretary of the British Medical Association requests us to state that "the report of the sub-committee appointed to consider the representation of the Profession in the Medical Council," inserted in our last number, emanated from a sub-committee of the above association; and that a deputation has been appointed to wait upon the General Medical Council during their next session.

Medical News.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The following gentlemen obtained the Licenses in Medicine during the months of January, February, March, and April last:—

William Ahern, Liskeard, Cheshire; Oliver Stokes Eagar, Tralee; Thomas Greenhalgh, Manchester; Samuel Morton Hewitt, 25, York-street; Robert Todd Huston, Carlow; Charles Edward Jones, 53, Eccles-street; Albert Kirwan, 44, Mountjoy-square; Maurice Knox, Ballybrack; Francis Edgeworth Lynch, Drumcondra; Wm. McMullen, 3, Edward-terrace; Charles Benjamin Mosse, Staff-Surgeon; Frederick Robert Paterson, 14, Lansdown-road; Gregory Sale, Coolcor; William Henry Stock, Clonroche; Charles Joseph Walsh, Castlebar.

The following obtained the License to practice Medicine:—

William Akerman, London; Arthur Thomas Birney, 26, Middle Gardiner-street; John Annesley Brownrigg, Kingstown; Charles Alex. Cameron, 102, Lower Baggot-street; Wm. Henry Harding, Eastbourne; Edward Husband, Middlesboro'; Charles Boromeo Jennings, Ennis; Andrew McMunn, Ballymote; Francis Richard O'Grady, Ballyhannis.

The following obtained the License in Midwifery:—

Thomas Charles Gilmore, Ballybay; James Leathem, London; Daniel Thornton, Kinnetty.

LIST of Entries in the Branch Medical Council (Ireland), for the month of May, 1868:—

William Cooke, Garey, co. Wexford, Lic. Apoth. Hall Dubl., 1868; William Henry Stock, 56, Camden-street, Dublin, Lic., 1868, and Lic. Midwifery, 1868, K. Q. Col. Phys. Irel., Lic. Fac. Phys. and Surg. Glasg., 1867; Francis John O'Reilly, Rathmore House, Athboy, co. Meath, Lic. R. Col. Phys. Edin., 1868, Lic. R. Col. Surg. Edin., 1868; George Corry, 3, Osborne-terrace, Kingstown, co. Dublin, Lic. R. Col. Phys. Edin., 1868, Lic. R. Col. Surg. Edin., 1868; Gregory Sale, Coolcor, Carberry, co. Kildare, Lic. R. Col. Surg. Irel., 1868, Lic., 1868, and Lic. Midwifery, 1868, K. Q. C. Phys. Irel.; John Byrne Hackett, Johnstown, co. Kilkenny, Lic. R. Col. Phys. Edin., 1868, Lic. R. Col. Surg., Edin., 1868; William M'Mullen, 3, Edward-terrace, Dublin, Lic. R. Col. Surg. Irel., 1867, Lic., 1868, and Lic. Midwifery, 1867, K. Q. C. Phys. Irel.

LORD BROUGHAM'S FUNERAL.—An Edinburgh gentleman, travelling in the South of France, in a letter dated "Cannes, May 24," writes—"This afternoon, at five o'clock, the remains of Henry, Lord Brougham, were conveyed in a plain deal coffin, covered with black cloth and nailed down with plain black nails, without any ornament or superscription, carried in a musty old hearse dragged by two sorry horses, to the public cemetery at Cannes, and pushed into a vault so clumsily that part of the black cloth was torn off the coffin. A clergyman read the customary prayers at the mouth of the vault, and then laid on the coffin two of those common wreaths of immortelles; then a Frenchman stepped forward and read an empty eulogium, the gist of which was that Lord Brougham had been the means of bringing the English to Cannes. A motley collection of odd-looking vehicles followed the hearse, containing Lord Brougham's relatives and friends. There were also some Frenchmen, and the remnant of the English whose avocations do not allow them to leave the place with the fashionable world. When we arrived at the cemetery, we found a crowd of peasantry—men, women, and children. I followed the hearse the whole way; it was a hot and a long walk."—*Scotsman.*

ROYAL MEDICAL BENEVOLENT COLLEGE.—The annual general meeting was held on Friday week at the offices of the college, Soho-square, under the presidency of Sir Chas. Locock, Bart. The Secretary, Mr. Freeman, read the report, which regretted the loss of their first treasurer, the late Mr. John Propert, as well as three old friends of the college—viz., Sir Thos. Phillips, Q.C., Mr. Joseph Ward, and Dr. Edward Ray. One hundred guineas had been set aside from the general funds of the college for a marble bust of the late Mr. J. Propert, which was to be placed in the college at Epsom. The commission for the bust had been given to Mr. E. W. Wyon, who had been well acquainted with Mr. Propert, and had modelled a bust of him in his lifetime, which was considered an admirable likeness. Mr. Wyon was now at work at it, and expected to have it finished early in the summer. There would be no election of pensioners this year, as no vacancies had occurred, but the usual annual election of foundation scholars would take place at the Freemasons' Tavern during the present week, when ten boys would be elected. The number of applicants was large, their being no fewer than 51 for the ten vacant places. The report then complained that boys were sent to the college utterly unprepared for the course of studies appointed for the students. The council had therefore made arrangements for these lads to be prepared at a school at Epsom, under the tuition of Mr. Davy, a late master of the college. The council considered that the friends of the college had every reason to be thankful for the success which had hitherto attended it, and to look forward with courage and confidence to the future. The balance-sheet showed that the receipts from all sources during the year had been £12,034, 11s. 11d.; and after all the expenses had been paid there remained a balance of £921, 16s. 7d. Dr. Carr moved, and Mr. Dale seconded, the adoption of the report, which was carried unanimously. The members of the council who retired were re-elected, and a vote of thanks to the chairman and the officers closed the proceedings.

PRISON DIET.—An inquiry was lately held by Dr. Lankester, coroner, at the House of Correction, upon the body of Joseph Powers, a blacksmith, aged 45, an inmate of the prison, who died on the 20th inst. Maria Powers, of North-buildings, Hoxton, said the deceased was her husband. On the 20th of May, 1867, he was committed for embezzlement, and ordered to suffer 12 months' confinement. She saw him every three months, and he complained very much of the treatment, and said the food was not sufficient to keep him alive. He had been glad to purloin pieces of tallow candles and eat them, or he should have died of hunger. He said other prisoners had done the same, and when found out had been punished for it. He many times had said bitterly, "Oh, you little know what we have to suffer." The deceased was a corpulent, heavy man, and a great eater. She thought the want of sufficient food had been his death. He died on the 20th inst., after having been in the infirmary for six weeks. He was kindly tended while there, and died the day after he should have left the prison. A juror said he knew a man still in the prison who had lost 18 lbs. in weight of flesh during three months. The Coroner said there was a deficiency of fatty substance in the food supplied, and that might have made the deceased, who was a stout man, take the fat. Joseph Leeds, warder and nurse, deposed to the deceased being admitted to the infirmary on the 8th of April through spitting of blood, and that he received every attention. He had eggs, wine, and fish, but he gradually sank and died on Wednesday last. Mr. Smiles, the prison surgeon, said the deceased worked at the treadwheel for only a short time after his admission, when he complained to witness and he was excused. He was excused the wheel because he was a large, heavy man, and besides which he obtained two good conduct stars. He complained of the food, and witness ordered him an extra allowance. He had never heard of prisoners eating tallow, and gas was almost universally used in the prison. The witness had heard of prisoners eating soap but that was for other reasons. He had been told he was a great eater. The deceased had certainly lost flesh, and that was why he had ordered him an extra allowance. The coroner remarked that the subject of diet given to prisoners was one which the public are at present most anxious about. It was not right that prisoners should be punished by short allowances. Mr. Smiles said they had recently begun to weigh the prisoners once a month instead of once in three months. The only thing that deceased complained of was the want of food. In many prisons they gave no meat at all to prisoners, and he believed the authorities were reconsidering the question of diet. A verdict of "death from natural causes" was recorded.

NOTICES TO CORRESPONDENTS.

Mr. W. B. STOTT, Disley.—The result of the election for the Foundation Scholarships at the Royal Medical Benevolent College will be found in our advertising columns.

ONE INTERESTED.—See previous reply.

E. S., Manchester.—The publication of "Dr. Letheby's Lectures on Food" has now finished. They have appeared exclusively in this Journal, and we believe it is not the intention of the author to reprint them in pamphlet form, as you suggest. The whole of the numbers containing them—fifteen in all—can be had through any bookseller, or direct from our office.

MONOMANIA will oblige by forwarding his name and address, as a voucher that the extraordinary *facts* he would have us lay before our readers are correct. Our correspondent must not imagine that by adhering to this oft-repeated rule, we wish to cast doubts on his statement.

Proofs reaching authors in England on or before Friday morning are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper *only*.

HISTORICAL SKETCH OF THE DISMEMBERMENT OF PHARMACY FROM PHYSIC.

By M. DONOVAN, M.R.I.A.,

HON. MEMBER OF THE PHILADELPHIA COLLEGE OF PHARMACY.

[SECOND COMMUNICATION.]

In the British isles, and in some other parts of Europe, pharmacy had been long in a singular state of confusion and dangerous disorganization. Medicines were sold by barbers, grocers, and apothecaries. Between the trades of the two latter there was little difference; both sold nearly the same commodities. The apothecary could supply liqueurs, chocolate, tea, coffee, the ingredients of an electuary or a pudding, or of a posset of spiced wine; and the grocer sold sugar, fruits, drugs, and what were called the "public medicines." The physician in his prescription referred to these last in a very brief manner, on the supposition that use had made them familiar (Observations on the case of Rose); and it had been the custom to sell them at a certain known price. The composition of these was dictated by the physicians, and the apothecaries were required to compound them with the greatest exactness. Their uses and prices were communicated by the physicians to all families, and the nobility and gentry had their receipt-books, in which their management was described. Some persons made collections of receipts for their private use. There is still in existence an old black-letter book of this kind, which was published in 1639, from a manuscript that had belonged to a lady then lately deceased. The editor informs us that this manuscript was originally written for the lady's own private use, and that he found in it such "pretty conceits" that he felt it his duty to publish them. The book is entitled the "Widowe's Treasure." One of the pretty conceits is a receipt for phymosis, another for gonorrhœa, another to act as a diuretic; all expressed in plain English, that cannot be quoted.

These public medicines were bought in large quantities, and kept in every house as a domestic store; and when occasion required were mixed and divided at home into juleps, boluses, and powders, under the instructions of the physician. The public medicines, as bought from the apothecaries, were for the most part sufficiently compounded for use; but when the peculiarity of the disease required a variation of the formula, the physician himself prescribed, prepared, and supplied the article. These nostrums were called "reserved medicines" or specifics, and were kept secret from the apothecary. The physicians kept the articles necessary for these purposes in their houses, and even imported the capital medicines. Sometimes, on emergencies, separate articles were sent for from the apothecary and compounded in the house of the patient by the instructions of the physician. The physicians also, as now, received patients at their houses, and wrote extemporaneous prescriptions, to be sent to the apothecary. In these days it was nothing unusual for physicians to have salaries from families.

In England, up to the commencement of the reign of Henry VIII. (1509), any person, no matter how ignorant, might practice physic, surgery, or pharmacy; but the evils arising from such a state of things had increased to such an extent that the interposition of power was no longer a matter of choice. In the third year of the reign of that monarch an Act of Parliament was passed, from which we learn that "smiths, weavers, cobblers, draymen, and women boldly take on them great cures, and things of great difficulty, in the which they partly use sorcery and witchcraft, and partly apply nervous and unfit medicines, to the high displeasure of God, great infamy to the faculty, and grievous hurt of many of the King's liege people; most especially those that cannot discern the cunning from the uncunning." It was therefore enacted that no person in London, or within seven miles, should practise as physician or surgeon, unless first examined, approved, and admitted by the Bishop of London or Dean of St. Paul's, calling to him four doctors of physic, and for surgery other expert persons in that faculty, under penalty of one hundred shillings for every month's practice proved.

In the 10th of the same king's reign a perpetual College of Physicians was erected in London by Royal patent, in imitation of well-governed cities in Italy and other countries. This patent was nominally confirmed by Act of Parliament in the 14-15th of same reign; but by some unaccountable neglect the parliamentary roll was never signed with the royal assent, and hence became a dead letter.

In 32 Henry VIII. (1540), an act passed giving power to physicians to search all apothecaries' shops for bad medicines, and confirming to them the ancient privilege of prac-

tising physic in *all* its parts. By the law of England, therefore, the physicians were created general practitioners of medicine, such as we now find them.

In the first year of Queen Mary (1553), the privileges of the College were confirmed and extended. They were armed with the unjust and arbitrary power of fining and imprisoning their own members for *mala praxis*, or such as they chose to designate as such, and this without bail—a power which no king of England ever possessed. It was also enacted that the Censors of the College shall have power to examine the medicines in apothecaries' shops, and to destroy all unsound articles.

But the apothecaries, not relishing this interference of the physicians, whose education, however good in other respects, did not qualify them for this particular duty, in some instances resisted the Censors: insomuch that in 1553 (1st Mary) power was given to the president and censors to inflict fines and imprisonment on such persons as resisted them in their search of "pottecary wares." In a few years after this (4th Mary) all apothecaries were enjoined to expose the several ingredients of which a medicine was composed to open view for six or eight days, that the physicians passing by might judge of their goodness. Could anything surpass the absurdity of this law? This is the origin of the practice still prevalent amongst apothecaries and chemists of having their windows crowded with medicines of all kinds. But the charter of James I. (1618) transferred power of inspection from the physicians to the corporation of apothecaries, who might burn all bad medicines found. This stupid piece of legislation was borrowed from the edict of Frederick II., in the beginning of the 13th century, by which, in the southern parts of Italy, the apothecaries' *stationes* or shops were made liable to examination by physicians. This edict will be hereafter noticed.

Notwithstanding the efforts of the College of Physicians to protect themselves and the public from dangerous encroachments, London was overrun with pretenders and impostors, and were countenanced by persons of exalted station. The public at all times, down to the present, have evinced an unaccountable predilection for cures by old women. History records that the Duke of Buckingham, having dismissed the physicians who attended King Edward VI., put him under the care of an old woman. He died shortly after (1554). Pasquier tells us that the cavalliers, when wounded, had recourse to the nearest mansion to be cured by the women. The newly-chartered College of Physicians determined to exercise their powers vigorously, and to make examples of such as were found offending; but eventually it proved no easy matter, in consequence of opposition from unexpected quarters.

They warned their officers that "many lewd, indiscreete, and unlearned persons are wandering about with changeable names and false medicines." The College having restrained an old woman from practising as physician and surgeon, Sir Francis Walsingham, Secretary of State (Elizabeth) wrote a letter to the College, stating that by the application of certain simples, in the use of which "God had given her an especial knowledge, to the benefit of the poorer sort, I shall therefore desire you forthwith to take order amongst yourselves for readmitting of her into the quiet exercise of her small talent, lest you procure inconvenience thereby to yourselves." But the College expressed a respectful resolution to persevere. A quack, named John Not, being bound over not to practice physic, Secretary Walsingham interfered, as Not had been employed by himself and many gentlemen, and had received benefit from him. The College, however, persevered. The secretary having again interfered in the case of an illegal practitioner, on being expostulated with, hypocritically declared that if at any time, by the importunity of friends, he interposed, the College should act as they deemed prudent. In other cases the Queen herself interfered, but, much to the credit of the College, in vain. The attorney-general also ineffectually exerted himself in favour of a clergyman who had bargained with m[illegible]s, and took money in hand, but did no good. In one case he gave an emetic which produced 100 stools, and the patient died "wallowing in his sanguineous evacuations."

A surgeon, named Read, examined by the College of Physicians, being asked what was a diarrhœa, said it was a flux of blood from the womb, proceeding from gross humours in the stomach. He was fined and imprisoned. On this occasion, Chief Justice Sir John Popham, declared that he thought it most advisable that all physicians, for the future, should write upon their prescriptions the patient's name, and the day of the month and year—an excellent advice a long time acted on, but now, unfortunately, little attended to.

Long before this time the punishment of a quack was ridicule, he was set on horseback, his face to the tail, which he held as a bridle, a collar of jordans about his neck, a whetstone on his breast, and amidst ringing of basins, he was led through the city of London.

The regular apothecaries always defended their infraction of the law, by declaring that if they did not practise the consequences to the poor would be ruinous, inasmuch as they said "the physicians were not very ready to attend any patient that had not his guinea or his half-guinea in his hand." In order to prove their great utility to the public, they declared that while *they* stood their ground, during the plague of 1665, which carried off 68,000 citizens, the physicians deserted their post and fled the city ("Reason in Season," Hargrave, 1676). This charge seems to be in part true, for we find that in August, 1665, when the plague raged in London, a kind of proclamation was issued by two physicians chosen by the College, along with six others, for the prevention and cure of that pestilence, in which they direct all apothecaries to repair to them, "or any other of our profession *in town*, being not so *void* of physicians as generally reported," for advice, "as in former cases *they were wont*." Did the doctors decamp during former plagues also?

With regard to the charge made by apothecaries of the exorbitant fees demanded by physicians from patients of even small means, the physicians retorted the extravagant prices charged by apothecaries for medicines supplied to the poor; and, in 1691, they appointed a committee to communicate with the Lord Mayor and Court of Aldermen, to convince them of the necessity of putting an end to the oppression of the poor by the apothecaries. A committee was appointed; and the physicians undertook to prove to them that all the medicines in the pharmacopœia were very cheap: on which the sages of the city resolved that the physicians should affix a price to the medicines contained in their prescriptions, by a rate settled between the committee and the physicians.

Some months after this, the apothecaries had a meeting at their Hall: they resolved that every trader is best able to determine the value of his commodities, and they, therefore, indignantly rejected the assumed right of setting a price upon their services. At last, forty of the more tractable apothecaries obsequiously obliged themselves by their signature at the College, to deliver all medicines at the rates affixed by the prescriber; but they were called before the Hall, and threatened with chargeable offices, and expulsion if they did not retract. On this, the committee of the Aldermen and Commons requested the College to provide a repository for medicines where a reduction of prices could be carried into effect; but the proposal was not immediately acted upon.

The physicians had, long before this time, obtained an exemption from serving in the offices of constables, scavengers, and some other parish offices; their legitimate services to the public had been acknowledged from the time of the Trojan war to the days of the apostate Julian, who flattered them by a declaration that "their art came down from heaven," (see his letter in La Bletterie Histoire).

About the beginning of the seventeenth century, there was a physician practising in London, for a while chief-physician to Queen Elizabeth, and afterwards to James I., who was the originator of a complete revolution in the

practice of medicine in the British isles: this was Sir Theodore Turquet de Mayerne, a Swiss—a man of learning, influence, and wealth—of whom the following account has been given:—He obtained his degree of M.D. in 1597: went to Paris, and applied himself very much to chemistry, a science then very odious to the physicians of that city, who railed vehemently against him, representing him as a sworn enemy to physic. The faculty prohibited him by a decree from practising; yet Henry the Great made him his physician. After the assassination of this prince, Mayerne retired to England, made a great fortune, and was first physician to James I., as well as his friend and favourite. Loaded with honours, his fortune still increased under Charles I., and he was unanimously admitted doctor of physic in both universities of the kingdom. His reputation and practice were extraordinary (Bayle. Hist. Dict.). Disapproving of the English practice of prescribing the stock medicines and mixing them at the house of the patient, Mayerne, who had now received the honour of knighthood, used operose formulæ, which he called magistrale preparations, and which puzzled the apothecaries and grocers exceedingly.

Every medicine was disguised from the patient contrarily to the English practice, and amidst a multiplicity of trivial articles there was generally some active preparation. The court physician, of course, had his imitators, and the practice of a more complex extemporaneous pharmacy, by written prescription, began to gain ground; from whence, in a modified state, it has descended to us. The blunders and fatal mistakes made by grocers and some apothecaries, suggested the idea to Mayerne, of separating the apothecaries from the grocers, in order that the former, no longer distracted with the details of a business foreign to medicine, might apply themselves with better effect to the diversified processes of pharmacy. The College, no doubt, wishing to relinquish some of the more troublesome parts of the profession, coincided in this view; and a petition was addressed to his majesty by Sir Theodore Mayerne, and the king's other physician, Dr. Henry Atkins, praying his majesty to incorporate the apothecaries separately, and representing that, many persons sold medicines who were ignorant of their nature and qualities. His majesty, complying with the prayer of the petition, disunited the two corporations after an union of eleven years, and granted a separate charter (1617) to 114 apothecaries, who had been selected by the College of Physicians, as the best instructed of the grocer-apothecaries.

It was also granted that no one shall sell compound medicines in London, unless he shall have served seven years to an apothecary, and shall have been examined and approved by the master and wardens of the company. But as no penalty was attached to this clause, it was soon after totally neglected, and every one that chose opened an apothecary's shop in the city, without hindrance.

The College of Physicians having now the use of a sufficient number of legally qualified *servants*, for such they designated apothecaries, were not slow in calling their skill into action. In the next year (1618), they published their first pharmacopœia, which, soon after, was followed by a royal proclamation enforcing the observance of it in the composition of medicines (Rymer's Fœdera, 1618 and 1620). This pharmacopœia was compiled from Mesue, Galen, Rhases, Nicolaus, Actuarius, Avicenna, Valerius Cordus, Arnoldus, Gesner, &c. The oppression inflicted on the apothecaries by it was truly tyrannical, and made them pay dearly for the favour conferred on them by incorporation; for in its catalogue there are no less than 1254 articles, for which the apothecary was liable to be called on.

Whatever the motives of the College of Physicians might have been in procuring the separate incorporation of the apothecaries, it was decidedly one of the most impolitic measures for their own interests that they could have conceived. They were not slow in discovering their indiscretion, and were the more incensed at the consequences by discovering that the cause was attributable to themselves. The demeanour of haughty superiority assumed by the physicians towards apothecaries, tended, in process of time, to destroy the foundation of their own pride. The physician visited his patient attended by the apothecary, at first in a servile capacity, to receive his full instructions as to the medicines prescribed; the apothecary was ordered to attend their operations: and the time is not very remote when one of his duties was to hold the basin and the patient's head, while an emetic was producing its effects. The apothecaries not only submitted to this degradation, but actually boasted to the House of Lords of their utility in this respect, and made it their strongest argument to obtain a renewal of their act of exemption from parish and ward offices. They consented to follow in the footsteps of the physician, no doubt foreseeing that they would soon tread on his heels. They represented to the public, that being the compounders of physicians' prescriptions, they knew the composition; and, as they saw the patient with the physician, they had the opportunity of learning the symptoms for which that medicine was exhibited, as well as of witnessing its effects: that therefore it was matter of little importance whether the doctor or the apothecary was called in to attend the sick. The unwise policy of the physicians in expecting heavy fees, determined the balance of choice in favour of the apothecary: and the result was that the physicians soon had sufficient leisure to meditate on their want of timely prudence, and to devise a measure of retalliation. At first, they tried to write down the apothecaries; the press teemed with pamphlets, philippicks, squibs, puffs, poems, songs, and even plays. But this warfare, to the full as unwise as their former policy towards the apothecaries, only gave the latter an opportunity of showing the public, in print, how useful they were, how much they endured for being so, and how truly the virulence of the physicians might be considered as the measure of the services of the apothecaries to the public. Finding all these efforts useless, and perceiving that the apothecaries were beginning to educate themselves, and were gaining public confidence, the physicians began to think that it was high time to attempt to undo what they had done.

Accordingly, in 1639, about twenty-two years after the incorporation of the apothecaries, the College of Physicians represented to King Charles I., that the apothecaries were increasing prodigiously by the practice of each taking two or three apprentices to do the home business while their masters were out prescribing; that they had invaded the province of the physicians, and endangered the lives of the public. The King received this impeachment in council; proofs were tendered; the charges were declared to be proved; the judges were consulted, and they unanimously agreed to the necessity of reducing the number of the apothecaries. They were of opinion that the apothecaries "by making an ill use of their charter had virtually repealed it and destroyed all the acts of Parliament which had been made to secure life and health." The Attorney-General was, therefore, commanded by *quo warranto* to dissolve their charter; and after a year, occupied in vain with defensive pleadings on the part of the apothecaries before the council, the Lord President was directed to command the prosecution without delay. His Majesty then pronounced the dissolution by the following declaration: "That the excessive number of apothecaries is inconsistent with the safety of our royal person and family, and of all our subjects. The physicians of the College have demonstrated that the public may have the medicines sufficiently compounded for [the general diseases from not many of you placed at the proper distances in the city. When you shall fill all the streets you must starve, if the poor are not undone by you, and the wealthy pestered and killed by the numbers of the doses in almost all diseases. You will desert your labours in preparing the remedies; and, against the excellent provision of the laws, undertake the cures of diseases with the knavish artifices and impostures of your own prices for all your fraudulent

divisions. A great part of the physicians shall be compelled to sacrifice their patients to your necessity, and by the perfidious justification of your quackeries on the most severe diseases, betray their profession to you; and at last, by practising only on the diseases disordered and confused by you, shall never make the just observations of the natures and progress, and of the effects of their medicines. The College shall be broken by the most raging feuds and animosities, and the promotion of the knowledge of all the parts of the learned profession shall cease. Your company is, therefore, dissolved; the College is ordered to represent to this board how many of you may be tolerated, not to increase but with the enlargement of the city."

(To be continued.)

SHORT NOTES ON NICE.

By JAMES STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS, IRELAND; SURGEON TO JERVIS-STREET HOSPITAL; CONSULTING SURGEON TO THE COOMBE LYING-IN HOSPITAL; SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD, &c.

(Continued from page 467.)

THE following is the interesting description which was published of the old town of Nice by Tobias Smollett M.D., in 1765, introductory to a register of the weather[1] kept by him at Nice from November 1763 to March 1765 :—

"The town of Nice is situated in the bay of Antibes, latitude forty-three degrees, forty minutes north ; east longitude from London, seven degrees, twenty-five minutes, equidistant from Marseilles, Genoa, and Turin, that is about ninety English miles. The north wind blows over the maritime Alps, at the feet of which the town is situated ; the south from Cape Bona, on the coast of Barbary, sweeping the islands of Sardinia and Corsica in its passage ; the east from the Riviera of Genoa ; and the west from Provence.

"The town of Nice is wedged between a steep rock to the eastward, and the river Paglion, which washes the wall upon the west, and falls into the Mediterranean, within thirty yards of the corner bastion.

"This river is but a scanty stream, fed chiefly by the melting of the snow upon the mountains. It is sometimes swelled to a great depth, by sudden torrents ; but in the summer it is usually dry.

"The town of Nice is built of stone, and the streets are narrow. It is said to contain 12,000 inhabitants, in which case they must be much crowded, for the place is but small. There is a bridge of three arches over the Paglion, which is the entrance from the side of Provence. Nice is surrounded on this side by a wall and rampart of no strength ; on the other side it is commanded by a high rock, on which appear the ruins of an old castle, which was once deemed impregnable. It was taken, and dismantled by Mareschal Catinat, in the reign of Victor Amadeus, father to the present king of Sardinia. To the eastward of this rock is the harbour of Nice, in which there is not depth of water sufficient for ships of any burden. The hills begin to rise about a short mile from the north gate of the town. The Var falls into the sea about four miles to the westward ; and is fordable at the village of St. Laurent, which stands on the French side, near the mouth of the river. The space between the Var and Nice, is a succession of agreeable eminences, adorned with a great number of white houses, or cassines, surrounded by plantations of olives, vines, oranges, lemons, and citrons. The air of Nice is pure and penetrating, yet mild, generally dry, and elastic ; and the sky is remarkably clear and serene. The well water is mostly hard, but not unwholesome ; and there are some springs both in the town and neighbourhood, which are surprisingly cold, limpid, and agreeable."

I have been favoured by three physicians of high reputation, at present practising at Nice, viz., Drs. Pantaleone, Travis, and Trousdell, with letters containing their experience of Nice as a residence for invalids, which they have kindly permitted me to publish, and which I now do, believing that they will prove valuable to the profession.

Dr. Pantaleone's observations on Nice admit of being considered, *in a condensed form*, under two heads :—

1*st*. With respect to the class of patients who are benefitted by a residence at Nice.

2*ndly*. With regard to the numerous forms of diseases which are disserved by the climate of Nice.

Respecting the first, Dr. Pantaleone says :—"Patients labouring under tuberculosis, or chronic scrofulous consolidation of the lungs in their upper portions, cannot find any better climate than that of Nice. I have known a few undoubted cases of the disease which had been diagnosed by some of the first physicians in Europe, cured by a residence at Nice, without leaving any trace of the previous ailment, detectible by either auscultation or percussion. In other cases the consolidation remained stationary without any bad consequences, no change taking place, as I have seen, for four or five years spent at Nice, or suitable parts of France, or England ; these are indeed the most striking cases of real and permanent cures, the results of a residence at Nice. But if there is fever, or sub-acute inflammation present in such cases, then Nice is one of the worst possible places for such patients; under which circumstances, I think Méntone[1] answers better than either Cannes, or Nice ; but in cases of tuberculosis of the lung, where there is great irritability present, Rome is, according to my experience, a more suitable climate than any place I am acquainted with, provided the patient is not suffering under atonic dyspepsia.

"Old chronic catarrhs cannot find a better climate in Europe than Nice, the same may be said of chronic asthma ; but according to the special characteristics of these diseases, sometimes your department No. 1, sometimes No. 2, and in other cases No. 3 (which you so faithfully described in the "Notes on Nice," which you were taking whilst here), will prove most beneficial.

Chronic diseases of the liver do well at Nice.

Albuminuria is benefitted by the warm dry atmosphere of Nice.

"Amenorrhœa, as a general rule, readily yields to proper treatment at Nice, partly, perhaps, on account of the improvement imparted by a residence here to the general health, and partly perhaps owing to the tendency in the climate to diminish various forms of abdominal congestion.

"I have met with two cases of Lucocythimia at Nice—one was benefitted by the climate, but I lost sight of it ultimately. The second case is *perfectly cured*, all the hæmorrhages have disappeared, the spleen has returned to its normal size, the blood, on microscopic examination, shows no difference from its normal condition, and the patient has become from 156 lbs. in weight to 192 lbs.; his natural colour has returned, and his general health and strength are in every way excellent. I publish this case as it is the only one of the disease which, according to my knowledge, has been cured. The climate of Nice helped me much in my successful treatment of the foregoing case.

"Gouty and rheumatic patients are benefitted by the climate of Nice. Generally speaking, in gout, no fixed attacks of the disease are experienced here; and what is important to record is, that the disease is checked without any of the bad results of suppressed gout.

"Having thus given you an outline of the diseases which are benefitted by Nice, I shall next mention those affections which are not served by our climate, and which, therefore, ought *not* to be sent here. I shall, at the same time, make a few observations on the diseases which are produced, or born, at Nice.

"All inflammatory complaints, but more especially those

1 "The Miscellaneous Works of Tobias Smollett, M.D., by Robert Anderson, M.D., vol. v.," 1800.

1 Having paid a flying visit to Mentone, I am bound to say that I formed a very favourable opinion of its genial climate and sheltered aspect, and I have no hesitation in saying that both the public and medical profession are greatly indebted to Dr. Bennett (who was very attentive to me during my short visit to Mentone, and pointed out to me its numerous advantages) for having directed their attention to that sunny spot. Dr. Bennett's able and interesting work on Mentone ought to be in the hands of every medical practitioner.—J. S. H.

of the brain, are increased by the stimulating effects of the climate of Nice. In fact, no inflammatory affections of the brain or spinal marrow, are served by a residence at Nice, and the same observation holds good respecting patients who are liable to attacks of excitement of the brain. Chronic paralytic cases are, on the contrary, for obvious reasons, benefitted by Nice; in fact, cases in which there is debility without inflammation. I cannot better explain my views with respect to paralytic patients than to say that these cases of paralysis in which the stimulating springs of Wilbad or Gastein would be dangerous, ought *not* to come to Nice. Under contrary dispositions they will find Nice the best place of residence they can select.

"Cases of diarrhœa are frequently met here, and if not properly attended to, prove most obstinate, more especially if opium has been injudiciously had recourse to.

"Cases of bronchitis are frequently produced at Nice by the sudden changes of temperature from hot to cold, in those who imprudently expose themselves without taking proper precautions.

"Ordinary cases of fever are very rare at Nice, but cases of ague, when developed, are very obstinate.

"Exanthemata, when met with, are very mild, and they very seldom spread extensively from house to house, or grow prevalent, and this observation applies to every other form of contagious disease, and this is obviously due to the isolation of the houses, and prevalence of wind at Nice.

"Inflammatory affections are rare here, and seldom present themselves in very acute forms. In seven years' residence here, I have been obliged to use *general* depletion in only three cases of acute inflammation, whilst local depletion has, of course, been called for in many diseases.

"Scrofula is not rare amongst the natives of Nice, or Nizzards, but, generally speaking, it is a disease limited to children of the inferior classes in the old town, from the combined wants of good drainage,[1] fresh air, nourishing food, proper raiment, and cleanliness.

The following are Dr. Travis' observations on Nice, which I give in their entirety :—

Nice, 12th February, 1868.

My Dear Dr. Hughes,—At length I am at liberty to fulfil my promise of writing you a few lines on the subject of your inquiries when at Nice, although I have little to add to the remarks I made, in answer to your inquiries, when I had the pleasure of seeing you here.

I may commence by stating that in twenty-seven winters I have passed at Nice, we have never had so long or so severe a season of cold as the present one, the worst and most trying part of it having been during the time you were here, and the invalids have felt it proportionately.

Nice is, indeed, as I mentioned to you, unfavourable to a large proportion of persons suffering from affections of the chest, of whom a much smaller number are now sent to Nice than formerly. Where tubercular phthisis has advanced beyond the first stage, I have rarely seen any invalid improve at Nice, but chronic bronchitis, peripneumonia, notha or winter catarrh, with profuse expectoration, and even that most capricious malady *asthma* (in some forms), are all benefitted by a residence at Nice, and I have known many individuals who had a great facility for catching cold (as it is termed) become much less susceptible from a winter at Nice.

The part of Nice best suited to these cases, as you yourself must have observed, is on the land side, away from the sea, including Cimies (the site of the old Roman City), St. Etienne, Carabacel, and St. Barthelemi.

These districts are all considerably more sheltered than the town of Nice, and in consequence of the absence of wind, the temperature is somewhat higher; the air too is more moist—a great advantage in a climate where rain does not fall for many weeks together. The most sheltered part of the sea-shore is beyond the port, in the quarter called the Lazaret.

The peculiar property in the Nice air which seems so unfavourable to consumptive patients is also very trying to dyspepsia of an irritable character; whilst, on the contrary, in nervous dyspepsia and many chronic conditions of the asthenic class, the dry stimulating air of Nice is very advantageous.

Indeed it is in the broken down condition of health, after severe illnesses, &c., that the most surprising effects of this climate are visible, with scarcely any medical treatment whatever.

Loss of physical and mental energy from whatever cause seem gradually to disappear, and there is never a season at Nice that some remarkable instance of this kind does not present itself.

Nice is also remarkable for its favourable effect in rheumatic and gouty complaints, in neuralgia also, where the patient will take ordinary precautions in avoiding drafts and sudden changes of temperature.

On this latter point, as in all countries where the sun is powerful, and the air, from the proximity of snow-mountains, cold, too much stress cannot be laid on the danger of being out about sun-set, from the sudden abstraction of heat from the surface of the body by evaporation.

There is a peculiarity along this coast in the inability, which many persons experience, as to sleeping close to the sea, whilst a removal to a distance of only a few hundred yards will very frequently remove this difficulty altogether, this occurs so frequently as scarcely to be credible if not noted by an eye-witness.

I ought, perhaps, to mention that our finest months are usually November, December, January, and February, especially the two former, when the sky is frequently for many days together without a cloud. March, as in every other part of Europe, is a windy month, but on an average of twenty years, there are not more than ten or twelve days of wind between the 25th February and 10th of April of each year.

Intermittent and other fevers are of very rare occurrence at Nice, either among the natives or visitors.

The facility of reaching Nice of late by rail has been a snare to many invalids—inducing them to remain too late in England and other cold countries.

To secure the full advantage from his winter in the South, the invalid should be established in his quarters by the end of October.

I dare say I have omitted many things which you would have proposed to me, had you been at hand, but I think I have included everything of importance that could come within the scope of a letter. Should I not have done so, you have only to write to me, *any direct questions* which I will answer *seriatim* to the best of my power.—Believe me to remain, yours sincerely,

W. A. Travis, M.D.Edin., F.R.C.P.L.

Dr. Trousdell, L.R.C.S.G., writes to me as follows :—

"I would strongly recommend medical men in Great Britain to send all cases of albuminuria, whether associated or not with gouty diathesis, to Nice. According to my experience in such cases, relief is obtained very soon, indeed, after a residence here. The skin which before refused to act, as a general rule, now acts abundantly; and œdema of the extremities (should such be present) disappears in a very short time. The patient being able to live the greater part of the day in the open air and *sunshine*, rapidly regains his appetite and strength, and is able to take and enjoy long walks, instead of being shut up in his room as at home, with no other object in view than attending to, and keeping up a *good fire*. But at the same time the invalid must observe certain precautions, and not expose himself to currents of *cold air*, which are to be found in shady places; nor is he to remain out of doors until sunset, as the air suddenly be-

1 I regret to say that the sewage of Nice is in a very imperfect state; in fact, if I am rightly informed, there is no sewage properly so called, every house having a tank which has to be emptied from time to time, and the stench of some parts of modern Nice, especially on the Quai Massena is sometimes intolerable. I am told that the attention of the municipal authorities has been forcibly drawn by the medical men of Nice to the neglected condition of the sewage of the entire town, and it is to be hoped that ere long this serious drawback to the sanitary advantages of Nice will be rectified.—J. S. H.

comes cold, and a heavy dew falls a short time before the sun goes down. In albuminuria, as well as in all cases of a gouty or rheumatic tendency, a residence at Nice throughout the summer months would, in my opinion, confer more benefit than even during the winter months, as a continual free action of the skin is kept up, without any *depressing* effects from the heat of the climate; and at this season, in addition, an invalid is not subject to the chances of catching colds by sudden changes of temperature as in the winter and spring months; nor is he *debilitated* in any way by the *asserted* great heat of the climate.

"I have been induced to make these few remarks as to a summer's residence at Nice, as I know that it is generally believed by most, if not all of our winter visitors, that Nice is, or *must* be, a perfect *furnace* during the summer months; I am, however, in a position to say that such is not the case. Last summer, the thermometer stood at 84° in the shade at noon (except for a very short time, when it rose to 86°) for nearly three months, and so steady was the temperature during these months, that the thermometer registered the same heat each day at the corresponding hours; and every day from about nine A.M., a strong sea breeze set in, and blew uninterruptedly up to about five P.M. many days, causing such an amount of surf on the beach, that it was impossible for the bathers to enjoy their swim. In fact, an invalid may spend his entire day out in the open-air in summer as well as in winter; at mid-day he may saunter (or sit out) either on the shady side of the streets, or under the shelter of the beautiful trees, under which a person may walk almost from one end of Nice to the other without even seeing the sun. The sea-bathing at Nice, which is excellent, is prolonged to a late period in the year. And as for the genial nature of the climate in the mornings and afternoons, it is really more delightful than I can possibly find words to describe it in. Thunder-storms are not frequent during this season, and when they do occur are not severe; they are attended by heavy showers, which are very refreshing. I may add here, that although no rain falls for three or four months, except an occasional shower of this sort, that the country does not look dried up and burned as in England, after a few weeks dry weather in summer. To all this, there is an abundance of fruits of all kinds (marvellously cheap), flowers and vegetables, house-rent at an extremely low price; carriages, row-boats, and little yachts for hire, easily to be got, and at a moderate tariff — with many other advantages which are too numerous to mention in this short paper, but to which I would strongly call the attention of my medical brethren, when in any doubt as to a fit place to recommend a change of climate, during the summer, to any of their patients who may be affected with the diseases I have named above.

"To return to the winter season. Another class of disease for which I would recommend a residence at Nice is dyspepsia, in most of its forms, whether as a primary or secondary lesion, and especially that form of the disease brought before the Medico-Chirurgical Society by Dr. Fuller, attended with extreme langour, restlessness, flatulence, and acidity, with an excess of urea in the urine. In this complaint I have seen the greatest benefit, in fact a perfect cure, result from a winter's sojourn at Nice.

"Lastly, I would call attention to a class of people who though not, strictly speaking, 'invalids,' nevertheless are always ailing, and during the winter and spring months scarcely if ever breathe the open and pure air. Such people are generally in the decline of life; readily catch cold in the least exposure; are always 'wheezy' or rheumatic, and, as a rule, from the sedentary, shut-up lives they are obliged to lead, die years before their time. To such people and their medical advisers I would say, and earnestly entreat them, as soon as October sets in, set off at once for Nice for the winter months, where, by passing the best part of the day in the open air, they will gain a 'Renewal of Life,' and thereby add years to their existence. I could quote many such cases of prudent elderly people who yearly make Nice their winter residence, receiving as their reward the greatest of all blessings, health and longevity.

"One very great advantage which I consider Nice possesses for the invalids, or that last class of persons, viz., those who come here to 'cheat' the winter, is that it offers a great variety of amusements all the day long, and from its great extent and large population, especially in winter, increased as it is by people of all nations, that the invalid is not constantly meeting with other invalids, thereby reminding him perpetually of his misfortunes, and I have no doubt that the very gay and amusing scenes which constantly keep the mind away from thinking or brooding over the ills of the body, contribute in no small degree to the hygienic and restorative effects of this more than favoured spot of the South of France.

"Many people are deterred from coming to Nice on account of the great distance it is from England, but in these days distance is nothing. A few years ago it was a formidable journey to undertake, both as to time and expense. Now-a-days, the railways and steamers have done away with both.

"In fine, I may sum up these observations by saying that in the class of cases I have named, that the climate of Nice is the most powerful *restorative means* at our command."

(To be continued.)

NOTES ON ACNE ROSACEA.

By H. S. PURDON, M.D., L.R.C.P.Edin., L.R.C.S.I.,

PHYSICIAN BELFAST DISPENSARY FOR DISEASES OF THE SKIN, ASSISTANT-PHYSICIAN BELFAST CHARITABLE INFIRMARY AND INSTITUTION, ETC.

THE nose is the common seat of acne rosacea, the integument being of a deep violet colour, covered with elevations which slowly suppurate. The affected skin is thickened and infiltrated, and in chronic cases the alæ are pendulous, granulated, and liable to ulceration, in many instances the superficial veins are enlarged and varicose.

Mr. E. Wilson considers acne rosacea to be an eczematous affection, and Hebra states that "accumulated sebaceous matter often sets up an inflammation of the follicles, which would naturally be termed a folliculitis, but is generally called acne." This observation endorses the statement of Dr. Ross, who looks on acne rosacea as due to a determination of blood to the capillary vessels—a hyperæmia—which leads to inflammation of the sebaceous follicles, which pustulate, but do not mature readily.

Hardy considers acne to be a purely local disease, and, according to Mr. E. Wilson, "Gutta rosacea originates in debility, most frequently assimilative, next nutritive and sometimes nervous, is chronic in duration, and possess close sympathies with the digestive and reproductive organs."

In gutta rosacea, as well as the other forms of acne, the tongue is generally covered with a white, creamy fur, especially in the morning. When such is the case, the best treatment to commence with is the administration of the sulphates of iron, magnesia, and quinine given in infusion of calumba. This mixture will have the effect of cleaning the tongue, gives tone to the stomach, acts as a mild aperient, and prepares the way for the administration of arsenic. I agree with Mr. Milton that "lowering remedies" are injurious in acne rosacea, which is a disease due to debility, the subjects of it having usually impaired appetites and weakened digestion. Tonic remedies are indicated, and nitro-hydrochloric acid in decoction of cinchona has been recommended, especially as it acts on the liver, an organ generally at fault. The internal use of cod liver oil is also very beneficial. But to cure this disease permanently it is generally necessary to put the patient under a course of arsenic, and which may be commenced as soon as the tongue is clean and the liver in proper working order, the preparation that I usually prescribe is the liquor sodæ arseniatis, given in doses of ten drops thrice

daily after food. In some cases where the patients are what is commonly called "bilious," it is necessary to order taraxicum, and the following is a good form for its administration, it also acts as a diuretic :—

℞ Decoct. scoparii, ad ℥viii.
Spt. etheri nitrosi, ℥ii.
Succi taraxici ℥i.

Sig., a tablespoonful three times in the day.

For flatulence, a common complaint amongst these patients, the efficacy of the compound tincture of cardamom is well-known, or the following, if the appetite is impaired and depression of spirits complained of :—

℞ Tinct. valerian ammoniat, ℥iss.
Quiniæ sulphat, gr. xx.

Sig., a teaspoonful three times a day in a wineglassful of water.

The nitro-hydrochloric acid foot-bath is also a valuable agent.

In the treatment of acne rosacea by external applications, the hypochloride of sulphur ointment, one drachm to the ounce, is a very valuable application, and stands first on the list in importance, being superior to the iodide of sulphur. The following ointment I have used in several cases with the best results :—

℞ Hydrargyri iodi virid, gr. x.
Sulphuris, ℥i.
Adeps, ℥i.

A little oil of bergamot or bitter almonds may be added to cover the smell of the sulphur. Individuals, the subject of acne after exposure to excess of heat, as over a large fire, are frequently troubled by an increase of inflammation of an acute nature in the affected part. In such cases the constant application of the "glycerole of starch" for a few days is of benefit, and in place of soap the following may be used :—Take of glycerine, by weight, five parts, yolk of egg four parts, mix; this application, which has lately been recommended in the *Philadelphia Journal of Pharmacy*, is of a very soothing nature, and is of the consistence of honey, a little of which can be applied before exposure to cold, heat, &c.

In inveterate cases, painting the part affected with the solution of the terchloride of antimony for a few seconds, and afterwards applying a sponge soaked in a solution of carbonate of soda, is of benefit, especially when the integument is much thickened ; a poultice of rice-flour being applied at night, or Dr. Ross's method of treatment may be adopted instead, which consists in puncturing each separate tubercle, and inserting an ordinary capillary vaccination tube, containing a drop or two of nitric acid. This excites inflammation of the follicles, and thus occasions obliteration. I can strongly recommend this method of treatment as I have found it successful in many cases where ointments and lotions had proved useless.

It is a common custom to prescribe the bichloride of mercury in the form of a lotion in the treatment of acne ; now, if this remedy be persevered in for any length of time, it occasions a scaliness and hardness of the cuticle which is very annoying. Borax has quite the contrary effect ; it is equally efficacious, and can be prescribed in conjunction with glycerine and tincture of benzoin.

THE TREATMENT OF HÆMORRHOIDS.

By J. MULVANY, M.D., L.R.C.S.Ed., Etc.,
ASSISTANT-SURGEON ROYAL NAVY.

FEW diseases occasion more distressing sensations than internal hæmorrhoids ; few are productive of more corporal debility, or mental disquietude—irksome to the patient, hitherto contumaceous to the physician, they have long afforded an arena for the exercise of surgical skill : the number of remedial agents which from time to time have been recommended for their removal, affording at the sametime ample evidence of the fecundity of the inventive genius of the faculty, and the intractability of the affection. Blisters, the actual cautery, persulphas, and perchloras ferri, the knife, the ligature, separately and conjointly, have been warmly extolled. Latterly, to the application of nitric acid, first, I believe, used in Dublin, is unanimously conceded the largest meed of laudation. But however efficacious such an application may be, the nervous, debilitated, chronic sufferers, who form the majority of those seeking surgical aid in those cases, will not submit without repugnance to the employment of so potent an agent. A simplification of the mode of treatment, sans the knife, nitric acid, *et hoc genus omne*, occurred to me, might be suggested by a careful consideration of the anatomy during health, and the pathological condition during varix of that portion of the alimentary canal, which may be termed the hæmorrhoidal region, extending from the anus to a line or two above the internal sphincter. Superiorly, this is lined by mucous membrane, by no means intimately adherent to the subjacent tissue ; inferiorly its character changes, and becomes muco-cutaneous ; whilst, in the middle third, we find the cutaneous element prolonged into triangular vertical linguettæ, named by Morgagni, the columns of the anus. At their junction, *en bas*, they form a number of valvular folds more or less elevated, with their concavities directed upwards, which are deserving of attention. Next to the mucous membrane is the cellular coat in which the hæmorrhoidal vessels ramify ; more externally are the sphincters, next a few pale muscular fibres, prolonged from the longitudinal bands, imagined by Sappey to assist in dilating the anus, and which probably serve by their contraction to assist the movement of the venous blood through the superior hæmorrhoidal vein. Next in order we have the levator ani, and then a soft yielding, adipose cushion filling up the ischiorectal fossa. The vascular supply, derived from the inferior mesenteric, internal iliac, and pudic arteries, is returned by two sets of veins into the systemic and portal systems. By the inferior hæmorrhoidal, the blood collected from the anus and external sphincter, is poured into the internal iliac. This vein differs from the superior in its comparatively short course, and its being provided with valves. The superior hæmorrhoidal, commencing in an intricate network, much more extensive than that of the inferior, situated beneath the semilunar valves of Morgagni, ascends into the abdomen as a tributary of the portal.

Thus we see that this vein is pre-eminently disposed to varix, from a variety of causes, viz. :—its length, rendering it so liable to pressure ; its opening into the splenic, almost at right angles behind the pancreas ; its blood having to pass through the liver ; its being unprovided with valves ; the tendency of the Morgagnian festoons to obstruct the passage of hardened fæces and favour their impaction ; their relation to the venous plexus, whereby this will probably be dragged down, when prolapsus of the mucous membrane occurs from the pressure of impacted fæces ; straining at stool, &c. ; the laxity of the mucous attachment ; the yielding walls of the canal and constitution of the muscular planes during defecation, contribute towards the same result.

The immediate causes of hæmorrhoids are such as lessen the *vis a tergo*, or impede the venous current, *a fronte*, the former constituted by general muscular relaxation, and diminished contractility of the hæmorrhoidal arterial coats, as frequently results from residing in the West Indian climate. The latter, by mechanical impedimenta, removable or irremovable. Of the removable, constipation is by far the most frequently exciting cause, for, when habitual, the muscular walls of the rectum gradually lose their tone and sensibility, and become more or less paralysed by the excentric pressure of the contained fæces, dilatation succeeds, and the ascending column of blood from the rectum thus pressed on, suffers retardation, is thrown back on the hæmorrhoidal plexus, and varix ensues.

In warm climates, in consequence of the rarefaction of the atmosphere, the liver is called into increased activity, to supplement the lungs, and the blood is depurated by the increased elimination of its biliary elements. Thus a

tendency to relaxation of the bowels, or diarrhœas, exists at the same time; owing to the debilitating effects of caloric, relaxation of the muscular tunic of the hæmorrhoidal arteries takes place with partial paresis of their vasomotor nerves, as may be inferred from the dilated condition of the corresponding capillaries; hence an unusual afflux of blood to the anal region takes place, which, if further augmented by hepatic torpor, or by the constriction of the muscular planes surrounding the gut during a violent diarrhœa, such as is likely to occur in the crisis of a bilious remittent, cannot be directly propelled by the weakened heart through the portal system, and if not finding a ready outlet through the systemic veins, will, necessarily, press with increased gravitic force on the hæmorrhoidal venous plexus and capillaries, and these yielding, become varicose, and pushing before them the lax mucous membrane and Morgagnian structures, descend as a hæmorrhoidal tumour into the bowel, where, exciting spasmodic contraction of the sphincter, and inducing irritation of the bladder, it becomes the head and front of a series of uneasy sensations, which render defecation a martyrdom, produce constipation, and thereby *emperran el mal.*

For a somewhat similar reason the disease is frequently met with amongst stokers, the heat of the fires producing muscular relaxation, and their stooping and holding the breath, with the diaphragm consequently fixed, during the act of shovelling, increasing the amount of blood in the abdominal veins.

The internal pile, so produced, is broad and vascular, has a tendency to abrasion, bleeding, and inflammation. It may be regarded as the true internal pile, the change of shape, consistence, appearance, or character which it is apt to undergo being the effects of subsequent inflammation and effusion of lymph or blood; it differs from the external in being composed of capillaries, veins, and relaxed Morgagnian columns, in denoting a greater amount of embarrassment in the hæmorrhoidal circulation, and in the external, as well as what has been called the intermediate pile, being the result of a minor degree of retardation from pressure, or causes purely local, such as heat, cold, irritation from various sources, &c.

For the purposes of treatment, hæmorrhoids may be classed under three heads—1st, those requiring constitutional treatment alone; 2nd, those for which topical applications suffice; and, 3rd, those for which a combination of topical and constitutional remedies are requisite. Under the first head come the true internal pile, and that in which the capillary element is less prominent. Under the second are the external and intermediate piles, whilst the third embraces the cellular, erectile, fleshy, warty, &c., internal piles.

The rationale of treatment is extremely simple, and consists in the adaptation of remedial agents to correct the pathological conditions on which they depend—in other words, to remove constipation, restore peristaltic action, give tone to the paralysed muscular tissue of the great intestine, constringe the dilated hæmorrhoidal capillaries by increasing the contractility of the middle coats of their supplying arteries, and thus enable the veins to resume their normal degree of rectitude.

In belladonna we possess an agent capable of supplying by its physiological action all these desiderata. Because, acting through the intestinal branches of the solar plexus, it will increase peristaltic action, and restore tone to the paralysed muscular fibres of the colon and rectum, by which means the bowel may be unloaded and kept in a state of solution, and pressure be thus taken off the hæmorrhoidal plexus and semicircular festoons, a desideratum which may be much accelerated by the previous administration of a dose of castor oil, to clear out the bowel and facilitate absorption.

Again, by acting on the vasomotor nerves of the hæmorrhoidal arteries it will promote the contractility of their muscular tunics, lessen the supply of blood to the trajet-anal, and thereby check bleeding, and, at the same time, diminish the size of, and ultimately remove, hæmorrhoidal tumours of the first class.

On these data, I was led to the employment of belladonna in those cases 18 months ago, and have every reason to be satisfied with it. In November, 1866, a relative of mine, Mr. M——, came under my care for bleeding internal piles of two years' duration, brought on by residence in the tropics, and a severe diarrhœa. The hæmorrhoid was large, vascular, very hot, protruded, and bled during defacation; gave rise to much vesical irritation; a constant feeling of fulness in the rectum; constipation; frequent desire to go to stool; much mental uneasiness; emaciation, and general debility. His sufferings were great, so great that they finally overcame a constitutional aversion which he entertained against all surgical operations; and he submitted to have anything done to give him relief. Having once induced an epileptiform fit in a much stronger patient by touching his chancre with nitric acid I determined to reserve this as a *dernier ressort*, and having cleared out his bowels with a dose of castor oil, I prescribed the fluid extract of belladonna for him in ℥ii. ss. doses, every four hours, and ordered a lavement of cold water, *bis die.* In two days the bleeding had quite ceased, and in ten days the hæmorrhoid had entirely disappeared, and has not returned since, though the laxity of mucous membrane still continues, and causes it to prolapse slightly at stool.

To give a number of similar cases with like results would be a useless repetition. I may, however, mention that I have used it with perfect success in the case of a lady eight and a-half months pregnant; believing that the gravid uterus acted indirectly by pressure on the fæcal tract, rather than on the veins, and that the consequent accumulation of fæces was the obstructing power to the free return of the venous blood, and knowing that belladonna is extensively used in America during the last days of gestation for dilating the os uteri, I, as she was then suffering a good deal from the bleeding internal pile, put her on two minim doses of the fluid ext. belladonna, *ter die.* A cure was effected in less than a week. I, however, continued the belladonna to the period of her accouchement, and I certainly think it facilitated her labour.

For the external pile the grease which runs from the hot bearings and eccentrics in the engine-room of a steamer when under steam, will be found an unfailing remedy. Chemically considered, it is rather complex in composition, and may be presumed to be a combination of the fatty acids and oil, used as lubricating materials, with the oxides of the more oxidisable metals exposed to friction. By the bearings are meant the fixtures in which the shaft works. They are made of brass and lined, to a certain extent, with a patent metal, composed of copper, tin, and antimony, or of zinc, lead, antimony, and platinum. The shaft is formed of wrought iron, and the brass is composed of copper, zinc, and tin. The bulk, however, of the metals oxidised, judging from a rough analysis I made, is formed of the copper and lead. There was hardly a trace of zinc, and none at all of the others found in a drachm of the ointment.

As the liquified grease drips from the bearings, it is caught in a "save-all," and on cooling is fit for use. It should be mixed with one-eighth its bulk of lard. It then forms an ointment of a pale blue colour, the efficacy of which is so well-known to the stokers that they treat, *sub rosa*, nearly all the cases of piles that occur on board ship. A chief stoker of my acquaintance told me he had treated successfully over fifty patients. He used it indiscriminately for all kinds of piles. From my own experience, I can only vouch for its utility in cases of the external or intermediate varieties; but lately I treated a stoker with it whose anus was festooned with mariscœ, without putting him on the list or getting him excused from duty. He was rid of his garnitures in about a fortnight. It proved equally efficacious in the case of a jockey from the United States, who suffered from the internal, fleshy, and external piles during a number of years, and who had to resign his occupation in consequence. It is needless to say this man had numberless remedies recommended, but *cui bono?* His

occupation was gone, and could not be pursued until the ointment gave their *congé* to his unwelcome guests.

For the varieties of internal hæmorrhoids which come under the third heading, the castor-oil and belladonna, administered by the mouth, and the ointment applied locally, will usually suffice. How the ointment acts I can only conjecture, but can recommend it with confidence as safe, efficacious, and productive of but very little pain. It will, I think, be generally found that if nature dispenses afflictions to the human race with her left hand, she showers their panacea on us with her right; and if she sends sickness and disease in our midst, she also places their remedies within our reach, and leaves us to find them. To the Bolivians, for their various calenturas, she has given the Calisaya. If the bothriocephali find a commodious habitat in the dura ilia of the vassals of Theodorous, or perhaps in those of his sable majesty himself, has not nature drawn up a process of ejectment in the flowers of the Brayera Anthelmintica, which will not endanger the life of a bailiff to serve?

Do not the natives of the West Coast of Africa, when suffering from dysentery, find its specific in the fruit of the banana, prepared *secundum artem*, and found growing in the greatest profusion? and could she be less bountiful to stokers? No; if she permits the heat of the stokehold to festoon the anus of the stoker, she also prepares in an impromptu laboratory, in which the shaft and bearings, converted into a pestle and mortar, rub up the lubricating materials, and by means of heat, friction, and the atmosphere, produce an unguent calculated to remove his questionable decorations—one which, to use the language of an enthusiastic stoker whom it recently quit of such appendages, "is worth its weight in gold!"

Hospital Reports.

RICHMOND SURGICAL HOSPITAL.

Cases under the care of Mr. STOKES.

(Reported by Mr. JAMES ROSS.)

ŒDEMA OF THE GLOTTIS, IN A CHILD ÆT. THREE YEARS, FROM THE INHALATION OF STEAM: TRACHEOTOMY: RECOVERY.

THE following case is one of very considerable surgical interest, and illustrates, in a remarkable manner, the great practical value of the early performance of tracheotomy in certain cases of œdema of the glottis.

Ann Fullam, æt. three years, was admitted into the Richmond Hospital, on Tuesday evening the 19th ult., suffering from very great dyspnœa. Her mother stated that at five o'clock in the evening, the child attempted to take a drink from a kettle in which there was a quantity of boiling water. Nothing occurred in consequence of this to attract attention, until after the lapse of about two hours, when the breathing becoming short, quick, and stridulous, she was brought to Hospital. The following note was taken on the patient's admission:—"The lips were found to have been scalded, and there was a mark down the chin as if produced by a stream of boiling water. The soft palate was whitish, but the tongue was not burned. There was great dyspnœa, with considerable stridor, and a crowing noise resembling that in croup when she cried. The face was not much congested, but had a glazed, red, shining appearance. She could scarcely speak, uttering now and then a few syllables which were hoarse and rough."

The case was seen by Mr. Stokes shortly after 10 P.M., and notwithstanding the prompt measures which were had recourse to in order to relieve the dyspnœa, consisting of hot fomentations, poultices to the throat, local depletion, and the active administration of antimonials and mercury internally, the symptoms, as the night advanced, grew worse.

The dyspnœa, which came on in paroxysms of great intensity, became much aggravated, being more frequent and more violent, so that at times the patient was in imminent danger of suffocation. After midnight the symptoms became so alarming, that Mr. Stokes determined that tracheotomy was the only resource left in order to save the patient's life. The operation was accordingly performed above the isthmus of the thyroid, and was greatly facilitated by the tracheotomy hook of Langenbeck. The tube which was introduced was of a size fully adapted for an adult, and to this circumstance Mr. Stokes attributes largely the success of the operation.

On the completion of the operation immediate relief ensued, and the child slept soundly the whole night, the tube being occasionally cleared of mucus by means of a feather or a bent probe, with a little French wadding tied on it.

May 20.—Progressing very favourably; does not suffer any inconvenience from the tube; is very drowsy, and sleeps a great deal. In order to arouse her from what appeared a sort of semi-comatose condition, we administered a small quantity of green-tea, which was suggested by Mr. Adams. It had the desired effect. She took also plenty of nourishment, consisting of chicken-broth, egg-flip, wine, &c. The inner tube only required to be taken out once to be cleaned.

21st.—She slept well during the night. The tube required to be cleaned once, and during the day twice. The mucus is very tenacious, and neither a feather nor a probe armed with lint has any effect in bringing it up. Sometimes cleaning the inner tube seems to have no effect in giving relief, the mucus in the trachea being driven up to the outer tube, and is only got rid of by coughing. In the evening there was a slight attack of vomiting, which relieved her greatly.

22nd.—The child sat up this morning. Does not suffer apparently from any inconvenience in wearing the tube. The bowels were well moved.

23rd.—The tube was taken out this morning, but the glottis not being free enough for the child to breathe through, the tube was replaced. The child is cheerful and lively, and eats heartily.

24th.—The tube was taken out to-day, and as it was found she could breathe slightly through the mouth, the tube was left out. Large quantities of viscid mucus are frequently expelled through the wound.

25th.—Patient breathes much more freely through the mouth to-day, but cannot yet speak. Small doses of carb. ammoniæ in syrup of orange flowers were administered.

28th.—Patient attempting to speak. Wound in the trachea granulating and closing quickly.

29th.—Articulation much more distinct. Child very anxious to get up.

30th.—The opening in the trachea is now so small as to be scarcely perceptible. Patient speaks distinctly. Appetite is excellent. Patient is cheerful and happy, and respiration perfectly natural.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief Notes by Dr. TONGE.)

ALCOHOLIC POISONING.—W. B., æt. 39, chimney-sweep. Admitted December 25; discharged January 2; in hospital 8 days. *Recovery.* Drank half a bottle of gin shortly before admission. Then completely comatose; blue in the face; pulse very slow; breathing stertorous. Bronchitis afterwards.

Stomach Pump. Cold affusion. Wet towelling. Galvanism. Afterwards carbonate of ammonia, chloric ether, squills and senega.

HYDATIDS OF LIVER AND LUNG.—John W., æt. 19, mattress-stuffer. Admitted May 30; discharged August 31; in hospital 92 days. *Relieved.* Readmitted October 17. *Died* on November 14; in hospital 28 days. Subject to cough for some time; liver enlarged 1 month; cough worse 2 days. On admission, much greenish expectoration;

dulness and diminished vocal vibration below right scapular angle; breathing feeble at right base, elsewhere harsh; pulse 80; respiration 32; liver nearly down to umbilicus; 9 days later watery sputum, half-pint; 11 days later 4 pints, greenish brown expectoration; 12 days later expectoration yellow and fluid; 1 week later, a pint of bitter yolk of egg coloured sputum expectorated. After this the pain and expectoration became less, and the liver receded to 1 in below the margin of the ribs. Went to Seaford when discharged. On readmission breath shorter, pain worse; much tenderness in right lateral region; expectorates about 1 pint of yolk of egg coloured, bitter, sputum daily. Physical signs as before, but good breathing over right back except at base; liver larger. On November 13, sudden severe abdominal pain; cold sweats; diarrhœa; thready pulse; death on 14th.

P.-M.—A large abscess between liver and gall-bladder had burst into peritoneum, which contained much pus and recent lymph. In lower lobe of right lung was a large, irregular cavity, containing many yellow shrivelled hydatids, and communicating by an aperture in the diaphragm with a shrunken cyst in right lobe of liver. Lung, diaphragm, and liver were here all adherent. The right lobe of the liver was much smaller than the left lobe; puckered and fibrous on its surface, and some portions of it partly softened. There were seven or eight small gall stones in the gall bladder.

Dilute hydrochloric acid; liquor conchonæ and chloric ether. On November 1, henbane and aromatic spts. of ammonia; cod-liver oil; morphia.

Gout.—W. W., æt. 54, whitesmith. Admitted June 28; discharged July 25; in hospital 27 days. *Recovery.* No family history of gout. First attack 20 years ago in metac-phalangeal joint of right index-finger; frequent attacks since. Previously ill, 3 weeks. Right index-finger, right ankle and knee, and left knee affected successively. Tongue slightly furred; pulse 68; free from pain on 39th day. Fresh attack in left great toe 3 days later.

Bicarbonate and nitrate of potass (7 days). Then iodide of potassium and liquor cinchonæ; aperients.

Gout.—W. W., æt. 54, whitesmith. Admitted June 28; discharged July 25; in hospital 27 days. *Recovery.* After discharge on June 22, remained well for 6 days; then pain under left clavicle and pain and tenderness of knees, ankles, and right hand. Dyspnœa; dry cough; pulse 102; respiration 36. Chest sounds normal.

Bicarbonate of potass, carbonate of magnesia, and colchicum (9 days). Then same with liquor cinchonæ; alkaline lotion; aperients.

Gout.—G. P., æt. 44, paperhanger. Admitted Sept. 19, discharged Nov. 23; in hospital 65 days. *Recovery.* First attack 15 years ago in left great toe; second, 5 years later; third, a few months afterwards; since then has had about two attacks yearly. Previously ill, 1 day. Right hip and left hand, left ankle and hip affected; finger joints of right hand enlarged; free from pain on tenth day; twelve days later return of pain in left ankle; right wrist and fingers, left arm and right ankle afterwards attacked.

Bicarbonate of potass, and liquor ammonia acetatis, opium, liquor cinchonæ, chloric ether, and bicarbonate of potass; warm and alkaline baths; aperients.

Acute Rheumatism.—Elizabeth M'C., æt. 31, artificial flower-maker; admitted May 20, discharged June 25; in hospital 36 days. *Recovery.* First attack; previously ill 8 weeks. Had got wet shortly before. Left ankle, knee and hip, successively painful and swollen; free sweating. On admission joints painful, no swelling; systolic bruit at heart's apex; pulse 80; tongue white.

Bicarbonate and nitrate of potass. Then bicarbonate of potass, and iodide of potassium; Dover's powder; aperients.

Acute Rheumatism.—Jane C., æt. 23, servant. Admitted May 5; discharged July 2, in hospital 58 days. *Recovery.* First attack. Previously ill 5 days. Right knee, left knee, ankles, and left shoulder affected successively; slight sweating; tongue furred; faint systolic bruit at apex; pain about heart on 7th day; on 8th day pericardial friction sound; on 15th day præcordial dulness extends 1½ inches above nipple; on 24th day præcordial dulness normal; on 25th day dulness and feeble breathing over right base behind; dulness and bronchial breathing over lower half of right lung behind on 27th day; free from pain in joints on 28th day; respiratory sounds normal on 23rd day. Systolic bruit persistent.

Aromatic spts. of ammonia and bicarbonate of potass (11 days); same with chloric ether (8 days). Afterwards aromatic spts. of ammonia, chloric ether, liquor cinchonæ, and hydrocyanic acid. Aperients. Brandy, 6 oz.

Acute Rheumatism.—S. W., æt. 15, housemaid. Admitted March 8, discharged April 6; in hospital 29 days. *Recovery.* First attack (?). Chorea twice 4 years and 3 years ago. Three months ago præcordial pain and palpitation (2 days), then pain and swelling of joints, on and off till now. Previously ill 14 days. Commenced with præcordial pain, seven days later joints of right side affected. On admission, joints of right side tender and painful, not swollen; free sweating; pulse 90; much præcordial tenderness; systolic bruit loudest at heart's apex; slight pericardial friction sound at base; finally free from pain in joints and præcordia on 23rd day, but inaudible after 27th day; systolic bruit persistent.

Bicarbonate of potass and bark (11 days), aromatic spts. of ammonia, liq. cinchonæ, and chloric ether (10 days); then quinine and iron. Aperients.

Acute Rheumatism. — H. C., æt. 23, bricklayer's labourer. Admitted November 30; discharged December 21; in hospital 21 days. *Recovery.* First attack; flying pains about joints 2 months. Previously ill, 8 days. Right ankle and knee, left knee and ankle, hips, shoulders, elbows, and wrists, affected successively. On admission, knees, hips, and right shoulder painful; tongue furred; pulse 120; respiration 28; free sweating; highest temperature, 102·5° F. Free from pain on 21st day. Heart unaffected.

Bicarbonate of potass, aromatic spts. of ammonia, and chloric ether. On 17th day, liquor cinchonæ *vice* pot. bicarb. (9 days); then dilute muriatic acid, quinine, and quassia; Dover's powder o.n. Aperients. Brandy, to 12 oz.

Acute Rheumatism.—A. M., æt. 29, charwoman. Admitted December 24; discharged February 20; in hospital 58 days. *Recovery.* First attack. Previously ill, 2 days. In hands, wrists, knees, shoulders, and elbows successively; loss of appetite; weakness; tongue furred; profuse sweating; pulse 100; respiration 28; free from pain on 25th day; slight return of pain in knees on 42nd day. Heart unaffected.

Bicarbonate and nitrate on potass, and quinine and opium. After 25th day, dilute muriatic acid, chloric ether and bark; opiates at night. Brandy 6 oz.

Sub-acute Rheumatism.—Lucy L., æt. 36, cook. Admitted November 13; discharged December 10; in hospital 27 days. *Recovery.* First attack. Previously ill, 5 days. Right ankle and knee, arm-joints, and left leg affected intense; free sweating. On 10th day, free from pain; pulse 120; tongue nearly clean; systolic friction sound at heart's base (2 days).

Bicarbonate of potass, aromatic spts. of ammonia, chloric ether, and liq. ammon. acetatis (12 days); then aromatic spts. ammonia, chloric ether and bark. Calomel and castor-oil on admission.

Acute Rheumatism.—Ann C., æt. 48. Admitted Nov. 17; discharged December 10; in hospital 23 days. *Recovery.* First attack 20 years ago; shortness of breath on exertion; and occasional pain; palpitation and dropsy of legs 1 year; has spat blood. Previously ill, 3 months; right ankle, knee, and hip, right shoulder, left hand and elbow, right hand and elbow and joints of left leg affected successively; free sweating. On admission, pallid, left elbow, shoulder, and knee stiff; pain in back and in lower part of chest; pulse 80; systolic bruit at heart's apex; tongue furred.

Bicarbonate of potass, chloric ether, and aromatic spts. of ammonia.

Acute Rheumatism.—T. K., æt. 21, footman. Admitted May 19; discharged July 11; in hospital 53 days. *Recovery.* Second attack; first 10 years ago. Previously ill, 1 week. Left ankle, right ankle, left knee, right knee, left elbow, right elbow, left hand, and hips affected successively. Much sweating. Slight yellowish fur on tongue. Pain at heart's apex; first sound prolonged. Pulse 76. Finally free from pain on 32nd day.

Bicarbonate and nitrate of potass. Then same, with liquor cinchonæ. Dover's powder. Aperients.

Acute Rheumatism.—T. W., æt. 23, labourer. Admitted Sept. 14; discharged Sept. 30; in hospital 16 days. *Recovery.* Third attack; the first 8 years ago. Shortness of breath and palpitation on exertion 2 years. Previously ill, 7 days. Commenced in ankles. On admission, knees painful and swollen; heart's dulness increased; sounds feeble; sibilus and coarse crepitation over lungs.

Bicarbonate and nitrate of potass (7 days), iron and gentian (2 days); then quinine and dilute sulphuric acid. Aperients.

Acute Rheumatism.—Francis A., æt. 17, servant. Admitted July 14; discharged July 25; in hospital 11 days. *Recovery.* Fourth attack; third 11 months ago. Previously ill, 14 days. Left ankle and knee, right ankle and knee, shoulders and elbows, affected successively. On admission, tongue furred, left knee swollen, appetite bad. Pulse 96. Old systolic bruit at heart's apex. Free from pain on 19th day.

Bicarbonate of potass and aromatic spts. of ammonia.

Acute Rheumatism.—J. L., æt. 75, labourer. Admitted Nov. 25; discharged Dec. 12; in hospital 17 days. *Recovery.* Previously ill, 21 days. Right elbow, neck, hips, and knees affected successively. On 25th day right elbow and left side of neck painful. Free sweating. Tongue thickly coated. Pulse 88. Free from pain on 31st day.

Bicarbonate of potass and liquor cinchonæ, Dover's powder o.n. Brandy 4 oz.

(To be continued.)

Literature.

DISEASES OF WOMEN.

Of the several branches of the healing art, not one is more important than that devoted to diseases of women. The general practitioner is daily called upon to treat such diseases, and as principles have lately been overturned and others more or less firmly established in their places, there are many able men who will be glad to read up the present state of opinion respecting them. To all such we commend Dr. Hewitt's new edition[1] as a guide well worthy of their attentive study. The former edition of this work consisted of the substance of a course of lectures at St. Mary's Hospital, and at once placed the author in a conspicuous position amongst London teachers. The new edition differs very much from the last, and will, we are persuaded, add to Dr. Graily Hewitt's reputation.

We find not only large additions, but a more careful and systematic arrangement of materials, which will aid both student and practitioner.

There is a clinical air about the volume which will be highly prized, besides which we notice a candour in stating opinions that is, unfortunately, too rare with accoucheurs, who as a body have monopolised too much of professional squabbles, and as a result acquired an opinionated mode of expressing themselves which we do not find in this book.

The first part of the volume is occupied with diagnosis, and we doubt not that this will be the most studied, for upon correct diagnosis all accurate knowledge of disease depends, and in this particular class of maladies more faults are made in diagnosis than in treatment—at least by those practitioners who are not pure specialists. To the student and young general practitioner diagnosis is everything. The principles of treatment are easily comprehended, and are not half so likely to be forgotten as the details on which diagnosis depends.

The first section of diagnosis is a summary, in nine chapters, of the data obtained without physical examination. Then come 16 chapters on data to be gained by physical examination of, the external generative organs, the orifice and canal of the vagina, tumours felt through the walls of the vagina, the uterus (by the toucher, sound, and speculum), the abdomen and the breasts.

Here is scope enough for the most patient clinical teacher, and far too much for criticism in the brief space allotted by the editor to a notice of this work.

We will, however, delay a moment to express surprise that the author prefers the bivalve speculum *in all cases*, and thinks so little of the commonly-used round instrument that he dismisses it without a word, as unworthy of notice. We confess ourselves sufficiently old-fashioned to hesitate to accept this dictum, and so long as the round speculum remains the most commonly-used instrument by all classes of practitioners, we think it deserves a little more notice. We know that each operator of experience is at liberty to please himself. Personally we are indifferent what we use; we think it is a "poor workman who finds fault with his tools," as the proverb has it, and we use the duck-bill as often as anything for ordinary examinations. Nevertheless the ordinary round speculum is so universally used that we think the student should be instructed in its employment. This is a small thing to take exception to, perhaps. But then, our doing so shows how excellent as a whole is the work before us.

The second part of Dr. Hewitt's treatise is devoted to pathology and treatment, and we are glad to find that this edition is considerably richer than the former in pathology.

The treatment is, as might be expected, described in an orthodox manner, and may therefore be safely accepted as a guide. We must really say no more in favour of the work, lest we be thought too partial, and we shall venture to mention one point on which the author seems reserved, though perhaps this arises from his evident desire to do justice to all. We allude to the operation of incising the cervix, which has been practised so much of late, and too frequently with disastrous results. Our reading of Dr. Hewitt inspires us with the feeling that he distrusts it in the majority of cases—as we do. We have known it practised in cases which have excited our indignation beyond anything in modern obstetrics, and that is saying a good deal. We should therefore have been glad had the author spoken in unequivocal terms respecting the conduct of the inferior imitators of Marion Sims, and told how seldom such a proceeding can be justifiable.

Our notice would be incomplete without reference to the illustrations, which are in the highest style of art. More than sixty of these, we are told in the preface, are original. The great portion of these are planned representations of cases, drawn in outline, in the first instance, by the author. These outlines have been reduced by the camera, and drawn by Mr. Bagg, whose name alone is a guarantee of their merits. Altogether the volume is one of the handsomest of the season, and stands in need of no recommendation from the critic. Its success is certain.

1 The Diagnosis, Pathology, and Treatment of Diseases of Women, including the Diagnosis of Pregnancy. By Graily Hewitt, M.D., &c. 2nd edition. London: Longmans and Co. 1868.

SCIENCE AND PRACTICE OF MEDICINE.

The man who undertakes to write in these latter days a complete work on medical practice, sets himself an encyclopædic task, and one, moreover, that is little likely to be appreciated. The student or junior practitioner, indeed, if he find the work clear and concise in expression, complete in its scope, full of information in a condensed form, and withal, not too abounding in disputation, will feel his obligations to the author, and cherish a life-long regard for the well-thumbed guide, giving it a place of honour on his shelves, and consulting it on many an occasion. Such a work has reached this year its fifth edition,[1] and we congratulate the author on his well-earned success, for that success is double, since a work possessing all the qualities we have named soon gets out of date, and new editions must constantly be called for to keep it *au courant* with the march of the times.

Dr. Aitken has been fortunate enough to have his labours highly appreciated. Each edition has been rapidly sold, and as he has been conscientious enough to thoroughly revise every one and bring it down to the date of publication, he deserves his success, and we sincerely hope he may continue to meet with the same favourable reception, so that we may see another and another edition in our own time. His publishers too deserve the same good wishes, for they have brought out the work each time in a manner that does justice to

1 The Science and Practice of Medicine. By William Aitken, M.D. 2 vols. Fifth edition. London: C. Griffin & Co. 1868.

its contents. In fact, the only fault we can pick is that these heavy volumes have not had their edges cut, an omission which has cost us two hours. Multiply this by the thousands of copies sold, and there is a waste of time incurred, which we consider the binder's duty to prevent. Besides, a book of reference of such sterling value ought not to have the top edges harbouring the dust for the want of the bevilling, which costs nothing. Rather let them be gilded, for in this case they are well worth it, though we would be content with any smooth edge.

To return to the contents of the volumes. They have grown rapidly with each quickly succeeding edition. The history of the work is worth a moment's attention. The first edition appeared in October, 1857. It was founded upon the volume on medicine in the *Encyclopædia Metropolitana*, an undertaking which has always interested us in a peculiar manner. The second edition came out in 1863, and as an instance of how all parties concerned in it were watching the progress of opinion, we may mention that it appeared on toned paper, in consequence of a recommendation in the *Ophthalmic Hospital Reports*, respecting books for close reading. In that edition, too, were first introduced diagrams of temperature in febrile diseases. Only one year afterwards a third edition was called for. This shows that the author's efforts to keep up to the time were fully appreciated, and the improvements he had introduced were likely to conduce to success. With another year, another edition was wanted and ready. The book was known in all directions, and might almost expect to have passed beyond criticism. Still the author kept pace with the progress of his professional brethren. And now we have a fifth edition. There has been a little delay in this, and the reason appears at a glance. Besides many additions, we have now the "New Nomenclature of the Royal College of Physicians of London," introduced and carried consistently throughout the work. Considering that this Nomenclature is not yet absolutely published, but that early proof-sheets were procured for the purpose, no one will deny that the author is determined to be behind-hand in nothing. This Nomenclature with the addition of the foreign names of diseases must be most useful. The only possible drawback to it is that the College, so slow in issuing it, may be very hasty in modifying it, though even in that case there is little fear but that Dr. Aitken will keep pace. If any other proof were wanted of the vigilance of the author, we might mention that Dr. Letheby's Researches on Food, just published in this journal, have been laid under contribution in the chapters on the Dietetic order of zymotic diseases. Further additions to the book have also been made in such subjects as aphasia, and now we have the application of the sphygmograph described.

Such works are for reference not for criticism; we place the volumes on our shelf of books of reference, in the full assurance that we shall again and again have to take them down, and although we may not have space allotted to us for further formal review, we are certain that in the course of our literary labours we shall not seldom have occasion to cite them, and that on many such occasions we shall be tempted to wander over these pleasant pages beyond the subject respecting which we consult them.

OBSTETRICAL TRANSACTIONS.[1]

The ninth volume of Transactions of the Obstetrical Society of London has appeared. It contains the papers read to the Society during the past session, and of which abstracts have been furnished by most of the journals. Some of these papers are now illustrated by plates. One of these is coloured, and is a picture of a very singular monster, described with commendable brevity but clearness by Dr. Ross.

TESTIMONIAL TO DR. GIMSON.—Last week a testimonial was presented to Dr. Gimson in recognition of his eminent services during the prevalence of the late disastrous fever at the village of Terling. The testimonial consisted of a purse of £100, and two massive silver cups bearing suitable inscriptions. Lady Rayleigh made the presentation on behalf of the inhabitants to Dr. Gimson, who in acknowledging the testimonial, referred to the exertions of Lord Rayleigh, the Rev. F. T. Hill, Miss Luard, and others, and expressed a hope that their handsome present and kind wishes might have the effect of urging him onward in the path of duty.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 10, 1868.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THIS college is on the eve of meeting at its annual conversazione. Under ordinary circumstances, such a meeting would show the "*entente cordiale*" which ought to subsist between the two principal divisions of the body corporate. It brings with it, however, one fatal remembrance which seriously diminishes the pleasure of meeting the college authorities. It is the *finale* to an annual act of great injustice, as regards the selection of members for the Fellowship. We do not imagine that the current year will witness any change in the system of selection hitherto adopted, and which now threatens to become a standing professional scandal. "*Ardua molimur*," but we shall ever and anon recur to this matter until some re-action is produced, some inauguration of a more wise, just, and generous policy. This cannot now be very long delayed, and if some initial impulse is not soon acquired within the college walls, the requisite pressure will be applied without.

Were the college to have the honesty openly to proclaim that the Fellowship is a kind of select club, or a society to which the friends of the self-elected council alone are eligible, both the profession and the public would at once understand what such title meant, and would probably care but little to disturb the present state of things. But while the title of "Fellow" is held out (as originally intended) as the reward of superior professional ability, the greatest possible misunderstanding must prevail in the minds of the non-professional public (if, indeed, they take any kind of interest in the matter), and a very great injury is done to many members of long standing, acknowledged professional merit, and unsullied honour, in unfairly excluding them year after year.

The plain truth, however, is that the Fellowship, as of late bestowed, is no *criterion* whatever of professional superiority—thus tested it is, in many instances, as utterly worthless as a degree given "*in absentia*" by some small foreign university, and about as calculated to be the laughing-stock of the entire medical scientific world.

In bye-gone times the college numbered many illustrious men—men as great in general as in special science—and before whom lesser men could deferentially incline without the painful sacrifice of self-respect. There were, in truth, giants in those days.

At present is this broad line of demarcation seen? Does such degree of scientific difference exist as possibly to justify a few men, arrayed in brief authority, in annually excluding from the Fellowship others with equal claim to

its possession. Let us not be misled by this chance possession of official authority "*alia res sceptrum, alia, plectrum.*" If we glance (we repudiate any disrespect) at that small clique who rule, it seems at will, the College acts, how much of exalted talent shall we really find—how large a share of literary accomplishments? How many among them have deeply marked the science-track of time? We seek in vain such impress of their tread. The foot of *Hercules* looks dwarfed, the lion's claw has lost its kingly outline.

It is this discouraging comparison (forcing its way even against our will) which galls so much. Men, as we have said, can be at once modest and deferent before unquestioned mental superiority, but they become impatient of the abuse of power when wanting the attribute which could render even injustice tolerable.

It is remarkable that a large number of the Fellows of the College who, it is well-known, are anxious for reform, still stand aloof and take no action in the cause, and passing strange that journalists and even Fellows, who long ago denounced the great abuses at Lincoln's-Inn-Fields, and laboured hard, and not perhaps without success, for their redress, should yet assume so passive an attitude with regard to equally flagrant abuses in Pall-Mall. It would be interesting to learn the special reasons for this change in their emotional centres—why, while eloquently indignant at the Surgeon's corporate wrongs, they close their inkstands and their ears at the recital of those of the Physician. They would pluck the mote from out their brother's eye, wilfully unmindful of the beam so manifest in their own.

As journalists we have fearlessly expressed that which is widely though silently felt—that the College of Physicians under its present faulty, nay more, unfair management, threatens speedily to become a scientific nullity, that it is in complete disharmony with the aspirations of the day—stagnant, while liberal eddies are circling freely around. We sincerely trust that ere long, to save it from itself, more public attention will be directed to it.

THE COMING ELECTIONS AT THE UNIVERSITY OF EDINBURGH.

I.—THE CHANCELLORSHIP.

Who shall succeed Brougham? This is the question that now agitates the general council. The fitness of things would imply that a great Reformer, or at any rate a great Liberal, must of necessity be elected. Yet the obstructive party have seen fit to bring forward a thorough-going Conservative to oppose Mr. Gladstone, who had been chosen by the Liberals as unquestionably the leader of the party, and as one of the greatest scholars of the day. Personally, we have nothing to say against the Lord Justice-General; but if he should defeat Mr. Gladstone, the opprobrium that Scotland is utterly insensible to the merits of all on the south of the border will acquire new force. To compare the two men is absurd, and we shall not attempt to do so.

If mere clanship is to rule the Universities, the sooner we understand so, the better for all. Their day will then be over, and no one will pity them when they droop under the Conservative regime.

Was it not the Tory candidate who laboured to perpetuate a teaching monopoly? Is it not he who has deprived St. Andrews of the power to grant degrees after full and just examination on the plan of the London University? By this are not medical men who aspire to the doctorship now, prevented from attaining it until they are past 40 years of age, and then only at the rate of 10 per annum? A more home question—to whom else is it due that graduates in Medicine of the University of which he seeks the highest honour cannot enter the general council unless they have attended classes in that University, while no such restriction exists on graduates in Arts or Divinity?

It is idle to ignore general politics when principles lead to such results as these. In a constituency of learned men, it is monstrous that such vexatious regulations should exist, and we will not believe that in support of them, their defender will poll more votes than the foremost Liberal statesman of the day, whose scholarship also reflects credit on the age. Medical men have a great interest in such questions as these, and unless they prove true to themselves they must be content to occupy a subordinate position. For our part we magnify our calling. No learning is more elevating, no profession more worthy of honour. Let us hear no more of obstruction. The medical graduates should come to the rescue, assert the honour and influence due to them, and even though Oxford reject her most gifted son, show that the modern Athens possesses a more liberal spirit, and will not break with her glorious past to install in the place of honour the nominee of obstruction and of law.

II.—THE PRINCIPALSHIP.

Who shall succeed Brewster?

This question also is one in which medical men, not only in Edinburgh but throughout the country, possess an interest. Especially must the medical graduates of the University itself look forward to the coming election as one in which much is at stake. We have already condemned as unworthy of such a constituency the proposal to fetch a candidate from India. This outrageous notion has apparently been dropped.

It is seen that the great medical baronet, to whom humanity owes so much, could not be opposed under such conditions. We had hoped that Sir James Y. Simpson would, in the end, have been voted into the Principalship without opposition. We regret, however, to hear that such is not likely to be the case. Sir James is a Liberal, and as such must expect the opposition of those who are unable to appreciate his scientific career. It is to be hoped that opposition does not spring from that small clerical party, whose knowledge of Hebrew he once so racily exposed, and whose dislike to scientific truth assumed the guise of ignorant prejudice. Surely the members of the University as a whole cannot be insensible of the lustre Sir James reflects upon them.

We should be the last to deny that party politics may fairly be admitted to such a contest; but, if the Liberals are true to themselves, it is impossible for a Conservative to win. Let it clearly be understood that politicians who on this question "rat," will be marked men. If they are true to their colours the profession will hail its representative man in Scotland as Principal of his university.

The conservatives have hit upon a notable expedient in proposing, as they have done this week, to put up Professor Christison. This learned Toxicologist has claims that we, as medical men, should be the last to ignore. To a great extent the profession and science would find in him a representative. But beyond the circle of his own pupils it is impossible to assert that his claims would be recognised as equal to those of the discoverer of chloroform.

We regret for his own sake, and for that of *alma mater*, that his friends should have placed him in this position of opposition to Sir James Y. Simpson.

We think that Professor Christison is sufficiently honoured in representing the University at the Medical Council, where, though his learning inspires respect, he has never, so far as we are aware, created any particular impression, and where his voice is never lifted up against the wrongs under which medical men groan. The Council indeed, as a whole, has been weighed in the balance of professional opinion and found wanting. Only one or two of its members seem to comprehend their true position. The rights and privileges of their corporations move them, but the sorrows and toils of their working brethren are ignored.

Of the helpless minority that is ready to do something, Professor Christison has never proved himself one—nor do we expect he ever will.

THE SCOTTISH REFORM BILL AND ITS VOTING CLAUSES.

THE Scottish graduates seem in constant danger of being disfranchised by some oversight. It was natural in the first draft of the Scotch Reform Bill to take the clauses as to voting-papers from the English Act, which regulates the voting for Oxford and Cambridge.

It was found, however, that these clauses would not work well, and alterations were accordingly made to suit them to so scattered constituencies as those of the universities.

An attempt has now been made to recur to the plan of the English Universities. Should this be carried, it will be necessary for every voter to sign a paper, get it testified by a justice of the peace, and then get it delivered to the returning officer, *by a graduate who can make a formal declaration that he also can testify to the signature.* It is the clause we have placed in italics that endangers the privileges of the graduates of all kinds, except the few resident in the university towns. With above 1000 graduates in England and Ireland, and a still larger number scattered throughout Scotland, and having little correspondence with the towns where their universities are situated, this clause will be an almost insuperable obstacle to the free exercise of the franchise. It is bad enough to have to get a signature verified by a justice of the peace—a precaution that has never yet been required or demanded in the election of any of the high offices in the universities—not even for the Chancellorship.

How, then, will it be if such a verified document is useless, unless prescribed by a graduate who can swear to the handwriting? We look upon such a restriction as an unjustifiable attempt to diminish the number of the voters, and one which should be resisted at all cost. Every graduate will do well *at once*, for there is not a day to be lost, to exercise all his influence in the matter, and set forth as tersely as possible the wrong proposed, in a letter to his own representative, and to any M.P. with which he may be acquainted. It is absurd to say the attestation *may* in practice become a mere formality. So much the worse for the argument of those who would support it. Formalities of this kind may, and probably will, degenerate into the very worst abuses, and as we value purity of election, we should protest against anything that may introduce the most shocking iniquities into the procedure.

We understand that active steps have been taken during the last few days to prevent such an anomaly being enacted. The Secretary to the senate of the University of Edinburgh has sent a letter to the Scotch M.P.'s, and others deeply interested in the Universities have added their condemnation of the proposal in influential quarters.

Notes on Current Topics.

The Public Health.

THE deaths in London in the twenty-second week of the year were 77 below the estimate, so that the health of the metropolis continues to present a favourable appearance. Measles and small-pox both prevail at Sheffield, and the death-rate of that town for the last three weeks has been 30. It had only been 23 in the first quarter of the year.

The annual rate of mortality last week was 20 per 1000 in London, 21 in Dublin, 24 in Edinburgh, and 29 in Glasgow. The other large towns varied from 19 to 31, which was the rate at Sheffield.

The deaths in London were 1217. Of these 295 were due to zymotic diseases—the average of that class being 308. Dr. Frankland reports that the water supplied by the various companies in May, contained from 24 to 41 tons of solid foreign matters in 100,000 tons.

University of Glasgow.

THE Senate of this University, some of our readers may recollect, appointed a committee to consider the reports of the Royal Commissioners on Education, so far as they concerned elementary schools in relation to universities. This committee has issued a lengthy report, touching on all the questions involved. The committee seems to have been at great pains to collect trustworthy information. It even circulated a series of printed questions among the university students of all the faculties, in order to ascertain the schools frequented prior to entering the classes. From the answers returned, it appears that out of 898 students, no less than 371 had obtained all their previous instruction at the elementary schools, while 206 others had partially availed themselves of these schools. At the middle-class schools 236 had received their education.

Only 85 had been educated out of Scotland or at private schools. Besides this, it was further discovered that a considerable proportion of the teachers amongst the students had attended the elementary schools; some of these had been pupil-teachers; others, and not a small proportion, only had found it no easy matter to contrive to gain their University education.

Looking at these statistics we are not surprised to find that the Committee would deprecate any system that would tend to lower the education of the elementary schools. They hold that it would be unwise to introduce any system of training masters that would increase the difficulty of attending at a University. It should rather, they seem to think, be the object to afford greater facilities for University education. It will no doubt be generally believed that any change that may be proposed ought, if not to enforce, at least to encourage attendance on the classes in the University.

The Committee express unqualified condemnation of the idea that the State should only pay for the most elementary education, but it is more doubtful whether on this point their opinion will be as readily trusted; as petitions are to be presented to Parliament we shall not improbably recur to the subject. Meantime we may remark that the present system has sent a large number of young men to the Universities, and has, consequently, a high claim on the consideration of all. That consideration will, no doubt, be given. We conclude by mentioning that the Committee urges that "it is by raising the qualifications, the pay, and the social position of teachers that the interests of education are really and surely to be advanced, and not by screwing down the teacher to a hard mechanical system, and jealously withholding from him a portion of his inadequate remuneration on the slightest apparent symptom of a failure of duty."

Winter at Mentone.

A CORRESPONDENT of the *Times* has revealed some of his sufferings last winter at Mentone, and the great journal has devoted a leader to denounce the filth and the extortions to which unfortunate invalids in search of pure air and a warm climate are too frequently subjected. We have a very vivid recollection of these evils, and have often wondered how patients can put up with them—still

more how doctors who have seen and smelt the abominations of foreign health resorts can refrain from bitter invectives about them. When Mentone was rising into favour, we leaned over a wall to look down upon some water, and inhaled —— well, we will not attempt to describe the sickening smell of the gases that at once prostrated us. We have since been farther, and seen things as bad—and smelt them too. There is no reason why Englishmen able and willing to pay for decent accommodation should, year after year, inhabit pestiferous dwellings, paying for them extortionate prices. There are plenty of spots much better in every point of view than Mentone, which has been advertised up to its present popularity by one or two enterprising persons, whose descriptions ought to be received *cum grano salis*. We think it the duty of those who really believe in the virtues of this climate, to lend their help to their suffering friends to deliver them from its incidental dangers. This help is not given by extolling the advantages and ignoring the disadvantages of the place.

Havre Maritime Exhibition.

This institution has been formally opened, although at present it is far from complete. The space occupied is no less than twenty acres, and the building is elegant. Havre is a pleasant place to visit: the town is tidy, the buildings good, the scenery picturesque. Apart from the exhibition, an autumn visit would be likely to satisfy English travellers more than half the French towns more frequently brought under notice, so that this year, with its maritime exhibition, it may surely count on an influx of British tourists.

The most striking attraction will, we expect, be the monster aquarium, the largest of the kind ever built, where all sorts of creatures whose home is the sea, disport themselves in their native element, pumped up by steam-engines working day and night.

The Medical Congress is as yet but an embryo, and there seems some doubt if it will grow.

Professor Humphry and the Royal College of Surgeons of England.

We have now to add to the list of candidates for a seat in the Council the name of Professor G. M. Humphry, of Cambridge. The name is familiar enough to our readers, and will, no doubt, attract considerable support. The claims of Prof. Humphry as a leading scientific investigator, surgeon, and teacher, require no comment. Many provincial Fellows will, no doubt, vote for him, as a representative of the provinces, and we shall not be surprised if at this late period he should obtain a seat.

Parasitic Diseases.

The theory of epidemic disease which proceeds on the supposition of the propagation of a fungus, will receive elucidation at the hands of Dr. Thudicum, who is about to read a communication at the Microscopic Society of King's College on the subject this evening.

Licensed Detention of Lunatics.

By the decision of five judges in an appeal case, a highly important point in reference to the reception of lunatics in unlicensed houses has been decided. A person named Shaw had been convicted of taking charge of an imbecile and paralytic patient, of fifty-five years of age, whom he had grossly neglected. The question was whether the patient was a lunatic within the meaning of the Act, he being inoffensive and suffered to be at large. The Court unanimously declared that unsoundness of mind in any form, such as renders special care essential, comes under the provisions of the Act.

A New Extract of Liebig's Food.

No doubt every medical man who is called upon frequently to treat the diseases of hand-reared children has already tried Liebig's food, and probably has, like ourselves, more than once been disappointed with the preparation supplied under that name. And yet the physiologist will not thereby have lost all faith in Liebig. He will observe that the process requires very nice management. The microscope may have shown to any one determined to trace the cause of failure, that in some cases the husks have not been removed from the malt. We have ourselves seen specimens in which Liebig's process had not been properly followed. Some persons have sold various starchy foods under the shadow of the great chemist's name. But all these cases do not affect the value of the process, and the only one worth our notice here is that in which the process, honestly followed, has not been conducted with sufficient nicety.

Since 1845, when Mialhe announced his discovery of the reduction of starch by means of diastase, medical men have directed their attention to the first process of digestion, as effected by the saliva. It has, however, been pointed out by Mialhe himself that infants of tender age can scarcely digest starchy foods at all, and if biscuits have proved more easily digested, it is because a portion of the amylaceous matter has been transformed during the cooking into dextrine or glucose, just as it is changed by the diastase of the saliva in mastication. Now, Liebig's process ought thus to change the starch into dextrine, and when carefully carried out it will do so.

In noticing a pamphlet last year we announced that a company had been formed for the supply of Liebig's food in a liquid form. The difficulties and inconveniences of this plan may be readily imagined. We are, therefore, glad to state that a few months ago we found that Mr. Mellin had obtained by very carefully evaporating the liquid, a solid extract which would keep for any length of time. We have waited for this time to make a further trial of it, and can report strongly in its favour. As prepared for sale, it is a brownish, coarse powder, exceedingly soluble in water; in fact, almost deliquescent, so that it requires to be kept in stoppered bottles (in which it is supplied). It has an agreeable sweetish taste, and only has to be dissolved in warm milk and water, an operation lasting only one minute, to produce a fluid closely approximating to human milk. We have carefully tested samples of it, and have found that the flour has really been transformed into dextrine. The greatest value of this extract is that it will keep for any length of time in any climate. India will probably be a large consumer. It is a preparation which medical men ought to examine.

Irish Coroner's Law.

We are sorry to be compelled to illustrate the observations which we made lately on the complete inefficiency of the inquest system in Ireland at the expense of a medical man, but in a public cause individual considerations must stand aside. We declared our belief that in the majority of instances Irish coroners' juries (and we have no reason to

believe that they are worse than English) are so utterly incapacitated by want of education from forming a clear judgment that their interference with the dictation of the verdict by the coroner is almost certainly for the worse. *Exempli gratia.* A man is killed under the most obscure and suspicious circumstances, as alleged by an accidental fall from his horse, at one o'clock in the morning, on a deserted road, and in company with a person who had been heard using threatening language to him. The *Irish Times* informs us that on the next day (Sunday) an inquest was held before Dr. Carter, one of the coroners for the county Kildare, at which inquest the father of Mr. Allen (the person who had been in the deceased's company at the time of his death) was foreman, and it is alleged that the only evidence adduced was that of Mr. Allen's son, which was not taken before the jury, but in an adjoining room, and then brought in and read to them, and asked was not their verdict "Accidental death," which they returned. So passed over the first inquest, and when the facts became known the matter was represented to the Castle authorities, who sent an order to have the body exhumed, a post-mortem examination made, and this inquiry instituted. If this statement be true, it, in itself, is demuratory of the system under which such legal "cooking" is possible. In any case a system under which juries are found to permit such a gross abuse can inspire no confidence.

Superannuation of Poor-law Medical Officers in Ireland.

The Local Officers' Superannuation Bill of Sir Colman O'Loghlen, in which the hopes of the Dispensary and Union Medical Officers of Ireland is, as regards their long-looked-for retiring allowances, centred, has been amended by the Honourable Baronet, by the introduction of the Boards of Guardians in the list of those bodies which, should the bill become law, will be empowered to grant pensions to aged or infirm officers. In making this addition to his bill, Sir Colman O'Loghlen has promptly responded to the representations of the profession in Ireland, and it remains for our brethren to ensure for the Bill, and more especially for this addition, the hearty support of the Members of the House. We most earnestly urge upon our readers that fortune has now placed at their feet not only the occasion, but the most favourable moment for exercising their just influence on the House of Commons. If they lay before their local representatives the arguments which have been so often urged in favour of the demand, and second their request by an explicit declaration of their intentions as to the approaching election, reason and policy will forcibly enforce their representations.

Elephant Hunting.

We remarked a week or two since on the wonderful story told by the *Pall Mall Gazette* respecting the exploits of a surgeon with the Abyssinian force, which were to be equalled only by the great Baron Munchausen.

The origin of the story is now said to be a hoax, and our contemporary thus writes:—

"We now learn from a correspondent at Zoulla that the account in question was read, when our paper arrived there, with shouts of laughter, the hero of the adventure being by no means a sporting prophet among his own comrades, and being notoriously afflicted with a disease not uncommon among African explorers, known as 'elephantiasis of the imagination.' The letter from Zoulla declares that the only elephant the sportsman had to deal with was a commissariat animal, and that the gesticulations and shouts of the natives, uttered in a tongue which he did not understand, were merely earnest remonstrances against firing at that inoffensive and useful animal, which, however, escaped all injury."—*Pall Mall Gazette.*

Testimonials to medical men seem to be rather frequent just now. We hear it is proposed that on his retirement from the office of Physician to Charing-cross Hospital, Dr. Chowne shall be presented with a substantial proof that his long and valuable services have met with the appreciation of the governors and friends of the hospital.

In the House of Commons on Thursday last a petition was presented by the Chancellor of the Exchequer, from physicians, surgeons, and others connected with the science and practice of medicine in and around London in favour of the Electric Telegraph Bill.

Foreign Medical Literature.

ON THE COMPARATIVE ACTION OF VARIOUS DISINFECTING AGENTS,

WITH REFERENCE TO THE PURIFICATION OF SHIPS' BILGES.

By Dr. BERENGER-FERAUD,

SURGEON IN THE FRENCH IMPERIAL NAVY.[1]

All seamen, and indeed most persons who have past any considerable length of time on board ship, know how disagreeable are the effluvia which arise from the bilges. Naval medical men have constant opportunities of observing the troublesome, and occasionally dangerous, effects on the health, of such emanations. I need not, consequently, enlarge on the utility of researches on this subject.

My first experiments on the means of purifying ships' holds were undertaken a good many years ago. I incidentally made allusion to them in my inaugural thesis of 1860. In the autumn of 1863, and the following spring, I resumed the inquiry on board the Imperial yacht "Jerome Napoleon," to which I had been appointed surgeon, and instituted comparative trials of the disinfecting action of various agents. The substances on which I experimented were—wood charcoal, chlorine, chloride of lime, carbolic acid, proto-sulphate of iron, and permanganate of potash.

The "Jerome Napoleon" is a wooden screw-steamer of 200 horse-power, which was launched in 1860, from one of the Channel dockyards. Built on very fine lines, her bilges, fore and aft, are very confined and difficult of access. The relatively large quantities of stores which she is required to carry when at sea, causes every foot of available space to be occupied, and the accommodation for passengers and crew to be inconveniently curtailed. She had not been long cleared out of dock, and anchored ready for sailing, when a wind on shore, which caused some rolling, gave rise to a most disagreeable odour of bilge water, which, on the deck occupied by the crew, was almost insupportable. With the object of overcoming this nuisance, I undertook the experiments of which the following is a short account:—

1. *Wood Charcoal.*—On a day when the smell was very offensive, I placed in the lowermost part of the bilges ten thin pack-sheet sacks, containing each twelve pounds of charcoal. Not the smallest diminution of odour was perceptible. This experiment was several times repeated, but on each occasion gave the same negative result. Thereupon, I put a quart of the stinking bilge-water into a pail, and gradually added charcoal, carefully watching the effect. No sensible decrease of smell was noticed, till sufficient charcoal had been introduced to rise four inches above the surface of the bilge-water in the pail, and the whole had been kept in that state several hours. To produce any disinfecting effect, from six to eight quarts of charcoal to one of foul bilge-water were necessary, and even then the success was very doubtful. When the laudations that have been bestowed on charcoal as a disinfectant are re-

[1] Translated for The Medical Press and Circular, from *Archives de Médecine Navale*, the organ of the French naval medical service, edited by Dr. Le Roy de Méricourt, Professor of the School of Naval Medicine.

membered, its inefficiency in the above circumstances appears somewhat remarkable.[1] The enormous quantity which would be required to produce any result, even if that result were more complete, renders the use of charcoal utterly impracticable.

2. *Chlorine and Chloride of Lime.*—Abundant fumigations with chlorine had only the effect of modifying the smell, and of producing a compound odour as offensive as the one complained of. Moreover, the 'tween-decks were rendered almost uninhabitable for the time, and the air in the hold totally unfit for respiration. No better effect was obtained from chloride of lime, neither when thrown into the bilges, nor when exposed in dishes placed in the hold.

Thus, as a remedy for the smell from bilge-water, both chlorine and chloride of lime completely failed in my hands. But their injurious action on the engine and other metallic objects on board was not long in becoming apparent. I had an opportunity of observing what it would be under the prolonged exhalation of chlorous gases, from having left during a month an open jar of chloride of lime in one of the cabins of the "Jerome Napoleon." All the locks and keys, and every thing composed of metal were seriously injured, and even the bolts and fastenings of the vessel inside the cabin were, to some extent, attacked.

3. *Carbolic Acid.*—This substance was tried on the faith of the assertions contained in the work of Dr. Lemaire, of Caen. But its own odour is so offensive that I did not venture to experiment with it on the large scale. I added a couple of drams of pure carbolic acid to a quart of bilge water. The original fetid odour disappeared; but whether it was destroyed or only overpowered and masked, by combination with the smell of the agent used, could not be determined.

Having repeated this experiment several times, I am inclined to think that the power of carbolic acid to remove the odour of bilge-water is very feeble; for I found that a piece of silver plunged into that fluid, after treatment with carbolic acid, was quite as much blackened by it as by the bilge-water to which no carbolic acid had been added. The odour peculiar to carbolic acid is so penetrating and disagreeable, as to have prevented me using it in the bilges of the "Jerome Napoleon." I feel satisfied, however, that those who may venture to try it in the bilges, will find that this substance only substitutes for the smell which they emit, another equally offensive, if not perhaps so injurious to health.

4. *Protosulphate of Iron.*—One ounce of this substance in crystals, added to eight ounces of bilge-water removed the offensive smell in an hour and a-half. One pound placed in a bucket containing two gallons of foul bilge-water, gave the same result after four hours. These experiments are similar to some which have been published by Dr. Forné, of the Imperial Navy; but it is curious that whereas mine appeared to me to be successful, those made by him on board a vessel of the Mexican Squadron seemed to give negative results. I have tried to account for this difference, and have conceived it to arise from the circumstance that, in the latter case, sufficient length of time was not allowed for the action of the protosulphate, or else that the solution used was not recent enough.

In my experiments I employed the protosulphate in crystals instead of in solution, and I am inclined to think that when the bilge-water to be disinfected is in considerable quantity, crystals ought to be preferred. In fact, protosulphate of iron, soon after being dissolved, undergoes reduction by oxidation, which diminishes its disinfecting power. I tried the effects of a recently made solution composed of three ounces of crystals to eight ounces of water, and then of a solution of the same strength which had been kept some time. The former, which was of a greenish colour, acted powerfully on fetid bilge-water, whereas the latter, which at the end of a week, had become reddish in colour, and had thrown down a precipitate like brick-dust, exerted no sensible action.

It is my opinion, then, that in practice, the crystals of protosulphate of iron ought to be placed in the bilges without being previously dissolved, and a freshly made solution used for washing down the boards and wood-work.

5. *Permanganate of potash.*—I now come to the last of the disinfectants tried by me, and I may add, the best. The powerful action of this substance on the odours exhaled by suppurating surfaces is, at present, well-known. The medical journals, and in particular the *Gazette des Hopitaux*, and the *Bulletin Général de Thérapeutique*, have called attention so emphatically to this point, as to give rise to very great expectations from this new agent.[1] For my own part, I had seen in the hospital practice of several of the Paris surgeons, and particularly in that of Dr. Demarquay, as well as in my own, such admirable results from its disinfecting action on wounds, as to cause me to think that it might be found of great use for the purification of ships' bilges.

I made use of a solution of permanganate of potash, of the strength of half an ounce of crystals to a quart of water. One ounce and a-half of this solution, which has a fine crimson colour, added to a pint of foul bilge-water, effectually removed all bad odour in three minutes, with change of colour to a dirty greyish brown. Five ounces of solution in four quarts of stinking bilge-water produced the same result. Two quarts of solution sufficed to destroy rapidly the bad smell of the after-bilges of the "Jerome Napoleon."

The purifying action of permanganate of potash is so remarkable, that its success in the disinfection of putrid matters of every kind may safely be assumed. I have derived the greatest advantage from its use for many other sanitary purposes besides those just mentioned. It not only effectually destroys the foul odours arising from suppurations, and from putrefying and fecal matters, but it acts likewise on many other odorous substances. I will cite a curious fact in confirmation of this. Having one day inadvertently imbued my hands with a concentrated solution of carbolic acid, I could not rid myself of the penetrating and offensive smell. Repeated washings with soap, followed by applications of vinegar, chloride of lime and ammonia, failed to remove the odour. Being on the point of attending a consultation to which I was very reluctant to carry so nasty a smell, I was in despair. The idea came into my head to dip my fingers in permanganate solution. The first application caused a notable diminution of the carbolical odour; after the third it had entirely gone. Struck with the result, I afterwards repeated the experiment, which each time succeeded perfectly. This fact cannot fail to prove useful to those who may have dissections and post-mortems to make.

I am satisfied that all those of my fellow-medical officers who shall repeat my experiments on board their ships, will obtain the same good results from permanganate of potash. But there is, unfortunately, against this valuable agent a somewhat serious objection, which may for some considerable time impede its general use: its commercial price is excessively high. There can, however, be little doubt that, when it shall have become an article of current sale, and an industrial instead of a laboratory product, the price will rapidly diminish.[2] At all events, the present high price of permanganate of potash need not, even now, prevent its employment with great advantage in a considerable number of cases, because of the superior rapidity and efficacy of its action.

CONCLUSIONS:

1. Wood charcoal is radically inefficient and inapplicable.
2. Chlorine and chloride of lime are hurtful as well as inefficient.
3. Carbolic acid is of no use, and has an insupportable odour.
4. Protosulphate of iron may for the present be preferred; it is sufficiently active to be of considerable use, and very low in price.
5. Permanganate of potash is infinitely superior to all the preceding substances, and is destined to put them all into the shade so soon as it can be sold at a figure permitting its use on the large scale. Even its present price is no bar to its employment, when it is necessary rapidly and completely to purify a ship's fetid bilges.

1 It is now well-known that wood charcoal has little or no disinfecting action when immersed in liquids. In the air it has the power, in common with many other porous bodies, of neutralising certain gaseous products of decomposition, by reason of the condensed oxygen which, in those circumstances, it contains. This is why, in the above experiment, it produced no effect until sufficient had been added to rise above the surface of the liquid.—Tr.

1 The very earliest notice contained in any Fench medical writing of the disinfecting properties of permanganate of potash, appeared in the *Gazette des Hôpitaux* of the 4th October, 1862, and was occasioned by the remarkable success of the experiments made by Dr. Demarquay at the *Maison Municipale de Santé*, in consequence of the good effects which that gentleman had witnessed at the London hospitals, when he was in this country during the International Exhibition of 1862. At that time the discovery of the disinfecting properties of the alkaline permanganates had already been more than six years before the English public, and there had been read at the *Académie de Médecine* of Paris the year previous, namely, on the 17th September, 1861, a memoir on the subject, by Mr. Condy, the author of that discovery. The latter was the very first occasion on which this matter had ever been publicly spoken of in France.—Tr.

2 This is precisely what has taken place in this country, thanks to the enterprise of Mr. Condy, who has been enabled to apply to its manufacture on the large scale, economical methods which are out of place in the laboratory. At the date of his patent, permanganate of potash could not be sold under 80s. per pound; the price now of a pint of concentrated solution is 1s.—Tr.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE twenty-sixth annual meeting of this Society was held on Monday, June 1, at the King and Queen's College of Physicians, Kildare-street.

Dr. CHURCHILL, President, in the Chair.

Amongst those present were:—

Sir Dominic Corrigan, Drs. Thornhill, Chaplin (Kildare), Mackesy (Waterford), White, Porter, Molony (Tulla), Morrogh, Fitzpatrick, Duke, Gordon, Hardy, Churchill, Beatty, Johnson (Kilkenny), Irvine, Duncan, Daly, Mollan, Little, Croker, M'Clelland, M'Clintock, Pollock, Hardy, Benson, Benson, jun., Grimshaw, Maguire, Darley, Eustace, Stewart (Lucan), Guinness, Nugent (Drogheda), Martin Portlaw), Hamerton (Navan), Jacob (Maryborough), Battersby, Bradshaw (Bansha), Kennedy, Holland, Law, Hynes (Kinvara), James F. Duncan, W. Moore, Adams, Wharton, Dwyer, Athill, Osbrey, Quinan, Edward Hamilton, Robert M'Donnell, William Stokes, Speedy, Coulton, Sibthorpe, Brady, Hanrahan (Montrath), Willis, Barton, Morrisey (Tipperary), Hargrave, Byrne, Hatchell, Cronyn.

The CHAIRMAN said:—

Gentlemen,—It is with great pleasure that I welcome you to the College of Physicians, on this the twenty-sixth anniversary of the Royal Medical Benevolent Fund Society, and I need hardly add, that I feel it a great honour to preside at it.

I shall not detain you long by any preliminary remarks, but having for many years taken a deep interest in the Society, and watched its working, I am anxious to say a few plain words upon its present condition.

The object of your Society is laid down so broadly and clearly in the motto on the title-page of our reports, that I cannot do better than quote it:—"If there be among you a poor man of one of thy brethren, within any of thy gates, in the land which the Lord thy God giveth thee; thou shalt not harden thy heart, nor shut thine hand from thy poor brother; but thou shall open thine hand wide unto him, and shalt surely lend him sufficient for his need, in that which he wanteth."

If any one is ignorant how thoroughly the recipients of your bounty are described by the first part of this verse, a glance at the book on the table will satisfy him at once. He will find there the records of medical men, our brethren, accustomed to the comforts, and some to the luxuries and refinements of life, arrested by illness or other casualty, and dependant for a great part of their means of living upon the allowance you give them. He will find also, the widows and children of medical men, reduced by their death to utter destitution, and thankful even for the mite we are able to afford them. These are they whose needs appeal most earnestly, most urgently to your liberality. Eighty-one of them, our brethren, are on our list for this year.

Gentlemen, you little know how sad a task is laid upon your Council to examine into all these sorrowful claims, and to contrive, not, alas, how liberally "with an open hand," we can contribute to their necessities, but how we can pare down each sum to the lowest point, so as to give each a little, and yet keep out of debt.

Although no one will dispute the principle that we ought to help our less fortunate brethren and sisters, yet, strange to say, our practice has not as yet kept pace with it.

There are about 2000 medical men in Ireland, and only about 480 are subscribers to our Society.

After twenty-six years of strenuous effort on the part of your Council and local Committees, the subscriptions (not including the interest upon donations) only amount to about £350.

Why, if each practitioner in Ireland gave only 5s. a-year (and many give very much more) we should have £500 per annum, but calculating the subscriptions of those who give more, I suppose our receipts would be £800 per annum, which, with the addition of the interest upon our funded property, would enable us to relieve a larger number of applicants, or to give more adequate relief to the present recipients.

I confess I do not find it easy to understand this withholding of help by men whose daily ministrations are, to a large extent, works of charity. Did any one ever know a medical man refuse his services to a poor man because he had not wherewith to pay for it? Do not our brethren give their time, their labour, their skill, aye, and often their money, to the poor and afflicted?

Why, then, should they hesitate to devote a little of their means to help those who, in a double sense, are their brethren, and who have thus a twofold claim, upon whom affliction and destitution have fallen. One would think that the sight of a brother practitioner, incapacitated from earning a living; or of his widow and orphans left to the cold mercies of the world, would appeal to the compassion of every one; or if not, would at least remind us that as they are, so we and ours may be if God so will. No doubt the larger number of our profession do not abound in wealth, and to expect much from many of them would be very unreasonable, but we do not ask much; we ask ever so little, only let there be something from all, that all may share in this good and charitable work.

I have more than once heard it assigned as a reason for not assisting us, that the subscribers to the fund gain thereby no benefit to themselves or their families. Certainly not in the way they mean, because this is not an insurance society, but in a modified sense it is not quite true. No subscription gives a legal claim to an annuity; but in cases of necessity the moral claim based on previous subscription is never ignored, and among the recipients of your bounty there are several who have been more liberally dealt with in consequence of having been subscribers; just as there are others mainly dependent upon you, who never dreamt that they or theirs could ever need help.

Thus you see, to take the lowest ground, a subscription is not necessarily thrown away.

But surely, gentlemen, whether we derive benefit to ourselves in this way or not, there are other ways in which we gain personally and collectively.

That "charity is twice blessed," is a truth of such universal experience, that it has passed into a proverb. It "blesses him that gives as well as him who receives." There is nothing which gives such influence to a medical man as the power of sympathizing, and nothing confers this like doing good to others. Nothing keeps the heart and feelings so fresh amid the wear and tear of professional life; nothing which gives greater satisfaction under disappointments, and nothing which adds a greater zest to the successes of our career.

"Doing good, hoping for nothing again," ennobles that character of whom it is a noble trait. It is following in His footsteps "who went about doing good," and who declared of the service of charity—"Inasmuch as ye have done it unto one of the least of these My brethren, ye have done it unto Me."

Neither does our Profession gain less collectively by supporting liberally such a Society as this. Most of you, I dare say, have this day attended the meeting of an excellent society (the Irish Medical Association), whose object is to promote union and united action on the part of the whole Profession. A most admirable object, and one, I take the liberty of saying, which is not less promoted by our Society. Depend upon it, united effort on behalf of the suffering, the destitute, and the helpless, is a great bond of union among the helpers.

Almost co-extensive with the efforts we make to help each other will be the growth of the feeling of brotherhood and the strength of the tie which binds us together.

The union—and, if I may use the phrase, the cohesion—resulting from beneficent action will be found to resist a greater strain than union for most other purposes.

In conclusion, gentlemen, I do earnestly trust that we shall all exert ourselves to increase the number of our

members, whether their subscriptions be small or great, and that the result next year will bear a noble evidence of your success. Not for gain, but for charity; not for reward, but because "to him that knoweth to do good, and doeth it not, to him it is sin."

Dr. M'Clintock then read the Annual Report, which, although in type, we are compelled to hold over.

Sir Dominic Corrigan, Bart., moved that the report and statement of accounts be adopted, and that 1500 copies be printed for circulation. He said he heard with great pleasure that the trustees had not availed themselves of the power given to them at the last meeting of transferring stock to the amount of £13,000 from Government securities to some other securities; and he wished to avail himself of the opportunity now afforded him of expressing the gratification he felt at the course pursued by the trustees, and to hope that they would not transfer their stock to any other than Government Stock. All other undertakings were liable to contingencies, if not of failure at least of delay; and although they might get from one to two per cent. more interest on other securities, there might be delay in payment from any other fund. They should keep their funds where they now were. This was not an assurance society, but one that called on the members to contribute each according to his means. Sir Dominic Corrigan then concluded by proposing the resolution.

Dr. Mackesy seconded the motion, and expressed his regret at learning from the report that so much apathy was shown on the part of many members of the profession towards the objects of the society. He would have been better pleased, he said, to find this institution supported by a large number of names, although the individual subscriptions were small, than by a small number of names amounting to large subscriptions. He urged that the profession should warmly support the society, and, amidst applause, added ten pounds to the ninety pounds which he had previously subscribed to the society.

Dr. Benson suggested that a paragraph should be added to the report stating that the Society were gratified to find that the portrait of Dr. Kingsley, the founder of the society, had been given its proper place in the College of Surgeons.

Sir Dominic Corrigan, as the mover of the resolution for the adoption of the report, and Dr. Mackesy as the seconder, said they had great pleasure in adopting the suggestion of Dr. Benson, and the council concurring,

The Chairman put the motion for the adoption of the report with Dr. Benson's paragraph added.

The motion was carried unanimously.

Dr. Porter, President of the College of Surgeons, said he was pleased that his first act in his official position since his appointment was to come forward to advocate the claims of the Society by moving that the meeting desired to express its warm thanks to the various provincial branches of the association, and to the Hon. Sec. and Treasurers for their continued zeal in promoting the objects of the Society.

Dr. Beatty seconded the motion, and suggested that, in order to secure a better support for their funds in future, and as a means of guarding against the apathy heretofore exhibited, a gentleman should be appointed to solicit subscriptions in each locality.

Dr. Benson was of opinion that the hon. secretaries and treasurers of the parent society should also be thanked for the zeal and efficiency with which they had performed their offices, and the readiness and punctuality with which they rendered invaluable services.

The suggestion was adopted, and the resolution was then passed unanimously.

Dr. Morrogh proposed the thanks of the meeting to the Press.

Dr. Martin, Portlaw, seconded the motion, which was also adopted.

The President of the College of Surgeons having been called to the second chair,

On the motion of Dr. Molony, seconded by Dr. Fitzpatrick, the thanks of the meeting were passed to the President.——The meeting then terminated.

Correspondence.

THE MEDICO-POLITICAL ASSOCIATION AND MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In reply to Dr. Drysdale's letter of the 27th ult., I beg to say that I think several of his suggestions very good. Before I saw his letter I had thought over most of them, and written on the subject to some of the executive officers of our Association.

I can assure him that no endeavour of mine shall be wanting to bring the subject matter of his communication before our Association, which, I trust, will soon number Dr. Drysdale among its members.

My notion is that the Medical Council should represent the body of the profession directly as well as indirectly, through the universities and corporations.

That the Medical Council should have power to exercise a larger amount of control in making the degree of M.D., one not easy of attainment, and that it should be a sufficient guarantee that who ever holds such degrees from a British University, has received a complete medical and general education.

The same remarks apply to the degrees of Bachelor and Master in Surgery.

A similar power should be exercised over the Colleges of Physicians and Surgeons, so that these bodies should not have the option of creating new qualifications just as they please, and that their Fellowships should become *real* marks of distinction.

I would suggest that a Central Board of Examiners be appointed from the present examining bodies, for each division of the United Kingdom, that every person entering the profession should be examined by this Board, their general educational attainments having been previously tested by an examining body appointed in the same manner. That the passing the medical examination above-mentioned should entitle the holder of its license or diploma to practise as a general practitioner, and confer upon him the designation of Physician-Surgeon or Surgeon-Physician, but not that of Doctor either by right or courtesy.

I also advocate Dr. Drysdale's suggestion No. 2, that Poor-law Medical Officers should be paid a sufficient salary to enable them to devote their whole time to the duties, but in addition that they should not be called on to find drugs or appliances, that their appointment or dismissal should not rest with Boards of Guardians, and that they should have a seat at these Boards.

That the appointment to all public medical situations be made by open competition, has my full support, for I consider the present system of gross nepotism which exists in connection with, as well as the degrading system of canvassing for public appointments, to be a disgrace to the country and our profession.

To prove that some control should be exercised over the Corporations in regard to their examinations, I have only to point out the recent examination for the Fellowship of the College of Surgeons. To make matters easy the examination has been divided into two. Fifty-three passed the first in Anatomy and Physiology, a week or so since. I quite agree with a medical contemporary that the papers were such as any first year's man could have answered well.

Now, sir, the Fellowship of the College of Surgeons has already dwindled down to a very low value, for it has become quite common, inasmuch as for several years it has been sold to all-comers for ten guineas, and now one can easily see that the College intends that it should be equally or nearly as easy of acquirement for the future, in fact, an almost £ s. d. arrangement. For my own part I am rather ashamed of being a F.R.C.S.

Trusting that you will not consider this letter too long for insertion, and promising not to trespass at such length again, I remain, &c.,

R. P. B. Taaffe, M.D., M.S.Lond.

Brighton, June 5, 1868.

"THE PHARMACY ACT, 1868."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your impression of last week I noticed a paragraph on Lord Granville's Bill respecting chemists and druggists.

Being interested in the matter, I should esteem it a favour if you would inform me, through the medium of your valuable journal, whether the said Bill will contain any clause preventing grocers retailing drugs, and if not, what particular advantage will it secure to chemists, and what advantages will accrue for the expenditure of time and money in passing the Pharmaceutical Society, as the generality of grocers now deal in drugs. Any further information on the subject which you could, in fairness to the body of your readers, furnish, would be esteemed by, sir, yours truly, J. E. WILLAN, M.D.

Haxey, Nr. Bawtry.

[THE first section of the Bill provides—

"From and after the 31st day of December, 1868, it shall be unlawful for ANY person to keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title 'chemist and druggist,' or chemist or druggist, in *any* part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act."

And again, section three—

"Chemists and druggists within the meaning of this Act shall consist of all persons who, at any time heretofore, have carried on, in Great Britain, the business of a chemist and druggist, in the keeping of open shop for the compounding of the prescriptions of duly-qualified medical practitioners, also of all assistants and associates duly registered under or according to the provisions of the Pharmacy Act, and also of all such persons as may be duly registered under this Act."

The Bill, which is to be cited the "Pharmacy Act, 1868," is too long to be given *in extenso* in our columns; but the above quotations will probably answer the purpose of our correspondent.—ED. M. P. & C.]

Medical News.

CANCER HOSPITAL (LONDON AND BROMPTON).—At the annual general meeting of the governors of this hospital held on Friday last, it was stated that during the year new plans of treatment, both local and general, had been employed with highly beneficial results. The patients were now seen five times a week, instead of four as formerly. The financial statement showed that the legacies during the year had amounted to nearly £10,000; the receipts from all sources had amounted to £14,564, 10s. 9d.; the total expenditure had amounted to £5175, 7s. 11d., and there was a balance in the hands of the bankers of £1600. The report and accounts, which were considered eminently satisfactory, were unanimously adopted. The chairman remarked on the very gratifying position the hospital was placed by the legacies received during the year, showing that the public recognized the extremely valuable nature of the charity, which was designed for the relief of one of the most distressing maladies to which human nature was liable. The proceedings then closed in the usual manner.

UNIVERSITY OF EDINBURGH.—THE VACANT CHANCELLORSHIP.—A meeting of the General Committee for promoting the return of Mr. Gladstone, as Chancellor of the University of Edinburgh, was held on June 1st, Sir James Y. Simpson occupied the chair, and there was a large attendance. The Chairman, in his opening speech, referred to the steps they had taken in regard to the Chancellorship. He said that they had calmly considered as possible candidates Lord Russell, Lord Dalhousie, the Marquis of Salisbury, Lord Colonsay, the Lord Justice-General, Sir William Stirling-Maxwell, Sir Roderick Murchison and others. But the general conclusion was at last arrived at, that if they should select for the office the man of the day who was most distinguished in literature, philosophy, and other acquirements, their choice should fall upon Mr. Gladstone. In that Right Hon. gentleman, they had that combination of name, fame, power, and talent, which they require in a Chancellor. He was a distinguished author, one of the greatest scholars, greatest orators, greatest legislators, and greatest statesmen living—a man whom they all knew would one day, and that perhaps at a very early day, be Premier of England. He presented altogether a combination of gigantic claims and talents such as it was almost impossible to meet with in any other one person. Addresses were also delivered by the Rev. Sir Henry Moncrieff, the Rev. Dr. Guthrie, Professor Lyon Playfair, Dr. Alexander Wood, and others. Professor Lyon Playfair said that the first and most important objection that had been taken to Mr. Gladstone was that he was determined to reduce the four universities of Scotland to the state of colleges, and to put them into one national University. On that subject he read the following letter received from Mr. Gladstone:—"In 1858 I held an opinion, more than a year before I was chosen rector, that the value of Scottish degrees, especially those other than medical, would be enhanced if the four universities of Scotland formed themselves into one national university. But this was (see "Hansard," vol. 151, p. 740) 'presuming a willingness was found to combine in this way.' This willingness is repeated over and over again, and is the basis of the whole affair as it was then treated by me; and perhaps I may observe that the clause which I moved provided only for action, 'with the consent of such universities respectively,' so that even if three universities had desired the connection the fourth could have stopped it. This plan was approved by Lord Elcho and Mr. Dunlop, and opposed by no one. The then Lord Advocate Inglis suggested its further consideration. It was brought up again on the report of the Bill, and agreed to by him and by the whole house. The form of it had been altered, and, singularly enough, as it now stands it allows each university singly to join a national university. I have no means at this moment of accounting for the alteration of the clause with certainty, but my decided impression is that it was probably redrawn at the instance, if not under the direction of the then Lord Advocate, and thus brought into a form less favourable to the free agency of the Scottish universities, though still recognising it pretty largely. My recollection is that this proposal to empower the Scottish universities to unite was very acceptable at the time to Scotch members generally. I think this history of the nature and limits of my proposal—founded on documents accessible to all—is better than any profession I can now make. Since the date of it, the subject has been dismissed from my mind, like many others, for the simple reason that the first condition required for giving it vitality did not appear to exist. To any plan for forcing a union I should then have been, and I now am, totally opposed. You will, I hope, kindly publish this letter."

IN the Court of Queen's Bench on Thursday last—the Queen *v.* Diplock. In this case a rule had been obtained by the friends of Dr. Hardwicke, calling upon Dr. Diplock to show cause why a *quo warranto* should not issue to inquire by what authority he claimed to fill the office of coroner for West Middlesex. Mr. Gray, Q.C., and Mr. Beresford appeared for Dr. Diplock; Mr. Keane, Q.C., and Mr. Day appeared in support of the rule. Mr. Gray, without arguing the case, said he presumed the court would make the rule absolute, as the best mode of obtaining a scrutiny. The point with reference to bribery he understood was given up, but he suggested to the court whether a *quo warranto* would lie on the ground that the decision of the sheriff in a county court held purposely for the election of a coroner was final. The court were decidedly of opinion that it would, and made the rule absolute.

UNIVERSITY OF LONDON CONVOCATION.—The adjourned annual meeting of the convocation of this university was held on Tuesday, June 2, under the presidency of Dr. Storrar. Mr. W. S. Lean moved, "That it be an instruction to the annual committee, either in conjunction with the senate or separately, as may be judged most expedient, to take any steps that they may consider likely to aid in promoting the improvement of secondary education in schools; and especially to prepare and cause to be presented to both Houses of Parliament petitions praying for early legislation, having such improvement for its object; and that the chairman of convocation be authorised to sign those petitions on behalf of convocation." He urged that it was plain that schools which are thoroughly satisfactory are few in the extreme, and instanced many specific cases of the want of usefulness, and in fact of absolute abuse or alienation of important educational endowments. The latter cases were fortunately few, but the shortcomings were more numerous than desirable. The University of London, which rested entirely upon its standing in competitive examinations, had an especial interest and duty in enforcing and promoting secondary education, and the necessity of improved organization was clear.—Mr. W. Shaen seconded the resolution, strongly supporting the action and recommendations of the education commissioners, and contending that the university could not do better than give its active and cordial support to the scheme proposed by them.—Mr. Paget sup-

ported the resolution.—Mr. Hutton objected that the resolution did not express concurrence with the recommendations of the education commissioners, but embodied, in fact, an advocacy of progress without defining its direction.—The mover and seconder both agreed to a rider, to the effect that the steps to be so taken for the improvement of secondary education should be "in general accordance with the recommendations of the report of the schools inquiry commission." After discussion the resolution, as amended, was carried unanimously. Dr. P. H. Pye-Smith moved that the senate be requested to consider the expediency of discontinuing the gold medals now given at the M.D. and M.S. examinations; Dr. Broadbent seconded. After a discussion, in which it appeared that the number of medical graduates present were too few to argue the question fully, it was agreed, on the motion of Mr. Shaen, to proceed to the next motion. Dr. Taaffe moved (1.) "That in the opinion of convocation no person ought to be admitted to any degree unless he has previously studied at a college affiliated to the university," contending that this was a principle involving the real value of the university. It was no argument against this that the ancient Universities of Oxford and Cambridge were widening their doors, because the great principle was the collection of students in a common centre. He also moved (2.) "That in the opinion of convocation, middle-class examinations, similar to those of Oxford and Cambridge should be instituted in connection with the University of London, and that it be an instruction to the annual committee to take the subject into consideration." After discussion it was decided that the resolutions be put separately; and on the first resolution a tedious and lengthened controversy ensued, amidst expressions of impatience on the part of the members, as to whether such a movement was retrograde or otherwise, the mover contending amidst laughter that it was "retrograding in the right direction." The motion was almost unanimously negatived. On the second motion another lengthened discussion ensued, it being argued that there was no necessity to localise an examination which was now practically freely open; that it was unadvisable to introduce the system in London until the university had the means of guiding to some extent the schools which would produce the candidates for such examinations. In the course of the arguments the chairman stated that, in point of fact, the great advantage of the London University was that its system of proceeding to degrees earned solely by merit was in advance of the middle-class examinations. By permission of the house, Dr. Taaffe withdrew the motion. A proposal to adjourn the house, made for the third time, having been negatived, the Rev. A. Creak moved—"That the senate be requested to take steps for the establishment of courses of lectures or professorships in connection with the university." It was proposed to refer the subject to the annual committee to consider and report thereon, when a motion for adjournment was carried. Upon the resumption of the house, it was moved by Mr. B. W. Gibsone, seconded by Dr. Quain, and unanimously resolved—"That the annual committee be requested to draw up an address of congratulation to her Majesty the Queen on the escape of his Royal Highness the Duke of Edinburgh from assassination, and that the chairman be requested to sign and forward the same on behalf of convocation."

NOTICES TO CORRESPONDENTS.

Mr. RICHARD WALLACE will please receive our thanks.

J. G., Glasgow.—The point requires nice discrimination, as much depends upon the position of the party. There is no reason why medical men should attend the clergy and their families gratuitously, except it be in the case of one unbeneficed, or in charge of a very poor district. In large towns the distinction is seldom made or expected; but in small country towns and villages where the Doctor and Parson are generally found working together, it is somewhat different, and resolves itself into a question of feeling. Of course in midwifery and cases requiring operations, no clergyman would expect the medical man to go unpaid.

A CORRESPONDENT forwards us a circular, which is being sown broadcast throughout the country—of which the following is an extract—in the hope that its publication may influence the "Medical Council" shortly about to commence its sittings to adopt such measures which shall effectually stop such impostors, in their nefarious traffic on the nervous and unwary. Our readers will notice some slight deviation from the usual rule of quacks who *dub* themselves Dr. The *worthy* in the present case—whose address we have erased, modestly signs himself "Medicus."

"*Just Published, free to any address for two stamps,*

"A MEDICAL GUIDE, which contains full directions and prescriptions for the recovery of health and manhood; nervous debility, and all Private Diseases, can be cured with secrecy and safety, by following the directions in this book. Particulars are also given of a Specific for the cure of various female complaints, and Advice to Females on Important matters. Address Medicus, who may be consulted daily, in confidence. Established 30 years."

TESTIMONIAL TO DR. CHOWNE.

IT has been considered that, on the retirement of Dr. Chowne from the post of Physician to Charing-cross Hospital, he should, after his long and valuable services, receive a more substantial expression of the appreciation of his honourable and useful career than a mere vote of thanks.

It is therefore proposed that the Governors and friends of the Hospital be invited to subscribe to a fund to be raised for the purpose of presenting to him such a testimonial as may be determined upon.

Subscriptions will be received till the 1st of July, at the London Joint Stock Bank, 69, Pall-Mall, or at the Hospital.

ROBERT FEW, Treasurer.
HENRY WOOLCOTT, Hon. Sec.

THE LONDON SURGICAL HOME,

FOR Diseases and Accidents of Women; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. BAKER BROWN.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the LADY SUPERINTENDENT, 18, Stanley-terrace, Notting-hill, London, W.; or to Mr. BAKER BROWN, 136, Harley-street, London, W.

30th November, 1867.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, MANCHESTER.

WANTED an ASSISTANT MEDICAL OFFICER to the Dispensary Department, whose principal occupation is the visiting of the home patients. Salary £120. Qualifications and Testimonials to be addressed to the Hospital not later than the 22nd of June.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

—Founded 1788.—Incorporated by Royal Charter, 1864.—The Members are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 8th JULY next, at which Candidates for admission into the Society can be proposed. It is desirable that the Forms of Proposal be filled up and forwarded to the Secretary at least a week before the meeting. The Forms of Proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased members of not less than two years' standing. The Secretary attends at the Office every Wednesday and Friday from Four to Five o'clock.

J. B. BLACKETT, Secretary.

53, Berners-street, W., June 1, 1868.

LONDON NURSES' INSTITUTE,
42, South Audley-street, Grosvenor-square, W.

TRAINED NURSES (Medical, Surgical, Mental, and Monthly), can at all times be obtained from this Institute.

Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended,

Apply to the Manager or Matron. T. HAMILTON, Manager.

THE MEDICAL PROFESSION.

THE ALBERT LIFE ASSURANCE COMPANY. Established 1838—Annual Income £350,000, accepting healthy and invalid lives, is prepared to enter into special and liberal arrangements with members of the Medical Profession acting as private Agents of the Company.—Apply to the Secretary, FRANK EASUM, at the Chief Office, 7 Waterloo-place, Pall-Mall, London.

EXPORT OF THE CARLSBAD NATURAL MINERAL WATERS.

The wonderful natural properties of the Mineral Waters of Carlsbad are too well known to require commendation; they are a fact proved by the experience of many centuries. The waters can be used in the same way at home as at the Spring. The usual dose is One Bottle of Mineral Water each morning, taken at intervals of twenty minutes, either cold or warm, and after open-air exercise if practicable, or at home and in bed if necessary. To increase the aperient qualities of the bottled Carlsbad Waters, one teaspoonful of the SPRUDEL SALT should be added.

All orders for the MINERAL WATERS, SPRUDEL SALT, and SPRUDEL SOAP will be promptly executed at the Depots in all large towns, or direct by the Brunnen Nersendungs, direction of Heinrich Mattoni, Carlsbad, Bohemia.

Aerated Lithia Water.—Messrs. BLAKE,

SANDFORD, and BLAKE, are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. Garrod's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

Blake, Sandford, and Blake, Pharmaceutical Chemists, 47, Piccadilly.

CAUTION.—IN CHANCERY.

WRIGHT v. MARSHALL.

LIQUOR CARBONIS DETERGENS.

ON the 14th November, 1867, the Plaintiffs in the above cause obtained an injunction against the Defendant for infringing their (Plaintiffs') rights, as exclusive proprietors of the "LIQUOR CARBONIS DETERGENS." And Messrs W. V. WRIGHT and COMPANY hereby caution all persons against imitations of this article, whether colourable or otherwise; and they give Notice that parties manufacturing or circulating such imitations will instantly render themselves liable to legal proceedings.

NOTICE.—Messrs. W. V. WRIGHT and COMPANY having received a communication from the Commissioners of Inland Revenue to the effect that LIQUOR CARBONIS DETERGENS cannot be sold either for Dispensing, Export, or otherwise, without bearing the Government Stamp, they beg to inform the Profession and the Trade that in future it will be only sold in Bottles at 4s. 6d. and 11s. each, containing respectively 16 and 48 Fluid Ounces.

"SAPO CARBONIS DETERGENS" will be sold in the same manner and on the same terms as heretofore.

LIQUOR CARBONIS DETERGENS,

OR

Concentrated Alcoholic Solution of the Active Principles of Coal Tar.

A REMEDY FOR GANGRENOUS SORES, WOUNDS, ULCERS, AND ALL FETID DISCHARGES.

To prepare the Emulsion of Coal Tar, which is applicable to all domestic and therapeutic purposes,

Take Liquor Carbon. Detergens	...	...	1 part.
Water	...	...	4 parts. Mix.

More agitation of the mixture gives a durable Emulsion. By the addition of water, Emulsions at a strength varying from one-tenth to one-thousandth may be effected. Whatever the amount of water, the Tar remains suspended in a state of division equivalent to solution.

The qualitative analysis of this compound shows that it preserves all the virtues of the Tar, the active ingredients of which have been taken up by the alcohol—viz., the benzine, naphthaline, and carbolic acid—a powerful disinfectant. Further, the alcohol imparts to the preparation other properties which render this new compound applicable to the purposes of hygiene, medicine, and natural history.

Sold only in Bottles containing 16 *Fluid Ounces, at* 4*s.* 6*d.;* 48 *Ounces,* 11*s.*

PURE COAL TAR SOAP.

REGISTERED AS

TRADE MARK.

COMPOUNDED FROM OUR "LIQUOR CARBONIS DETERGENS."

By daily use of this Soap, infectious diseases are prevented, and a clear and healthy appearance imparted to the Skin.

Sold Retail by Chemists in Tablets at 6d. and 1s. each.

AND DIRECT FROM THE PROPRIETORS,

W. V. WRIGHT AND COMPANY,

WHOLESALE DRUGGISTS AND MANUFACTURING CHEMISTS,

Southwark-street, London, S.E. (Removed from 11, Old Fish-street).

CLINICAL LECTURE ON INSUFFICIENCY OF THE AORTIC VALVES.

By S. JACCOUD, M.D.,

PHYSICIAN TO THE HOSPITAL OF ST. ANTOINE, PARIS.

TRANSLATED BY JOHN COCKLE, M.D., M.A.

In the ward of St. Anne, there is a female patient whose case is of great interest. She must, formerly, have had an exceedingly robust constitution, since, although she is now sixty-seven years of age, and has been suffering for many years from an affection of the heart, her external appearance betrays no sign of organic degeneration, and her vital energy seems unimpaired. Nevertheless, this woman has been admitted into the hospital with a very serious combination of symptoms: violent palpitation, intense dyspnœa, general œdema of the lower extremities, and congestion of the lungs and liver. Such is an outline of the phenomena recently noted in her case. From this combination of symptoms, we cannot mistake an affection of the heart arrived at the stage of *asystole;* but a direct exploration of this organ can alone reveal the precise seat of the lesion, and, consequently, lead to a correct prognosis. Let us ascertain, then, what information it imparts. The hand applied over the region of the heart receives a moderate impulse, the extent of which transcends the normal limits of the præcordial region; there is, at the same time, a sensation imparted to it, as of a dense and compact body, moving *en masse*, with a certain amount of difficulty. Beyond this, no thrill is felt either at the base or apex of the heart. From these results of palpation, considerable hypertrophy of the heart may be affirmed, and this fact is directly proved by percussion. The upper limit of the base is barely changed, it corresponds to the superior border of the 3rd rib; but, the apex, depressed, and displaced outwards, beats at the level of the 7th rib, two fingers' breadth without the vertical mammary line. In the transverse direction, the enlargement is still more manifest, extending beyond the right lateral border of the sternum, as far as the mammary line upon this side.

Over the entire region of the base, auscultation readily detects a double murmur; the one—rude, rasping, prolonged and intense, corresponds to the systole of the heart, and usurps the period of the lesser pause; the other—shorter, softer, devoid of rasping character, and connected without interruption with the former, accurately coincides with the diastole. The murmurs then exist, one at the time of the first period, two other at that of the second. These murmurs, blended at the expense of the lesser pause, accurately represent a "to and fro" murmur, in which the "to" sound is much stronger than the "return" murmur. Upon gradually lowering the stethoscope, from the base to the apex of the sternum, these murmurs are found to weaken in proportion as the instrument is lowered; still, both are audible as far as the level of the third bone of the sternum; below this point, the second or diastolic murmur becomes inaudible, and, in its place, the normal second sound is heard. With respect to the first murmur, though still persisting, it is very weak, and does not prevent the normal first sound of the right ventricle from being heard. It must be borne in mind, that the base of the ensiform cartilage is the focus of auscultation for the right side of the heart. The murmurs are very audibly heard over the entire region of the base, though not of equal intensity at every part. The maximum site is, without doubt, at the most internal part of the 2nd right intercostal space; at this precise spot, nothing is audible but the double murmur; but, at the corresponding site upon the left side, along with the murmur, the normal tic-tac, two concussion sounds are heard. It is then very obvious, that the murmurs are loudest at the right side, and originate at the aortic focus; the normal tic-tac heard at the same time with them upon the left side, is that of the pulmonary artery.

When the apex is explored, by applying the stethoscope over the site corresponding to the impulse, a double murmur is also audible—one during the first, the other during the second period, but well divided by the lesser pause. In every case, then, gentlemen, in which isochronous murmurs are audible at the base and apex of the heart, this question arises: Does the double murmur at the apex exist *per se;* is it engendered at the spot, that is, in the left ventricle; or does it result simply from the descending transmission of very intense murmurs of the base? If the relative intensity of the sounds only was considered, we might incline to this latter inference; but this method of appreciation is far too coarse, and leads to error. It might very readily happen, as you may imagine, that a murmur at the apex, although originated in this point, may be weaker than a murmur at the base, and thus judged, the relative intensity of the murmurs would prove nothing. A more delicate method of exploration is needed, and I

recommend the following one to your notice:—Join, by a straight line, traced with the pen or dermographic crayon, the two *foci* where the murmurs are heard, that is to say, in the case before us, the second right intercostal space and the point of the sixth left space where the apex beats. Having done this, auscultate attentively the superior *focus*, in order to appreciate the murmurs there produced; then descend gradually, following with the stethoscope the line which you have traced. If the murmurs of the apex are only the propagation of those of the base, you will find them lessen, by degrees, as you quit the superior *focus*, and you arrive in this way at the extremity of your line, when you will again hear these murmurs, but weaker than at any other point of the course traversed. If, on the contrary, there really exist two *foci* of murmurs, one at the base and the other at the apex, the results of the test are altogether different. On quitting the superior focus you determine the progressive diminution of the murmurs just to a point more or less distant, but which generally corresponds to the median line of the sternum; parting from this point, the murmurs do not further diminish; on the contrary, they augment anew as far as the inferior focus, where they are louder than at any point of the second half of the tract. In the first case you have a gradually continuous diminution, so that there exists both a maximum and minimum focus; in the second case, you have, first, a gradual attenuation, then a progressive augmentation, so that there are two maxima *foci*—one above, the other below. The minimum point is between the two.

Musical notation permits us to figure these two conditions in a very exact manner. In order to indicate the variable intensity of sound, let a V shaped figure be drawn, the open end of which is turned towards the maximum, and the apex towards the weakest sound. The results of comparative auscultation in the two instances assumed are represented in Diagrams, on page 514.

This mode of application is easy in proportion to the size of the heart. The interval which separates the two *foci* is then more considerable, and the modification in respect to intensity of the force of the murmur is more marked. With a little experience, this method of exploration may be simplified by omitting the tracing of the conducting-line. In the case of our patient, there are obviously two maxima *foci*, and one minimum between the two, towards the mid-point of the sternum. We are already certain, from this fact, that the murmurs of the apex belong to the left ventricle—that is, to the mitral orifice. But, in order to form a judgment respecting a murmur, not only is its force to be considered, but note must also be taken of its tonality and timbre. A murmur, in propagating itself, loses force in proportion as it departs from the site of its production; but it retains, even to its complete extinction, its primary tonality and timbre. These are qualities that a diminution arising from the feebleness caused by distance cannot modify. A murmur engendered at the base and conducted to the apex, is here feeble; but it presents the same diatonic height, and the same timbre as the initial murmur. But in our particular example this is not what we find. The murmurs of the apex possess evidently a tonality higher than those of the base, and their timbre, duller and softer, contrasts with the clear and sonorous timbre of the superior murmurs.

The study of murmurs, separately, shows their respective individuality, and the character of the pulse will soon furnish us with a fresh proof, which, of itself, would be sufficient.

In possession, then, of these positive *data*:—considerable hypertrophy of the heart; "to-and-fro" murmur at the base, at the focus of auscultation of the aorta; two murmurs at the apex; and normal sounds of the right heart, we may already arrive at some conclusions, and formulate at least a portion of the diagnosis. There is, also, one among other conditions we may affirm, and that is insufficiency of the aortic orifice demonstrated by the diastolic murmur of the base. But there exists at the same spot a systolic murmur so connected with the former as to form a "to-and-fro" murmur, and the interpretation of the physical sign is not without difficulty. At all events, it cannot, like the former, be affirmed without discussion.

A murmur occupying the place of the first sound at the base, having its maximum at the *focus* of the aortic sounds, is the sign of contraction of the orifice of this artery, and when this murmur is connected with another during the time of the second normal sound forming the "to-and-fro" murmur, we infer that both aortic contraction and insufficiency co-exist, a double lesion, in truth, of very frequent occurrence. We must, however, bear well in mind that this double murmur has no pathognomonic value, and that the preceding inference is only authorized after examination.

If, indeed, the diastolic murmur, under the conditions indicated, certainly denotes an insufficiency of the orifice, the systolic murmur may depend either upon contraction of the orifice or upon a dilatation of the ascending aorta, combined with ætheromatous degeneration of its walls. These latter lesions are particularly observed in individuals of advanced age; you will, consequently, see that in the case of a patient 67 years of age, the description of this point of diagnosis becomes one of absolute necessity.

But the influence of aortic insufficiency upon the arterial system is not absolutely the same when the lesion is simple, and when it coincides with contraction of the orifice. In the first case, when a diastolic murmur alone exists at the base of the heart, two distinct murmurs are generally audible in the carotids, provided the aortic valves are so altered as not to produce a concussion sound; one of these murmurs prolonged, occurs at the moment of cardiac systole and arterial diastole. It is produced, according to Beau, by the want of relation which exists between the calibre of the artery and the superabundant wave projected by the hypertrophous left ventricle; the other, shorter, is heard at the moment of cardiac diastole, and arterial systole, and is produced by the propagation of the cardiac murmur. This double murmur may, by dexterous exploration, be heard in arteries remote from the heart, and, most markedly, in the femorals. When, however, the insufficiency is associated with contraction, however slight the latter may be, the phenomena become modified; there is then a double murmur at the base of the heart, but, generally, only one is heard in the carotids, and this, the first, or that which is systolic in relation to the heart and diastolic to that of the artery. This murmur is no longer the effect of the disproportioned wave, seeing that the contraction of the orifice counteracts its undue volume, but is simply the result of the propagation of the first cardiac murmur: it may be even absent, in which case auscultation of the carotids is mute. The second carotid murmur, that which before coincided with the diastole of the heart, and the systole of the artery, disappears under these conditions, because the transmission of the second cardiac murmur is not sufficiently intense to propagate it as far as the arteries of the neck. This failure of propagation has been correctly pointed out by A. Guyot, as constituting a distinctive sign between simple insufficiency and insufficiency with contraction.

In our patient, two very distinct murmurs are heard in the carotids, and this is a presumption against the existence of any marked contraction of the aortic orifice. And more than this, by adopting the following method, these murmurs may be still detected in the femoral artery. If the stethoscope is applied lightly over the artery, at the moment of diastole, only one membranous click is heard, caused by the sudden dilatation of its wall; increase, slightly, the pressure of the instrument, this click disappears and is replaced by murmur; increase still more the pressure, and, after the one murmur, a second, clearer, and extremely short, is heard. With reference to this mode of exploration of the peripheral arteries, I would remark, that it should not be practised with the ordinary stethoscope, its area is too large, and is badly adapted to the calibre of the arterial tube. Use, therefore, an instrument of narrow diameter, the opening of which scarcely exceeds

that of the carotid artery, and phenomena will be perceived which, without such precaution, would evade detection. The precise seat of cardiac murmurs also, in difficult cases, will be more readily appreciated by the use of this form of stethoscope.

The existence of a double murmur both in the carotid and femoral arteries, a very good sign of simple aortic insufficiency, pleads here against simultaneous contraction of the orifice ; but this is not all. The pulse of simple insufficiency possesses an aggregate of characters truly pathognomonic. The heart is hypertrophous, and the wave that it projects is too voluminous, composed, as it is, of the normal wave, augmented by the amount of blood which reflows into the ventricle through the chink left by the insufficiency. As a consequence, the pulse is full, large, occasionally even vibratile. In consequence of the increased impulse, it strikes the finger with the smartness of a spring which suddenly uncoils ; it becomes bounding : then, scarcely has the shock occurred, the arterial tension sinks to a minimum as a result of the reflux at the aortic orifice, the artery collapses, the pulse vanishes, is retrocedent. As the reflux of blood into the ventricle becomes increased by raising the superior extremities to a vertical position, it sometimes happens that, in this position, the rebound of the pulse remaining uncharged, the retrocession is much more marked. This phenomenon, however, is far from being constant. It may be readily conceived that these characters of the pulse may so diminish as nearly to disappear, should there exist, with the insufficiency, such an amount of contraction as to diminish, at the same time, the volume of the wave of blood and the force of the reflux. The pulse of our patient is perfectly bounding and retrocedent, it affords, consequently, two of the most important characters of simple insufficiency ; it is true that the amplitude of the pulse is not in relation with the bounding character of the artery, and that the rhythm of the stroke is very irregular, but these phenomena, entirely foreign to aortic insufficiency, will not be matter of surprise, if you consider that the case of this woman presents a double lesion of the mitral orifice, revealed by the two inferior murmurs, the individuality of which has been established. I affirm then, that if under such conditions the pulse retains the two fundamental characters of aortic insufficiency—bounding and sudden collapse, it is impossible to admit that contraction of the orifice adds its influence to that of the mitral lesion as to act, in a sense, inverse to that of the insufficiency. I shall defer, for the moment, the production of the sphygmographic tracings, as I do not wish to interrupt this demonstration.

So far, the positive signs of pure insufficiency are observed in our patient, and these symptoms, I repeat, acquire an importance of greater value, by virtue of the co-existence of mitral disease. On the other hand, one phenomenon fails which is frequent in isolated insufficiency —pulsation, visible at a distance, in the arteries of the neck and extremities. These rhythmic pulsations, which occasionally become a source of great distress, and sleeplessness, in consequence of the incessant agitation they induce in the cervical, and indeed the entire cephalic regions, result equally from the abnormal volume of the blood wave, and the excessive impulse of the heart. The entire absence of these pulsations in a case of aortic insufficiency, ought to induce suspicion of co-existing contraction of the orifice ; but, in our patient, the aortic orifice is not alone diseased, the mitral orifice presents alterations acting upon the wave of blood in the same manner as aortic contraction, and, since the phenomena, before noted, clearly demonstrate the non-existence of such contraction, it is natural to refer the absence of the characteristic arterial pulsations to the mitral disease.

While, then, the careful study of the differential signs of simple aortic insufficiency, and of insufficiency with contraction, leads to a denial of the existence of this latter condition in our patient—a positive sign confirms our conclusion and demonstrates the existence of dilatation of the ascending aorta. Percussion of the right sterno-clavicular region detects dulness extending from the sternal articulation of the 3rd rib to a finger's breadth below the sterno-clavicular articulation; the zone of dulness extends to two finger's-breadth at least, without the right border of the sternum, and is directly caused by the dilatation of the aorta. I do not think that this dilatation involves the transverse portion of the vessel, as I have vainly sought the sign pointed out by Guattani, as existing in such cases. According to this observer, whenever the arch proper of the aorta is dilated, on pressing the ends of the fingers deeply below the jugular fossa, the expansive impulse of the artery may be felt ; this phenomenon is never so marked as when, with dilatation, insufficiency co-exists, which augments the impulse. Nothing of the kind exists in the case before us, and as I have been enabled, on two or three occasions, to verify the sign indicated by Guattani, I infer, from its absence, that the dilatation is limited to the ascending portion of the vessel, or that the transverse portion is at least but very slightly involved.

With regard to the two murmurs at the apex, the first denotes, positively, the existence of mitral insufficiency, and I shall shortly prove to you that this condition is one of the secondary results of aortic insufficiency ; the diastolic murmur is the ordinary sign of contraction of the auriculo-ventricular orifice, but it may also simply result from excrescences around the orifice, or curtains of the valves—excrescences which engender vibrations in the column of blood causing murmur at the moment of its transit. Of these two changes the second seems to me, here, the most probable : the dilated hypertrophy of the left ventricle, an efficient cause of mitral insufficiency by the mechanical enlargement of the orifice that the valves ought to close, appears to me, in this particular case, difficult to reconcile with contraction of the same orifice ; the pulse again presents very marked irregularity, this sign, which is characteristic of mitral regurgitation, is seldom so marked when insufficiency is conjoined with contraction.

In summary, then, our patient suffers from simple aortic insufficiency, with dilatation and ætheromatous degeneration of the ascending aorta, and from mitral insufficiency, with excrescences around the orifice, and upon the curtains of the valves. Aortic insufficiency is the dominant lesion, the first link in the pathologic chain; it is this insufficiency which has caused the dilated hypertrophy of the left ventricle, and the consecutive incompetence of the corresponding orifice.

Let us now study the sphygmographic tracings. With Marey's instrument the three tracings before you were taken at intervals of several days (see Trace 1).

This tracing was obtained on the day of admission, at the time the accidents of *asystolic* were at their maximum; the pulse does not present one single character characteristic of aortic insufficiency ; it is one of mitral type evidenced by its weakness, irregularity, and intermittence. Feebleness is indicated by the diminished height of the ascensional line corresponding to arterial diastole, or cardiac systole; the irregularity is figured in a marked manner by the want of similarity between the curves, which represent single pulsations. Compare with these the pulsations numbered 1, 2, 3, 4, and you will be convinced upon this point; finally, the intermittence is shown by a line horizontal, or nearly so, which separates certain pulsations from the others. In that part of the trace which precedes the pulsation numbered 4, intermittence is shown in both pulsations.

With a trace so indicative of simple mitral lesion, nothing short of the exceptional clearness of the second murmur at the base would have induced the admission even of the existence of aortic insufficiency. Shortly after, however, matters became greatly modified. The patient had taken, at intervals of two days, two violent drastic purges, dry-cupping had been extensively applied for many days in succession to the base of the chest, and at the same time extract of bark, and a wine, rich in alcohol had been liberally administered. This plan of treatment, the very best that can be pursued in cases that

admit of no delay, caused free intestinal discharges, and copious diuresis; the œdema of the extremities diminished to a considerable extent; from the third day the dyspnœa was scarcely perceptible, sleep returned, and the cardiac contractions, sensible to the touch, had regained strength and regularity. The storm was appeased, and we could now, with surety, seek from the pulse a revelation of the exact condition of the heart. The reply was categorical, you read it as expressed in the second trace (see Trace 2).

The amplitude of the pulsations, or if you prefer the term, the height of the ascensional line, has nearly tripled. The pulse is constantly irregular, but even in this irregularity a real harmony exists, as shown by the exact periodic return of the abortive pulsations. Compare the beats which separate the pulsations numbered 1, 2, 3, and you will perceive that the intermediate series are alike in all particulars; they are composed of a pulsation with a long descent, changing shortly for intermittence, and then for two beats of perfect regularity. This periodic irregularity, according to Marey, is characteristic of senile change of the arteries. Finally, whilst the small pulsations, in crotchet form, denote the influence of the mitral lesion, you perceive in the regular pulsations, bracketed, the undoubted sign of aortic insufficiency. This sign is the abruptness and verticality of the ascensional line, instead of the rounded angle and oblique ascension of the normal pulse. This character could not be more clearly marked than in the first pulsation which follows the trailing beat. The pulse, so far from being at variance with the results of auscultation, here, confirms them thoroughly, and it indicates equally with the murmurs, the existence of the double lesion.

The third trace, taken some days later, is an accurate reproduction of the former, and this constancy in point of character is a guarantee of its semeiological value (see Trace 3).

I cannot permit this opportunity to escape without exhibiting to you the sphygmographic tracings of other cases of cardiac disease. By re-uniting the tracings which we have collected from our patients during the course of the session, I can demonstrate to you, *de visu*, the characters of the pulse as occurring in the principal organic diseases of the heart. This department of semeiology (thanks to the labours of Marey, who is in France, its originator), has now acquired a mathematical precision. In order that you may derive, from my demonstration, instruction really useful and positive, I shall be careful to approximate my types to those given by this skilful physiologist, and to point out the analogies and differences which they may present. My conclusions will thus be rendered more certain, and this somewhat dry examination be made really serviceable.

The traces analysed have afforded us an example of complex type—aortic and mitral insufficiency, with senile degeneration of the arteries. We have united and modified, one by the other, the sphygmographic characters of this triple lesion of the circulating system. I have now to exhibit a trace of almost pure aortic insufficiency, obtained from a man æt. 52, in St. Charles' Ward (see Trace 4).

Four peculiarities of equal importance characterize this form of pulse, viz., perfect regularity, amplitude of pulsation, verticality of the ascensional line and its small terminal crotchet. Whenever a sphygmographic trace presents all these characters well-marked, it is pathognomonic. It may be affirmed to be that of a patient suffering from aortic insufficiency, simple or nearly so. A comparison with one of the types depicted by Marey, will show you the fidelity of that I now exhibit (see Trace, Marey, Fig. 188).

Every point of detail is similar in these two traces save in one particular to which I direct your attention. In our patient the crotchet of the summit is not followed immediately by the oblique line of descent, but is separated by a small line, almost horizontal, termed, sphygmographically, the "level" of the curve. This level constitutes a good sign of senile degeneration of the arteries, and Marey does not assign to it any other signification. Our patient, however has certainly no such degeneration. On the other hand, the aortic insufficiency which, in his case, constitutes the dominant lesion, is combined with slight contraction of the orifice, and it is to this latter change that I attribute the small level which distinguishes the trace from one of pure simple insufficiency. I hesitate the less in this opinion since a similar level is observed in a trace of simple aortic obstruction that I shall exhibit to you. It was taken from a young man—senile degeneration, therefore, may be completely excluded. So far as my knowledge extends, Marey has not pointed out the influence of aortic obstructive disease in the formation of this level. He has, nevertheless, depicted it. The two following traces which he furnishes as examples of aortic insufficiency with obstruction, leave no doubt in the matter; he omits, however, the age of the patients (see Figs. 191 and 193, Marey).

Of the four characters accorded to the pulse of simple aortic insufficiency, two are of more constant occurrence than the others, viz., regularity and verticality of ascent. If the patient is weak, there may occur no marked amplitude of the pulse; consequently, the length of the line of ascent may not be greater than ordinary; the characteristic crotchet may also be absent under these circumstances; but the two remaining characters remain, for these are fundamental. These peculiarities are well-shown in the following trace, obtained from a young woman suffering from simple aortic insufficiency. Seven months ago this patient was seized with slight hemiphlegia and aphasia, caused by cerebral embolism. The cerebral disease persists, and, at the time the trace was taken, the patient was in a state of very great debility (see Trace 5).

The typical pulse of aortic insufficiency may, as we have seen, become modified, both by the general conditions of the individual, and by coincident lesions of the heart, whether mitral insufficiency or aortic obstruction. The modification is not the less remarkable when defective closure of the aortic valves is complicated with insufficiency of the tricuspid orifice. We have met with an example of this rare complication in a man æt. 44. The pulse no longer presents either the amplitude or the characteristic crotchet; the verticality still exists but does not appear through all the pulsations, and this result takes from the trace its perfect regularity, but the irregularity thus produced in nowise resembles the disturbances pathognomonic of the mitral pulse. (*Vide* traces 1, 2, 3, 11.) (See Trace 6.)

Marey has given two traces of the radial pulse in tricuspid insufficiency, and notwithstanding the difference resulting from the absence of coincident aortic insufficiency, it is easy to detect, between these traces and the preceding, a relationship which connects them (see Figs. 214 and 215, Marey).

The weakest pulsations of our trace possess a curve perfectly resembling those of Fig. 214, and the manner of succession of the large and small pulsations, calls to mind the ryhthm of the trace 215.

(To be continued.)

Original Communications.

ON DISLOCATION AND ABNORMAL MOBILITY OF JOINTS, THE RESULT OF CHRONIC RHEUMATIC ARTHRITIS.

By ROBERT ADAMS, M.D.

(Read at the meeting of the Surgical Society of Ireland, on the 24th of April, 1868.)

LET me now, gentlemen, redeem the pledge I made in my inaugural address as President of this Society, that I would subject to its notice some remarkable examples of external disease, authenticated by casts and drawings.

The first case I shall bring forward is one of dislocation and extraordinary mobility of some of the articulations of a patient, who laboured under the disease termed chronic rheumatic arthritis, and from the continued effects of this

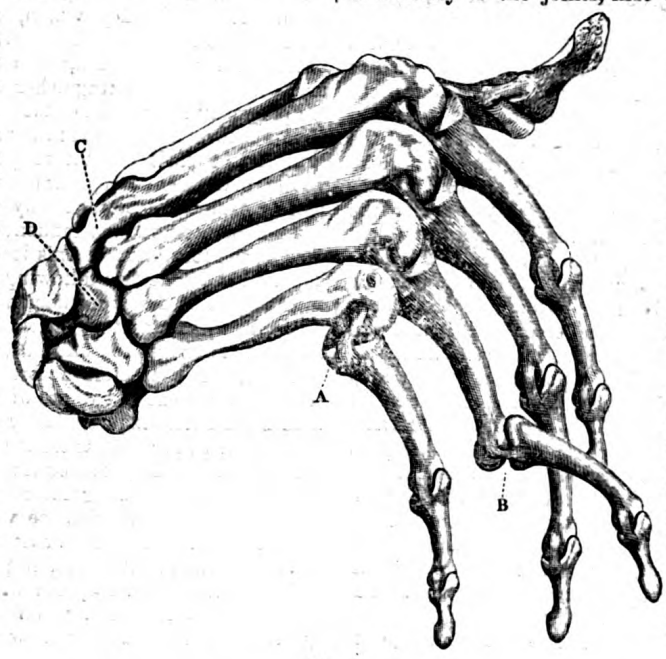
disease there can be no doubt but that these remarkable dislocations resulted.

served that the joints become *distorted* by it, and *probably* in bad and *inveterate* cases even *dislocated*."

The distortion, as the disease increases, becomes self-evident in almost every case, and we can now adduce abundant evidence to prove that the joints, both small and large, become, under the influence of this disease, sometimes partially and sometimes completely dislocated.

There is something peculiar in these dislocations, they evidently do not occur without there being previous disintegration and disorganization of the articular textures; and yet the abnormal mobility which accompanies and follows this disintegration of the structures of the

Dr. Haygarth, of Bath, who, under the denomination of nodosity of the joints, first described this disease, ob-



joints, is attended with but little pain, or increased swelling, or inflammation.

Luxation of the bones of the fingers, I have elsewhere stated, are frequently the consequence of chronic rheumatic arthritis—the most usual of these I have seen is that of the first phalanx (A, Fig. 1) of the little finger towards the palm, from the head of its metacarpal bone.

Cruveilhier has described and delineated a case in which *all the* phalanges of the fingers were thus dislocated towards the palmar surface of the hand. — Livraison xxxiv. Planche (see Note 1).

The median joints also of some of the fingers are occasionally dislocated. (See Fig. 1, B.)

Fig. 1.

Effects of chronic rheumatic arthritis on the right hand, as exhibited on post-mortem examination, upwards of eleven years after the commencement of the disease. A, The base of the first phalanx of the little finger luxated forwards. B, Luxation of the second phalanx of the ring finger, at the median joint, backwards.

In my treatise on chronic rheumatic arthritis, I have mentioned that partial dislocations of the shoulder were frequently found to be the result of this disease. Partial and complete dislocations of the patella also occur as a consequence of it. But laying aside generalities as to these luxations, I will at once introduce to your notice a case of a patient, who had chronic rheumatic arthritis in almost all his joints, small and large, and *in three of these last*, namely, two shoulder-joints and one knee-joint, complete dislocation and abnormal mobility of the bones composing these articulations existed.

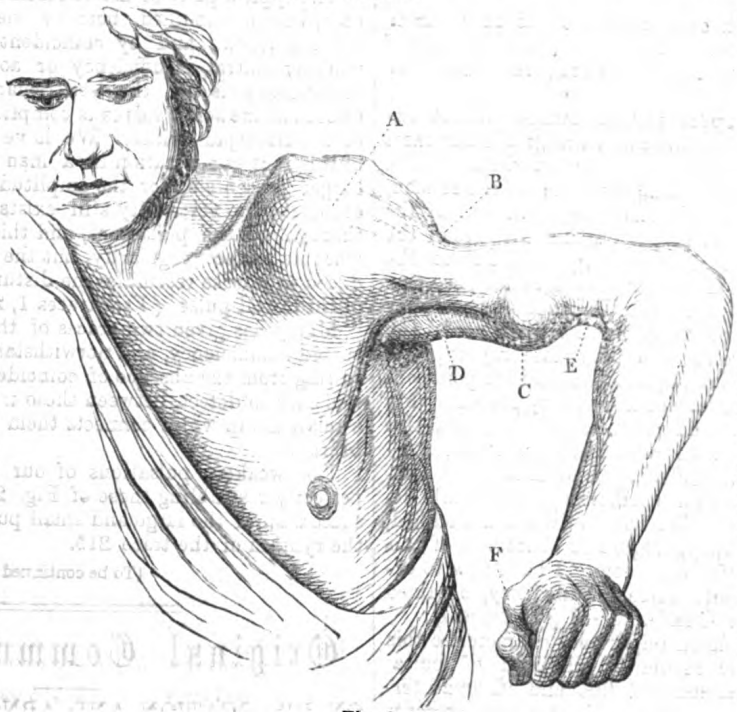


Fig. 2.

Chronic rheumatic arthritis of the shoulder, with abnormal mobility of the joint.

CASE.—*Chronic Rheumatic Arthritis of both Shoulder-joints and of the left Knee-joint, with remarkable Abnormal Mobility of these three Articulations in the same patient. The result of the Disease.*

J. Stafford, aged 48, cabinet-maker, was admitted into the Richmond Hospital, on the 2nd September, 1856. The notes of this case, taken at the time of his admission, are as follows: he is a pale, rather delicate-looking man, who seems to have led a laborious life.

As we stand before the patient and view his left shoulder, we observe it is much altered from its normal form. Its appearance, however, is very variable.

When the patient keeps his elbow to his side the stump of the shoulder presents a rounded appearance, which is due to muscular development, but to the existence in the interior of the shoulder-joint of a large quantity of synovial fluid. When he has raised his left elbow from his side (Fig. 2), we are at once struck with the abnormal appearance the arm presents. Just where the deltoid muscle is inserted into the humerus, a remarkable angle is formed, the sinus, B, of which looks upwards and outwards, and presents such an appearance as the humerus does when the head of this bone is dislocated from an accident into the axilla. The patient, as he moves his elbow from his side, feels the rubbing of the bony surfaces on each other; and if the surgeon introduce his fingers high up into the hollow of the axillary cavity, and at the same moment still further abduct the elbow from the side, the head of the humerus is plainly felt by the fingers to be really dislocated into the axilla. If the elbow be first drawn backwards, and an impulse be given to the shaft forwards, then the head of the bone can be thrown very much towards the clavicle, and be made to present a more obvious tumour in front under the pectoral muscle, than downwards into the axilla, exhibiting not only the semblance to, but the reality of, the luxation forwards and inwards. When the head of the humerus is thus dislocated

forwards, and rotation is communicated to the arm, a remarkable crepitation is perceived, while the head of the bone is felt to obey all the motions given to the shaft.

The region of the shoulder presents to the view a sufficiently plump and rounded appearance, and in this respect only, differs in its aspect from that which this region assumes when accidental luxation has occurred. In other words, the angular appearance of the shoulder, at the acromion, usual in accidental luxation, is absent, because the space beneath the acromion, abandoned by the head of the bone, is filled up with an inordinate quantity of synovial fluid, which distends the capsular ligament. As the patient can at will produce the dislocation in question, so also can he voluntarily, or by the exertion of the muscles of the shoulder alone, return the head of the bone back to the centre of the glenoid cavity; and, indeed, I believe the ordinary movements he has been in the habit of performing at his work, so far as the articulation of the left shoulder is concerned, consist altogether in the continual change of place of the head of the humerus from the glenoid cavity into the axilla, and back again from this space to its socket. The patient says that the shoulder-joint feels remarkably loose, but that he can perform all the "underhand" movements of the upper extremity perfectly, and that he could earn his bread at his trade, were it not for the sense of weakness and really relaxed condition of his left knee, which prevents him standing at his bench at his work.

When we take hold of the elbow of the patient, and pull the humerus downwards in the direction of its long axis, we find that the bone can be made to descend from the glenoid cavity for the extent of one inch. The capsular ligament must therefore be longer and wider than natural to admit of all this change of position of the head of the humerus.

It may, I think, also be assumed that the margin, too, of the original glenoid cavity is, probably, now so fashioned that its edge does not afford the same obstacle it ordinarily does to the exit and the return of the head bone again to its place.

The *intra-articular* portion of the tendon of the biceps is in this case, no doubt, as it ordinarily is in this disease, destroyed; and hence it is that the movements of the head of the humerus are unrestrained in the widened capsular ligament, and that the luxations mentioned are permitted.

Then, as to the *extra-articular* portion of the tendon of the muscle, it is seen to form an abnormal line (Fig. 2, D), extending from beneath the fold of the pectoral muscle for two inches before it reaches the upper margin of the belly of the biceps, which is smaller, shorter, and placed lower down than natural; and when, by the will of the patient, this muscle is thrown into action, it forms a prominent rounded tumour, C, about the size of an orange. On these occasions, also, we notice, descending from the lowest part of the muscle, another prominent line, E, which appears to be the lower tendon of the biceps passing to its insertion into the radius.

It was also noted at the period of his first admission into hospital, 1856, that his left knee-joint is much swollen from effusion into the synovial sac. The swelling extends upwards on the front of the thigh, and there is also a remarkable fluctuating swelling posteriorly in the popliteal space, as in a case of chronic rheumatic arthritis I have already published (see Atlas plate, Fig. 9). He cannot for the last three months stand on this limb. Whenever he throws the weight of his body on it there is a yielding of the knee, which becomes instantaneously bowed outwards. When we grasp the leg above the ankle we can easily communicate to the knee-joint an abnormal movement of abduction and adduction. The patient states that for the last two years he has felt the left knee-joint very weak, and that latterly it has become swollen; yet that he used to walk about, and even work at his trade, until about three months ago, when walking through the street, his left knee gave way suddenly under him, as if something had been ruptured and broken within the joint, and that ever since this occurrence he has been unable to walk, or even stand, without assistance. The swelling of the joint has been truly chronic. Even when the sudden giving way of the knee announced that some rupture of the ligamentous structure within the joint had occurred, on this occasion there was no pain felt at the moment, nor did any increase of the swelling follow the accident. The patella is very large, measuring nearly three inches transversely, and can be moved about as if very loosely connected by its ligament to the tibia; it seems to float, as it were, on the surface of the synovial effusion existing within the joint. The other usual symptoms of chronic rheumatic arthritis exist, cringing noises are heard on moving the joint, and when we sink our fingers as deep as can be done into the cavity of the swollen knee-joint, we can detect some few foreign bodies in its interior; when we press the bones of the leg up against the condyles of the femur, in the direction of the long axis of the limb, or even percuss the heel in the same direction, we cause the patient no sense of uneasiness.

Such is the *abnormal* mobility in the lateral directions, that we fear a complete luxation of the bones is imminent.

OBSERVATIONS.

Treatment.—In such an advanced case of chronic rheumatic arthritis of the knee and shoulder-joints, as described in the account given of the foregoing case, it did not appear to me that much benefit was to be expected to be derived from the adoption of any special line of medical treatment carried on within the walls of an hospital.

The patient did not complain in any of the affected joints of the upper extremities, and, under all these circumstances, he was but for a very short time detained in the institution.

It might occur to some to suggest that a system might be adopted relative to the local treatment of the loose condition of the left knee-joint in this case, with the hope of bringing about an anchylosis of this articulation, but I was myself without a hope that any line of treatment could be devised in this case which could bring about a permanent stiffness of the knee-joint, because this articulation was not only inordinately free on flexion, but had abnormal lateral motions of adduction and abduction, so that I had not the slightest confidence in any measure which we could adopt as likely to induce anchylosis, more particularly as I have always remarked that the joints in this disease were not disposed to anchylosis.

The principal indication therefore appeared to me to be to provide for him such a mechanical appliance as might best counteract, when worn on the limb, the abnormal mobility of the knee. The instrument which seemed to me best calculated to fulfil this indication, was one of these not uncommonly used to support the knee in cases in which this joint has been observed to be deformed, leaning too much outwards or inwards, such an instrument, Fig. 31, as delineated in the valuable work of Bonnet;[1] but in this that I had caused to be constructed, the hinge-joint at the knee has been suppressed, as our object was to render the limb stiff and firm, so that the patient might be able to stand at his bench.

This instrument was composed of two steel-rods, which corresponded respectively to the outer and inner sides of the limb. (see Fig. 3.) These lateral rods were continuous below, forming a loop or stirrup, the basis of which traversed the sole of a boot, which was laced round the ankle. The outer steel-rod was joined above, transversely, by a leathern girdle, which was strapped around the waist: a hinge-joint in this outer rod, allowing of flexion of the thigh, corresponded to the situation of the hip-joint; while below, in both of these lateral supporters, corresponding to the situation of the ankle, a hinge-joint also existed. Two transverse bars—the one placed behind the centre of the thigh, the other behind the calf of the leg—well padded, and covered with chamois leather, half encircled the limb pos-

1 Traité de Therapeutique des Maladies Articulaires. Par A. Bonnet. Page 345.

teriorly in these two situations, while the circle was completed by leathern straps buckled in front of the leg and thigh.

In this apparatus the limb was secured, and all motion of the knee-joint prevented, while the two hinge-joints existing in the apparatus — one at the level of the hip, and the other at the ankle — allowed of the necessary movements in walking.

Stafford appeared this morning, January 15, 1857, at the Richmond Hospital, with the above-mentioned apparatus applied, and he stated that he derived the greatest advantage from the use of it, as it enabled him to stand and work at his bench for several hours a day, and it was by its aid he walked from his residence this morning, two miles distant, to the hospital.

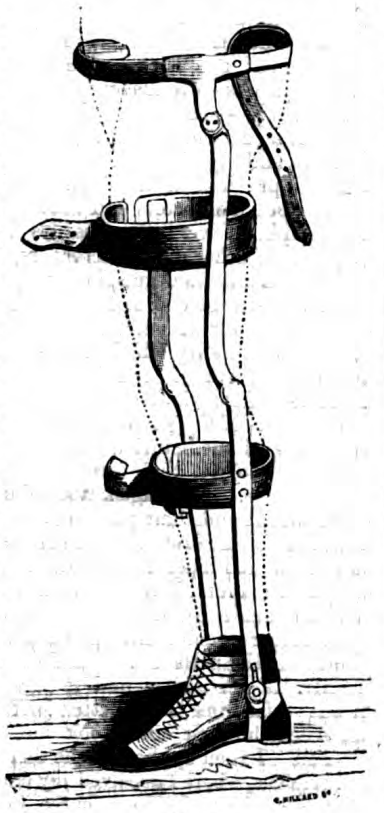

Fig. 3.
Apparatus for the support of the knee-joint, applied in the case of Stafford.

We should, however, here also mention, that in addition to the steel apparatus (Fig 3) the limb was included, from the trochanter major to the ankle, in a case made of sole leather, enveloping closely the thigh, knee-joint, and leg, united in front by buckles and straps.

(To be continued.)

HISTORICAL SKETCH
OF THE
DISMEMBERMENT OF PHARMACY FROM PHYSIC.

By M. DONOVAN, M.R.I.A.,
HON. MEMBER OF THE PHILADELPHIA COLLEGE OF PHARMACY.

(Continued from page 494.)

THE rebellion breaking out soon after, the King's order in Council was not enforced; and, notwithstanding this contemplated dissolution, the Society of Apothecaries still continued to exist, but merely as a trading corporation, and one of the city companies. In the time of Charles II. an attempt was made by the College to restore the old practice of causing the patient to send for the articles required, and compounding or dividing them at home; but the attempt failed. For, the power and influence of the apothecaries daily increasing, the physicians had no alternative but to be left without business, or to comport themselves "in a professional manner" towards the apothecaries. There was at that time a term well understood of "going snips" with the apothecary, which meant a certain percentage paid by him to the physician on all prescriptions written by the latter; and this practice, not a very creditable one to either party, tended still more to advance the influence and power of the apothecaries. Guy Patin, the censor of his age, says the apothecaries of England (1642) are great "coupeurs de bourses," and the physicians aid them (Let. Choisies ii., 349); but Guy's tongue is no slander, for he says that Sir Theodore Mayerne was "un grand charlatan." For the last century these practices, if they ever existed, are altogether unknown in the British isles.

The apothecaries, very properly emulous of a public acknowledgment of their services, petitioned Parliament to exempt them, like the physicians, and for the same reasons from serving in the offices of constables, scavengers, and other parish offices; and endeavoured to obtain a clause giving them legal permission "to administer physic to the poor." But although by the Act of 6, William III. (1694), they obtained the exemption required, they failed in the effort to obtain a license to practice. The physicians exasperated by this new attempt at encroachment, determined on a measure of retaliation, and (1696) adopted a resolution in the College to raise a fund for the supply of medicines to the poor at a reduced rate. In a short time they enrolled forty-six subscribers at ten pounds each, amongst whom was Sir Hans Sloane, afterwards so great a benefactor to the apothecaries. A grant of the College laboratory, which had long lain neglected, was made them for the preparation of their medicines, and in half a year the dispensary was opened at the College in Warwick-lane, and soon after two others in different localities. A pamphlet published about that time (Brit. Mus.) declares that the dispensaries charged eightpence or ninepence in the shilling less than the apothecaries, and gives a list of apothecaries prices—viz., a cordial bolus, one shilling and sixpence, by some two shillings and sixpence, it being really worth twopence. A cordial draught one shilling and sixpence, although dear at threepence. A vomit one shilling and sixpence or two shillings and sixpence, worth one or two pence. A quart apozem, worth threepence, cost two shillings and sixpence, unless the apothecary chose to divide it into eight draughts and charge it at eight shillings; or one ounce of a powder ordered by the physician, dear at one shilling, the apothecary by officiously dividing it into sixteen papers would make it worth eight shillings.

In a document published in London (1686) by the College of Physicians, in which they set forth their powers, amongst other unseemly manifestations of irritation they say, that the fellows were sworn "to do all things for vindicating and perpetuating physic, so that a profession be not invaded by the vulgar (meaning no doubt the apothecary) which hath been the usual support of the younger sons of the gentry of this kingdom" (Appendix to be statutes 1696). Such a self-glorification as this last the London College of Physicians did not blush to avow; and it is just in character with the following by-law passed ten years afterwards:—"No surgeon, apothecary, or any person that had been apprenticed to a trade shall be admitted into the order of candidates or fellows." We blush to find the same sentiment professed even by the Stagyrite, who says, "For it is not possible for him to apply himself to the study and practice of virtue who lives the life of a sordid mechanic or hireling"—(Taylor's Aristotle.)

The dispensaries of the College went on prosperously for some time. In one of their publications they declared that, on comparing the number of their prescriptions with the cost of them, they found that medicines had been, on the average, sold to the public at three half-pence per dose—a price very different from that charged by the apothecaries. But as the physicians had sold medicines at so low a rate, the apothecaries determined on selling advice at a still lower; and at length erected a dispensary of their own, where medicine and attendance would be supplied to each individual of a family at the rate of two shillings per quarter, and at the patient's own residence without additional charge (see Prospectus of the College, 1732).

The apothecaries, watchful for an opportunity of retorting the charge of extortion, brought one Dr. Tennant, before the College, who had prescribed for a servant two pills for which he had twelve shillings, and at night a little syrup, for which he got twenty shillings, and another twelve shillings. In another case, the doctor charged six shillings

for a pill which operated forty times as an emetic, and thirty times as a purgative (Goodall's His. Acc.)

To curtail the apothecary's profits, and to compel him to relinquish the practice of expensive subdivisions of medicines, the physicians, under pretence of guarding against the alleged mistakes made in translating the Latin directions, enacted a by-law (1696) that no member of the College shall write any Latin directions for the use of a medicine, but shall order it to be marked with such titles as will distinguish it, and shall leave directions for the use of it in English with the patient, under twenty shillings penalty. Thus, the patient knew what he ought to receive.

The dispensary occasionally compounded for the rich as well as for the poor under the flimsy pretext of guarding against adulterations and substitutions. They also kept secret formulæ to prevent apothecaries from boasting that they knew all the medicines that physicians used, and therefore could employ them. The apothecaries revenged themselves by preventing, when they could, any physician from being called in who had any connection with the dispensary, and those who had not found their account in the friendship of the apothecaries. The latter circulated a list of the physicians with a mark affixed to the names of those that were not to be countenanced; they charged higher prices for medicines prescribed by a physician, and we find it stated in a pamphlet dated 1702, entitled "Present State of the Practice of Physic," that on one such occasion the apothecary charged two and sixpence each for boluses. An apothecary even insulted a physician in a public room because the latter, in treating a patient, had prescribed so little medicine. A pamphlet of 1707 says that some physicians opposed the dispensaries, crouched to the apothecaries, concealed their blunders, and entered into collusion with them to enhance their bills, because they found it impossible to get into practice if opposed by them (Brit. Mus.) The physicians charged the apothecaries with ingratitude, and said that they owed any little knowledge they possessed to them, and that they had always been their servants, attending them in the sick-room to take their directions. The apothecaries replied that the physicians themselves knew nothing of the treatment of diseases, but what they learned from antiquated books, as they had no opportunity left them of learning modern practice ("Calamity of the English in Sickness," 1707). The medical war, as it was called, was spoken of in every company, and was celebrated in the well-known poem, "The Dispensary" by Dr. Garth.

The physicians, enraged with these attacks on their professional competency, retorted this charge of ignorance on the apothecaries. A pamphlet "On the Usefulness of Dispensaries, &c., 1702," thus describes the education of the "apothecary doctors," as they were called:—"At a grammar school he has learned to construe a little Latin; it is very rare to have a smattering of Greek; he is apprenticed; is set to the pestle and mortar, and to run of errands. After a year or two, he begins to make up prescriptions and carries home the medicine to the patient, and is thus employed until his time is run out. Hence he has read nothing and knows nothing of disease, and has forgotten his Latin. Thus accomplished, he sets up as a general practitioner, or apothecary doctor."

Meanwhile, the number of these increased. In 1640 the number in London and Westminster was 100; in 1700 they were at least 337 within the bills of mortality, but physicians estimated them at 1000, the total number of the College being 103; that is ten apothecaries to one physician, although in well-regulated cities of other countries the ratio was just the reverse, the number being restricted to one apothecary to ten physicians. At this period Copenhagen had but twelve apothecaries; Hamburgh had but one apothecary's shop; Stockholm but four or five; Paris 51.

The apothecaries of London themselves loudly complained of their numbers, declaring that their stock of medicines, which the prolixity of the pharmacopœia compelled them to keep, lay spoiling on their shelves, owing to the excessive division of the whole quantity of medical business to be done. ("Bellum Medicinale" and "Present State of Physic and Surgery," 1701).

At this time the whole medical profession was in a state of the utmost confusion. The physicians were divided into two parties—the dispensary doctors and the anti-dispensary party—each abused the other, impugning motives and blaming actions. The surgeon quietly trenched on the physician and apothecary; the apothecary resolutely invaded the province of the surgeon and physician; the apothecaries became doctors and doctors apothecaries. Malignant pamphlets were the missiles which the belligerents flung at each other; the doctors represented the apothecaries as ignorant and grasping cheats; and the apothecaries represented the doctors as self-sufficient monopolists. The apothecaries, having successfully invaded the province of the physician, relinquished their own, and no longer prepared either chemicals or galenicals, but bought them from wholesale dealers who merely studied their profits (Ibid).

In defiance of the powers of the college, the apothecaries still practised medicine, at first on sufferance, but afterwards more boldly, their gradual encroachments exciting little jealousy. At length, the college finding their province invaded and their powers defied, determined to try the efficacy of the law in confining the apothecaries to their real duties. A proper opportunity soon occurred. In 1704, one Seal, a butcher, being sick, sent to an apothecary named Rose, who made up for him several medicines as proper for his distemper—such is the apothecaries statement; but the following is the patient's:—"I, John Seal, being sick, had this Mr. Rose's advice and medicine for a year together, but was so far from being better for them that I was worse than when he first undertook me, and at an expense of near £50. I then applied to the dispensary at the College of Physicians, where I received my cure in about six weeks, for less than forty shillings charge in medicine." On the strength of Seal's statement, the case was brought to trial in the Queen's Bench (Anne). The verdict was argued by counsel at bar, when the judges unanimously agreed that the facts did amount to practising physic within the meaning of the statute, and that the proper business of an apothecary is to compound the prescriptions of physicians. This decision, far from subduing the resolute apothecary, he brought his case, by writ of error, to the House of Lords, on the ground that this decision would ruin the trade of the apothecaries, that the monopoly on the part of the physicians amounted to a tax on the nobility and gentry, who on the most trivial occasions can have no assistance for their servants without giving a fee to one of the college. The judgment in the Queen's Bench was reversed.

From this time the practice of medicine was chiefly in the hands of the apothecaries. The physicians declared that the apothecaries never called them until the patient's case was hopeless, and as a protection for themselves against indictment in case of the patient's death.

Taking leave of these professional squabbles in Great Britain, let us take a passing glance at the state of medical affairs in some other countries of Europe.

In Italy, the medical profession had for several centuries been under a strict and minute system of supervision and discipline. So far back as the reign of Frederick II., Emperor of the Romans, an edict was issued by that monarch, date 1237, which for minuteness of detail in the regulation of every particular that related to medicine had never been equalled. In 1685, it was adopted as the basis of an edict by Frederick William of Prussia, and rendered much more extensive in its provisions and more applicable to the altered condition of society. As a kind of medical curiosity, I give the substance of both.

The edict forbade any one to study medicine unless he had studied logic for three years; he might then proceed to the study of medicine, which he was to continue for five years, including surgery; and after being examined, he was qualified to practise. He shall swear that should it come to his knowledge that any apothecary (confectionarius) compounds

unfaithfully, he shall denounce him to the Senate. He shall swear that he will give his advice gratis to the poor—"Iste medicus visitabit ægrotos suos ad minus bis in die ad requisitionem infirmi : semel nocte : a quo non recipiet per diem, si pro eo non egrediatur civitatem vel castrum, ultra dimidium tarrenum (a Neapolitan or African coin-Spelman) auri. Ab infirmo autem quem extra civitatem visitat, non recipiet per diem ultra tres tarrenos cum expensis infirmi, vel ultra 4 tarrenos cum expensis suis." He shall not keep company with apothecaries, nor make bargains for cures, nor keep a shop. The apothecaries shall be bound by oath that all confections (compound medicines) shall be prepared according to prescription without fraud. He may charge for medicines, not kept in store beyond a year from the time of purchase, so as to profit 3 tarreni per pound ; for articles kept more than a year, 3 tarreni per ounce. The appointment of sworn examiners of apothecaries' shops then follows (Bulæi Hist. Univers, Par. III., 158).

The edict of Frederick William, which embodied and added to the foregoing, dated 1685, was intended to regulate all departments of the profession of medicine : it treated of physicians, apothecaries, surgeons, barbers, bathers, oculists, teeth-drawers, midwives, quacks, vagabonds, and cheats. Its chief provisions were as follows : The sale of medicines was strictly confined to apothecaries. In return for this monopoly, the discipline of apothecaries and their apprentices was minutely detailed. The master shall see that his apprentice says his prayers every night and morning. He shall take care of fire and candles in his laboratory and shop. He shall see that prescriptions marked *statim* or *cito* shall be immediately executed. He shall take an oath to the effect that he will not exceed the charges marked in the price-list authorised by the edict, that he will faithfully prepare physicians' prescriptions, and not substitute nor use false weights and measures ; that he will abstain from visiting and treating the sick ; and, particularly, that he will not sell purgatives, vomits, strong medicines, opiates, or poison, without the knowledge and consent of a physician.

The apothecary's apprentice is instructed by the royal edict to get up early every morning, to say his prayers with care, to light the laboratory fire, open his shop in time, keep it clean, and wash all the utensils any time they are used ; he shall abstain from drunkenness and gambling ; before he is bound he shall be examined by the College of Physicians as to fitness ; he must be of honest parents ; and shall compound nothing of consequence until he has been an apprentice four years.

Apothecaries, surgeons, and barbers, were ordered to be examined by the College of Physicians of Berlin, and the apothecary shops are to be examined by the College. The surgeons are not to undertake internal cures, they shall always take a physician for his advice in dangerous cases. Grocers, chemists, distillers, confectioners, perfumers shall neither prepare nor sell drugs, for this is the province of the apothecary. The bath-keepers shall not give internal remedies, nor encroach on physicians, surgeons, or apothecaries. Oculists, operators, midwives, and teeth-drawers, must be examined by the College. Medical students, surgeons, and midwives, must attend anatomical demonstrations.

Another edict, dated 1693, gave a list of the charges for physicians' visits, consultations, &c., a price-list for surgeons' operations, as trepaning, setting fractures, bleeding, taking off a leg or an arm ; as also a price-list for all medicine sold by apothecaries.

These edicts were to take effect in the southern parts of Italy ; in that country pharmacy was conducted with a degree of elegance never surpassed. The traveller Misson states that in a celebrated pharmaceutical establishment at Loretto, he was shown 145 earthern vessels which were highly esteemed, as they were believed to be painted by Raphael : on the largest were represented St. Paul and the four Evangelists, and on the rest the histories of saints and subjects from Ovid—an unfortunate association (Travels). Others have reported still more splendid embellishments of this celebrated establishment. In France, also, some beautiful pharmaceutical repositories were to be seen.

In Paris (1660) the surgeons and barbers had been incorporated into a community, and placed under the jurisdiction of the State barber, who enjoyed the privilege of shaving the king (Daubigny). The clergy and the monks often officiated in the shaving department of surgery ; and the clergy undertook the treatment of diseases to such an extent that their clerical duties were often neglected, until it became necessary to interdict their practice by royal authority. Monks and friars occasionally sold medicines, but were prevented by an edict in 1707. It was not until the time of Louis XVI. that the French apothecaries were separated from their unfortunate union with the grocers ; previously to this, the apothecaries had sought and obtained the privilege of selling hams. There was a time during the reign of King John of France (1359) when an edict was issued which forbade any one to practise pharmacy unless he knew how to read.

In the foregoing sketches I have abstained from any allusions to Irish pharmacy, aware that a succinct account of all that is curious or useful in it had been already given in a "History of Pharmacy in Ireland," by Dr. William D. Moore, M.R.I.A., &c.

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

OPERATIONS PERFORMED ON JUNE 6TH.

By Mr. CROLY.

Case 1.—AMPUTATION OF THE PENIS FOR CANCER INVOLVING ALMOST THE ENTIRE ORGAN.

P. K., aged 60 years, married, father of three children, by occupation a carpenter, residing in the County Kilkenny, was recommended to Mr. Croly for operation, and was admitted into hospital on the 1st of June.

History.—He enjoyed excellent health until three years ago, when he got a fall on a beam of timber, and struck the penis. Some blood escaped, at the time of the injury, from beneath the prepuce. The patient had not congenital phymosis, and never suffered from venereal disease. Subsequently to the blow he could not draw back the foreskin, and the penis became swollen and painful. He has suffered much pain of the part, like the darting of needles, for the last three years. Three weeks before his admission into hospital, a blister appeared on the dorsum of the penis, about an inch behind the orifice of the prepuce; it ulcerated and bled at that point, and there has been a sanious fœtid discharge from beneath the prepuce.

Condition of penis on admission of patient into hospital.—Phymosis, with considerable redness of the entire organ; superficial ulceration at the orifice of the prepuce, and a fungating sore on the dorsum, which bleeds frequently. On grasping the penis it is felt to be of stony hardness to within an inch of the pubes. There are three small glands enlarged in the groin, two at the right side and one at the left. No gland enlarged near the dorsum of the penis.

There was also hydrocele of the right tunica vaginalis, with the testicle at the bottom of the tumour, and *pointing in front.*

Mr. Croly tapped the hydrocele, avoiding the prominen part, which he said was caused by the position of the testicle. Seven ounces and a-half of clear fluid were drawn off.

Mr. Croly held a consultation with his colleagues, when it was decided that amputation of the penis should be performed, which was accordingly done on Saturday, the 6th instant, as follows:—

The patient having been placed fully under the influence of chloroform, the penis was grasped firmly with Ricord's forceps, and held by an assistant. Mr. Croly made a pre-

liminary circular incision through the integuments, behind the disease, and then with one sweep of a stout straight bistoury, severed the organ. Hæmorrhage from the dorsal arteries was arrested by torsion, and the bleeding from the corpora cavernosa by acupressure. A long needle having been passed beneath the corpora cavernosa, and above the urethra, a loop of inelastic iron wire was passed over the needle's point, and fastened by a half-hitch around the eye-end. The urethra was next divided beneath for half an inch, and the mucous membrane stitched to the integuments at each side. A gum-elastic catheter was passed into the bladder and retained by means of a piece of tape, which was fastened to the thighs by strips of adhesive plaster.

The patient was ordered opium in half-grain doses, to be taken every third hour, with one grain of quinine.

The wound was dressed with carbolic acid.

Mr. Croly addressed a few practical remarks to the pupils on this case—first, as regards the importance of accurate diagnosis, and next as to the mode of operating. He directed their attention to the manner in which the skin was first divided by a circular incision, which facilitated the section of the penis, and the necessity for having the end next the pubes held tightly during operation to prevent retraction before securing the blood-vessels. The mode of arresting the hæmorrhage by torsion and acupressure was also fully explained, and the manner in which the urethra was divided and stitched to the integuments to prevent contraction of the orifice.

Mr. Croly also drew the attention of the class to the advantage of passing a catheter fully into the bladder after the operation, which not only keeps open the orifice of the urethra, but also prevents the urine from irritating the raw surface.

Case 2.—FURTHER OPERATION FOR ENORMOUS PROLAPSUS RECTI.

Mr. Croly performed Hey's operation in the case of enormous prolapsus recti (of which we gave a report on the 3rd inst.) in the following manner:—The patient was put under the influence of chloroform, and placed on her left side with the knees flexed. A large fold of integument near the anus was raised with a double tenaculum on each side in the direction of the tuber ischii, and excised with curved scissors, the edges of the wound were then brought together by iron-wire sutures. A third fold of integument was also excised in the direction of the coccyx. The wounds were dressed with carbolic acid ; a compress fixed by strips of adhesive plaster approximating the nates was then adjusted, and a T bandage applied.

Case 3.—LARGE CHRONIC ABSCESS OF THE THIGH FROM MORBUS COXÆ—TREATED BY CHASSAIGNAC'S DRAINAGE TUBE.

A scrofulous boy, aged 10 years, who has had morbus coxæ for many months, was admitted into hospital with a large chronic abscess on the external surface of the left thigh.

Mr. Croly passed a drainage-tube through the abscess in the following manner :—A small incision was made with a lancet through the integuments at the lower margin of the abscess. A long curved trocar was then introduced, and brought out at the upper part. The tubing was next fastened to the hook on the point of the trocar and withdrawn through the canula. The canula was then removed, and the ends of the tubing fastened together.

Mr. Croly observed to the class the advantages of this mode of treating chronic abscesses, of which they have had from time to time several examples. He directed their attention to the precaution necessary to be observed in introducing the trocar to avoid the risk of wounding a vessel in the abscess. This is to be prevented by withdrawing the point of the trocar into the canula when passing it through the abscess.

These cases have progressed most favourably since operation.

RICHMOND SURGICAL HOSPITAL.

Cases under the care of Mr. W. STOKES.

(Reported by Mr. THOMAS ALLMAN.)

STRANGULATED FEMORAL HERNIA OF UNUSUAL FORM AND SIZE : OPERATION WITHOUT OPENING THE HERNIAL SAC : RECOVERY.

To those interested in determining the vexed question as to the propriety or impropriety of opening the hernial sac in operations for strangulated hernia, the following case will probably be of considerable interest.

Mary Dunne, æt. 40, was admitted into Mr. Stokes' wards in the Richmond Hospital, on the 22nd ult., suffering from strangulated femoral hernia. The patient stated that she first observed a tumour about the size of a marble in the right groin about ten years ago. Two years from the present date it increased suddenly very much in size, which the patient attributes to a kick which she got a little below the umbilicus. She never experienced any difficulty in reducing the tumour until the day she sought for admission to the hospital. She stated that while running after a coal-cart (a little before one P.M., on the 22nd ult.), she felt a sudden pain in the groin in the right side, the situation of the hernia, and on trying to reduce the latter was unable to succeed. Shortly after two P.M. the patient was brought into hospital suffering great pain, and vomiting frequently. A full opiate and a warm hip-bath were first given, and the taxis having then been tried, and without success, Mr. Stokes was sent for.

On examination, a very large hernial tumour was found in the right groin, oval in shape, and somewhat constricted in the centre, giving it an hour-glass appearance, and extending from about an inch and a quarter internal to the anterior superior spine of the ilium down into the labium. From the large size, the peculiar form, and the extension of the tumour down into the labium it appeared at first sight to be an inguinal hernia. On careful examination, however, the conclusion arrived at was, that it was a femoral hernia of most unusual form and dimensions. This opinion was found at the operation to be strictly correct.

Shortly after Mr. Stokes' arrival, about six P.M., the taxis was again tried, this time the patient having been brought fully under the influence of chloroform. The attempt, however, was unsuccessful. Directions were then given to administer a second opiate, a tobacco enema, and to keep the patient in a full hot bath for twenty minutes, and after this to try the taxis again. After these directions were carried out, the tumour was found quite as tense as at first, and at 9.30 P.M., the pain in the tumour and abdomen getting worse, and the vomiting continuing, operation was decided upon. The hernia had at this time been strangulated nine hours and a-half. The operation was then performed in the ordinary manner, and the stricture having been divided, the hernia was returned without any difficulty, care having been taken not to open the peritoneal sac.

Shortly after the operation the patient got a full opiate, after which she slept well.

May 23rd.—Suffering much pain in lower part of abdomen, also frequent tendency to retching.

These symptoms were effectually arrested by a mixture contaning sol. muriate of morphia, hydrocyanic acid, and spirit of nutmeg, in cinnamon water.

24th.—Wound looking healthy ; dressed with carbolic acid lotion ; bowels not yet moved ; ordered a full enema.

26th.—Patient had two motions from the bowels to-day ; is free from all pain and uneasiness. Appetite good. Wound healing rapidly.

June 4th.—Wound is perfectly healed ; bowels regular. Patient to return home the following day.

In some clinical remarks on this case, Mr. Stokes observed that the question of opening or not opening the sac in operations for strangulated hernia, is one of the greatest importance, and one about which there is the

greatest difference of opinion among practical surgeons. Hitherto the practice in the Richmond Hospital has been to open the sac in all cases, and the results have, doubtless, been excellent. Recent statistics, however, appear to show the desirability of performing the operation for strangulated hernia, without doing so. From the observation of a considerable number of cases in the Meath Hospital in which the sac was not opened, Mr. Stokes had also come to the conclusion, that at all events when the strangulation was recent, the safest practice was not to open the sac. This was also the opinion of the late Professor Schuh, of Vienna, who published a memoir on "Hernia," of the utmost surgical value.

When the strangulation is recent there can be little danger of ulceration from pressure, producing perforation of the intestine, or of gangrene of the intestine; and if, after the stricture is divided, the surgeon on returning the hernial tumour into the abdomen, *experiences the peculiar gurgling sensation usually felt in the reduction of herniæ, he may be quite sure that no stricture exists within the sack to interfere with the circulation of the part.* In all cases, therefore, of strangulated herniæ, for which operation is demanded, the rule, in Mr. Stokes' opinion, to follow should be, not to open the sac if the strangulation be recent, but if it be not recent, to open the sac and examine carefully the condition of the intestine before returning it into the abdomen.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief Notes by Dr. TONGE.)

(Continued from page 501.)

ACUTE RHEUMATISM.—Emma M., æt. 28, St. J. H., probationer. Admitted April 11; discharged June 3. In hospital 53 days. *Recovery.* Second attack; first 14 years ago. Previously ill, 4 days. Right ankle and knee and left ankle and knee affected successively. All these joints very painful and swollen on admission. Breadth of cardiac dulness increased. Systolic friction sound over heart; sometimes to and fro. Pulse 100. Respiration 36. Slight sweating. Hips afterwards painful. Free from pain on 20th day.

Bicarbonate of potass and decoction of bark, and quinine and opium. After 20th day dilute muriatic acid and bark, and bicarbonate of potass powders. Brandy 4 oz. E. L. to left knee.

ACUTE RHEUMATISM.—J. B., æt. 16, printer. Admitted April 22; discharged May 28. In hospital 36 days. *Recovery.* First attack. Previously ill, 3 weeks. Left elbow, right shoulder, hips, right knee, right ankle, left knee, and left ankle successively attacked. On admission, knees, ankles, and left elbow painful. Profuse sweating. Tongue furred. Pulse 80. On 49th day systolic bruit at base of heart. Free from pain about 56th day.

Bicarbonate and nitrate of potass and decoction of bark (20 days). Decoction of bark (5 days). Then iodide of potassium and bicarbonate of potass. Aperients.

ACUTE RHEUMATISM.—Mary A. G., æt. 31, married. Admitted July 2; discharged July 30. In hospital 28 days *Recovery.* First attack. Winter cough 5 years. Previously ill, 3 weeks. Knees, ankles, shoulders, elbows, and wrists successively affected. On admission, free sweating. Right shoulder and wrist, ankles and feet painful and tender. Tongue white. Physical signs of emphysema. Free from pain on 44th day. Heart unaffected.

Bicarbonate of potass for two days before admission; same, with Dover's powder. Afterwards bicarbonate of potass, aromatic spts. of ammonia, and liq. cinchonæ. Aperients.

ACUTE RHEUMATISM.—W. F., æt. 32, brass-founder. Admitted November 3; *died* on November 10. In hospital 7 days. Second attack; first 12 years ago. Previously ill, 5 days. Heels, feet, and ankles, knees, hips, shoulders, elbows, and wrists successively affected. On 10th day, profuse sweating. Tongue thickly coated. Pulse 126. Respiration 44. Cardiac dulness slightly increased; loud to-and-fro sound over heart. Bronchial breathing at base of right lung. Sleeps badly, and is somewhat delirious. On 11th day, dulness and bronchial breathing over both posterior bases. Trace of albumen in urine. On 12th day, breath shorter; rub over whole of heart. Died suddenly on 13th day.

Bicarbonate and nitrate of potass and decoction of bark (2 days). Then same, with liq. ammon. acetatis. Brandy 4 oz. Mercurial ointment and opium over heart. Turpentine stupes to chest.

ACUTE RHEUMATISM.—Kate B., æt. 12. Admitted November 2nd; discharged December 17th. In hospital 45 days. *Recovery.* Pain in præcordial region and shortness of breath, 14 days; cough 3 days; systolic bruit at heart's apex; tongue coated. On ninth day after admission pain and swelling of right knee and ankle, left knee and ankle, and joints of arms afterwards affected. Five days later, pulse 126; respiration 44; much præcordial pain. Three days later, friction sound at heart's base (6 days). Six days later, almost free from pain; bruit still distinct; pulse 80.

Decoction of bark (10 days). Then bicarbonate of potass and aromatic spts. of ammonia; opiates at night; quinine and opium. After 28th day in hospital aromatic spts. of ammonia, and decoction of bark; brandy 6 oz.

ACUTE RHEUMATISM.—J. C., æt. 33, blacksmith. Admitted August 15. *Died* August 26. In hospital 11 days. Fifth attack; first 12 years ago. Previously ill 3, days. Back, hips, knees, ankles, right hand, left hand, left shoulder, and back of neck affected in turn. On admission pain as above, except in back and left hand; profuse sweating; jaundice; tongue white; breath short, 44; pulse 108; bases of lungs dull; sibilus all over chest; area of cardiac dulness increased; sounds distant; faint systolic murmur at apex. On 5th day great distress of breathing; loud pericardial rub; delirium; no jaundice. *Post-mortem*—Left lung carnefied at base; right lung hepatised; large deposit of recent lymph on heart; valves healthy.

Aromatic spts. of ammonia and bicarbonate of potash; opium; brandy 12 ounces.

ACUTE RHEUMATISM.—Jane A., æt. 14. Admitted October 6; discharged November 5. In hospital 30 days. *Recovery.* Third attack; first 8 years ago; second 2 years ago. Previously ill, 8 days. Right ankle, left ankle, knees, hips, shoulders, elbows and wrists affected successively. On admission shoulders, elbows, and wrists painful; systolic bruit at heart's apex; pulse 116; respiration 36; free sweating; tongue furred. Free from pain on 22nd day.

Bicarbonate of potass, aromatic spts. of ammonia, and chloric ether (5 days). Same with liquor cinchonæ (18 days). Then dilute hydrochloric acid, chloric ether, and liq. cinchonæ. Dover's powder; aperients.

ACUTE RHEUMATISM.—W. A., æt. 22, grocer. Admitted December 17; discharged December 31. In hospital 14 days. *Recovery.* Second attack; first 9 years ago. Previously ill, 4 days. Pain in præcordia, right shoulder, left shoulder, right knee, left knee, right ankle, left ankle, and right wrist and hand successively. On 7th day ankle, knees, right shoulder, hand, and wrist painful; moderate sweating; tongue white; pulse 92; heart sounds distant; convalescent on 14th day.

Bicarbonate of potass, carbonate of ammonia, and chloric ether (6 days). Same with liq. cinchonæ (6 days). Same without pot. bicarb. (2 days). Opiates; aperients.

ACUTE RHEUMATISM.—G. G., æt. 30, coachman. Admitted March 9, discharged May 7; in hospital 59 days. *Recovery.* First attack. Three weeks ago pain in right heel and instep (4 days). Previously ill, 4 days. Right foot, left arm and leg, back, right temporo-maxillary joint, left ankle, ball of left great toe and hips affected successively. Profuse sweating. Tongue furred. Much pain in chest on 11th day. Free from pain on 16th day. On 26th day fresh pain in right shoulder, elbows, and præcordia. Pulse 100. Rub over heart on 31st day, and soft systolic

bruit at heart's base on 41st day. Finally free from pain on 56th day.

Bark and bicarbonate of potass (20 days); iron and calumba (1 day); bicarbonate and nitrate of potass and bark; afterwards iron.

SUBACUTE RHEUMATISM.—A. P., æt. 18, compositor. Admitted August 18; discharged August 30. In hospital 12 days. *Recovery.* Second attack. Pain in chest 1 month. Previously ill 14 days. Left ankle and knee tender and painful. Free sweating; loud systolic bruit at heart's apex (old).

Bicarbonate of potass and aromatic spts. of ammonia.

SUBACUTE RHEUMATISM.—J. A. S., æt. 21, gilder. Admitted March 5; discharged March 11. In hospital 6 days. *Recovery.* Previously ill, 2 days. Pain, redness, swelling, and tenderness of ankles; loss of appetite; tongue furred; free sweating. Free from pain on 5th day. Heart unaffected.

Bicarbonate of potass and decoction of bark (3 days). Then same with sulphate of iron.

CHRONIC RHEUMATISM.—G. P., æt. 32, clerk. Admitted July 30; discharged August 13. In hospital 14 days. *Recovery.* In King's College Hospital for chronic rheumatism last year. Previously ill, 3 days. Pain in left hip, right hip, and left ankle and foot successively; no redness or swelling; appetite bad; tongue clean. Pulse 68.

Iodide of potassium, bicarbonate of potass, and liquor cinchonæ.

CHRONIC RHEUMATISM.—Mary W., æt. 76. Admitted February 22; discharged March 26. In hospital 33 days. *Relieved.* Rheumatic pains in wrists and finger-joints, 1 year. Senile debility.

Aromatic spts. of ammonia, chloric ether, liquor cinchonæ, and bicarbonate of potass. J. P. to fingers.

RHEUMATIC INFLAMMATION OF ELBOW.—Maria D., æt. 22, servant. Admitted March 31; discharged April 25. In hospital 25 days. *Relieved.* Previously ill 14 days. Right foot, left knee, right hand, and left elbow affected successively. On admission, left elbow red, swelled, tense, and painful; œdema extending up and down arm; tongue furred. No other joint affected. Alkalies.

MUSCULAR SPASM.—Elizabeth W., æt. 13. Admitted March 29; discharged April 9. In hospital 11 days. *Recovery.* Previously ill, 1 day. Feet turned in; hands contracted; thumbs drawn into palms; slight pain in muscles of calves. Well 2 days later. Had a similar attack 3 months ago, well in 4 days. Castor oil, tinct. opii., mxx. h.s.s.

WEDNESDAY, JUNE 17, 1868.

SPECIALISM.

THOSE who pursue our noble calling with a single eye, cannot escape from a feeling of poignant regret at the divisions which continually arise and give occasion to the criticisms of the public. We admit freely that to be a doctor in the good old sense, is a far superior thing than to be a pure specialist as this word is too commonly understood. But extremes meet. It has become the rage to pander to the ignorance or the prejudice of the public or of a section of the profession, and there lives and thrives amongst us a class of men that deserves but scanty respect.

Looking at this class with a feeling of indignation, and ever ready to attack it, some have been so far led away as to confuse with it a far superior class, and to utter denunciations that savour of personal irritation or of thoughtless arrogance. Few things can be more absurd in the present day than to maintain that any one intellect is capable of grasping the whole range of all the sciences, and of applying all their principles to every individual case of disease. Yet this is what the campaign against specialism, so persistently waged by some of our contemporaries, is leading to. They would seem to assert that there can be no case calling for special knowledge, that he who devotes his life to the elucidation of one set of phenomena cannot be more informed respecting such phenomena than he who, with a large ambition, attempts to grasp the whole of nature's laws.

We demur to such a proposition. Still more do we grieve that it should be maintained by the most unworthy, if not the most worthless, arguments and assertions that have ever disgraced the annals of our art. We are, perhaps, unfortunately deeply imbued with the honour of our profession, and when its principles or its practice are dragged in the mire to serve the purpose of the purveyors of claptrap, we cannot but feel that there is great danger lest the assertions of dogmatic sensationalists should be received as the echoes of professional opinion. For this reason we are constrained once more to take up the gauntlet on behalf of the much maligned specialists, who are so obnoxious to some of our contemporaries. In doing so, we can scarcely repress our impatience at the marvellous impudence with which the war against specialism has been carried on. No insinuation has been too repulsive, no accusation too dark, to be hurled at the heads—not of one or two who richly deserve all that can be said,—but of hard-working, honourable men who, because forsooth, they have most studied one branch of the art of healing are to be held up to scorn as mere specialists—whatever that term is meant to imply, and who are to be placed, if possible, outside the professional pale.

As well may the accomplished accoucheur be ignored as an ignorant midwife, the skilful surgeon as a mere butcher.

Operative surgery is, as all admit, a great art in which some few peculiarly excel, and others, having large opportunities, are greatly experienced. The same may be said of many other branches of the profession.

Division of labour has been recognised by the public as essential to excellence, and the profession itself has endorsed the verdict. We have come to see that it may lead to advancement in science and practice, and the fierce denunciation of its extremes will only produce a stronger reaction in its favour. Let us then meet the facts honestly and openly, and not be carried away by selfishness or thoughtlessness.

Let us not be misunderstood. Personally, we have no sympathy with excessive subdivisions of the field of study. We have no desire to see arise amongst us, a generation of men restricting their ideas to a narrow sphere, and letting their minds be "cribbed, cabined, and confined," by contracting them within the smallest possible compass.

We know well enough the tendency that exists in human

nature to keep its best efforts for the field which possesses most interest, and, therefore, we have no desire to see *all* our noblest minds rigidly confining their ideas to any branch of science or practice. Nevertheless, since no single intellect may grasp all knowledge, we are content that most should forego much for the sake of attaining excellence in some one or more departments. Is it not thus that the profession as a whole acts? Do we ask that a great physician should be a great astronomer, or geologist, or mathematician, or linguist, or logician, or even physicist? We have admitted practically that he need not be a great chemist, or even physiologist.

We look outside the range of the physician for progress in these sciences, and surely they much concern him. He is but too glad to avail himself of the labours of those who devote themselves to them. Still more, we have in our great towns separated medicine, surgery, and midwifery almost as completely as possible. Why, then, should some further subdivision shock all the proprieties and enrage the advocates of things as they were? Honestly followed, any branch of our profession affords ample scope for study, and if, as we admit, our art as a whole is a still nobler study, and tends still more to enlarge our minds; as a noble whole cannot be made up of ignoble parts, so we are reluctant to admit that the specialist is to be despised; and we offer our solemn protest against the flippant slander that has lately been too constantly levelled against men whose only crime seems to have been that they successfully cultivated one branch of an art, while others—more ambitious, and therefore desirous of excelling in all—as signally failed.

THE VOTING CLAUSES IN THE SCOTCH REFORM BILL.

When our number last week came into the hands of its readers, the article on this subject might seem a day too late, as the debate had then been closed and the vote taken. We are glad that the most unjust part of the proposal was rejected without much delay, though we have reason still to confess to dissatisfaction.

We think it right to recur to the subject, since it is only just to report that Mr. John Stuart Mill led the opposition to the clause against which we most protested. He pointed out most forcibly the manner in which half, or more than half, the University constituency might thus be disfranchised, and to him, therefore, belongs the credit of the victory gained on that occasion.

At the same time, that debate illustrates most forcibly the inability of Mr. Lowe to appreciate a truly liberal view or to sympathize with university constituencies. It is strange that a gentleman of his undoubted ability, and one who aspires to represent the University of London, should have twice returned to the assault against Mr. Mill's amendment, and urged all sorts of idle pleas for obstruction. Nothing could so fully demonstrate Mr. Lowe's utter unfitness for the post he seeks. Let the plan he sought to inculcate be enforced, and the consequence would be to create such a constituency as would, within a few weeks, lead to a cry for a reform of it being urged. If a man is to possess a vote at all, nothing can be more inconsistent than to fence it round with a series of restrictions that deprive it of all its value. Giving with one hand and taking away with another, is a process that the graduates of the London University would do well to remember when Mr. Lowe seeks their support, that he strongly justified in the case of the Scottish Universities We have before had occasion to point out emphatically the disqualifications of Mr. Lowe to represent any university, but this last escapade evinces a greater perversity, or a great obliquity of vision, than we had hitherto given him credit for. It ought to determine London University men on finding one of their own graduates (a medical one would be best), or at least a representative of the scientific world, instead of accepting a political notoriety.

THE CARMICHAEL PRIZES.

The *Medical Times and Gazette* is responsible for the publication, in its last issue, of a letter which, while giving expression to very serious charges against the Council of the Royal College of Surgeons in Ireland, in respect of the recent award of the Carmichael prizes, makes statements which are not only utterly devoid of truth, but which display complete ignorance on the essential points of the indictment. On this letter and on apparently insufficient inquiry or consideration, our contemporary basis a leading article, in which it authoritatively adopts not only the tone but the facts of its correspondent's communication. The writer firstly objects to the adjudication on the ground that Dr. Mapother, one of the successful competitors, is a Member of the Council who, as the writer says, are the adjudicators. The real truth is that the Council at large, although nominally the arbitrators, appointed three of their number to be judges, with instructions to examine and to decide upon the merits of the various essays. A fictitious signature was appended to each essay, and while no Member of Council except this committee of three ever saw these treatises not even the judges themselves could have had the least idea of the authorship of each. It happens that Dr. Mapother's essay (being intended by its author for subsequent publication, whether it might be selected for the prize or not) was presented to the judges in the form of a printed slip, so that, in fact, they had not even the hand-writing of its author to suggest to them his identity, nor were the Council aware that Dr. Mapother intended to compete, or had competed, until the envelope containing his name was opened at the public meeting, after the award had been decided. Thus the insinuation of corruption in the Council, so readily adopted by the *Medical Times and Gazette*, turns out to be impossible and untrue.

There was no restriction whatever in Mr. Carmichael's will excluding Members of Council from the competition for the simple reason that, under the bequest, the arrangement for the award made it impossible that the arbitrators should know beforehand who were the competitors. In point of fact, Dr. Mapother competed for the prize, and, as he justly merited, obtained it, in his private capacity, nor did his position as councillor in any respect militate in his favour, the fact of his being a competitor being studiously concealed.

The correspondent of the *Medical Times and Gazette* proceeds to say that the Council of the Royal College of Surgeons having advertised a first prize of £200, and a second of £100, awarded £400 and £200 instead to each prize respectively. This statement is untrue in substance and in fact, and the *Medical Times and Gazette* recognises it as incorrect, and yet permits it to go forth through its columns.

The Council has power, under Mr. Carmichael's will, to double the amount if (in consequence of the award not hav-

ing been made for any one year) the interest on the original bequest should be doubled. That power is confided to the Council according to the terms of Mr. Carmichael's will, "at its discretion," but it has not as yet availed itself of the privilege, nor is its course of action in the matter yet determined.

The Council has, while desiring to discharge the trust confided to it in awarding the prize to the best essay, endeavoured most carefully to avoid the suspicion of bias, and it is, therefore, greatly to be regretted that a journal enjoying the character for moderation and equity which the *Medical Times and Gazette* has possessed, should not only give publicity to incorrect and prejudiced statements, but should, without sufficient consideration, adopt them as facts.

NOTES ON THE ABYSSINIANS.

NOTWITHSTANDING the prominence recently given to everything Abyssinian by the successful expedition of Sir Robert Napier, and the tragical death of King Theodore, little has been set before the public regarding the domestic life and personal habits of this ancient and interesting nation. Perhaps the best information on these subjects may be had from a book, published in London in 1853 by Mr. Mansfield Parkyns, and entitled "Life in Abyssinia, being notes collected during three years' residence and travels in that country."

The second volume of this work is largely devoted to the inner life of the Abyssinians, and chapter xxviii., on their personal appearance, dress, &c., furnishes the medical reader with much that is interesting, and not generally known.

Their mode of dealing with the hair is thus described, the "quarry" mentioned by Mr. Parkyns being a modification of the ancient Roman *toga*, which is a national costume in Abyssinia :—

"In general, neither sex wears any covering on the head preferring to tress and butter that with which nature has provided them. The hair of the Abyssinians is admirably adapted for this purpose, being neither short and crisp like a negro's, nor yet of the soft elasticity of a European's, but between the two; sufficiently long to tress well, and even often to hang luxuriantly over the shoulders, but at the same time sufficiently woolly to prevent its being liable to come out of plait as soon as it is done, which ours always does. I had the greatest bother in the world with mine. In the first place, it required twice as much pulling as anybody else's, otherwise it would not have remained a moment in its place; and then it had to be tied at the ends and stuck with a 'fixature' of boiled cotton-seeds; and after all, it never lasted in plait more than a week.

"The operation of tressing is a very tedious one, usually occupying an hour or two per head; therefore, of course, it is repeated as seldom as possible: by some great dandies once a fortnight; by others once a month, or even less frequently. In the interim large supplies of fresh butter are employed, when obtainable, in order to prevent the chance of a settlement of vermin; and a piece of stick, like a skewer, is used for scratching. The hair is gathered in plaits close over the whole surface of the head, the lines running fore and aft, and the ends hanging down in ringlets over the neck. In both sexes the patterns chosen are various. Some will have only five or seven plaits, while others will prefer as many as thirty or more. Some again have the whole of the head tressed backwards; others wear the front part plaited towards the sides, with the ends hanging over the temples. Formerly young soldiers were not allowed to tress their hair until they had killed a man, when they shaved the whole of the head, leaving only a single plait; another was added for each man killed, till they had reached the fifth, when they were privileged to wear a whole head of hair. Now-a-days, excepting in some of the remote Galla districts, the number of tresses depends on the age of the wearer rather than on his prowess. Youths and young women usually shave the crown, like a priest; while mothers and full grown men tress the whole. Some ladies have their butter daubed on nicely, and then some scent; but the great 'go' among the dandies is to appear in the morning with a huge pat of butter (about two ounces) placed on the top of the head, which, as it gradually melts in the sun, runs over the hair down the neck, over the forehead, and often into the eyes, thereby causing much smarting. This last ingression, however, the gentleman usually prevents by wiping his forehead frequently with his hand or the corner of his 'quarry.'

"As may be imagined, the dresses neither of the women nor men are long free from grease; but this, especially among the latter sex, is of no importance: indeed, many young men among the soldiery consider a clean cloth as 'slow,' and appropriate only for a townsman or a woman. These never have their quarries washed from one St. John's day to another: even the young Prince Shétou is more often seen in a black quarry than a white one."

The process of tattooing appears to be not uncommon among them, and gives rise to a profession in itself, devoted to the daily pursuit of this practice. The Abyssinian practice, in this respect, seems to resemble that of the South Sea Islanders, and is thus described :—

"The Tigrèan ladies, and some men, tattoo themselves, though, as this mode of adorning the person is not common excepting among the inhabitants of the capital and persons who have passed some time there, I should judge it to be a fashion imported from the Amhára. The men seldom tattoo more than one ornament on the upper part of the arm, near the shoulder, while the women cover nearly the whole of their bodies with stars, lines, and crosses, often rather tastefully arranged. I may well say nearly the whole of their persons, for they mark the neck, shoulders, breasts, and arms, down to the fingers, which are enriched with lines to imitate rings, nearly to the nails. The feet, ankles, and calves of the legs, are similarly adorned, and even the gums are by some pricked entirely blue, while others have them striped alternately blue and the natural pink. To see some of their designs, one would give them credit for some skill in the handling their pencil; but, in fact, their system of drawing the pattern is purely mechanical. I had one arm adorned; a rather blind old woman was the artist; her implements consisted of a little pot of some sort of blacking, made, she told me, of charred herbs; a large home made iron pin, about one-fourth of an inch at the end of which was ground fine; a bit or two of hollow cane, and a piece of straw; the two last-named items were her substitutes for pencils. Her circles were made by dipping the end of a piece of cane of the required size into the blacking, and making its impression on the skin; while an end of the straw, bent to the proper length, and likewise blackened, marked all the lines, squares, diamonds, &c., which were to be of equal length. Her design being thus completed, she worked away on it with her pin, which she dug in as far as the thin part would enter, keeping the supply of blacking sufficient, and going over the same ground repeatedly to ensure regularity and unity in the lines. With some persons, the first effect of this tattooing is to produce a considerable amount of fever, from the irritation caused by the punctures; especially so with the ladies, from the extent of surface thus rendered sore. To allay this irritation they are generally obliged to remain for a few days in a case of vegetable matter, which is plastered all over them in the form of a sort of green poultice. A scab forms over the tattooing, which should not be picked off, but allowed to fall off of itself. When this disappears, the operation is complete, and the marks are indelible; nay, more, the Abyssinians declare that they may be traced on the person's bones even after death has bared them of their fleshy covering."

There are various customs connected with the births, deaths, and marriages, and medical superstitions of this people, which we hope to notice in future numbers of this journal.

Notes on Current Topics.

The Public Health.

As usual, we quote from the weekly return of the Registrar General, which shows that there were registered in London and 13 other large towns of the United Kingdom, 4353 births and 2664 deaths during the week that ended on Saturday, June 6th. The annual rate of mortality

was 22 per thousand persons living; being 19 per thousand in London, Edinburgh, Bristol, and Newcastle-upon-Tyne; 29 in Salford, Bradford, and Glasgow; 25 in Dublin; 17 in Birmingham; 26 in Liverpool; 23 in Manchester; 24 in Hull and Sheffield; and 21 in Leeds.

In London the deaths registered during the week were 1160, being 89 less than the estimated number.

The deaths from zymotic diseases were 293. Sixteen deaths from small-pox, 60 from measles, 41 from scarlatina, 12 from diphtheria, 47 from whooping-cough, 34 from fever, and 27 from diarrhœa were registered.

A leather dresser, aged 50, died of "choleraic diarrhœa, 24 hours;" 3 persons died from intemperance; 2 from delirium tremens; 5 infants and 2 adults from syphilis; 3 children from burns and scalds; 12 persons from drowning; 4 infants and 1 adult from suffocation; 7 persons committed suicide; and 7 were killed by horses or carriages in the streets.

Health of Bombay.

In his report for 1867, Mr. Hewlett, the health officer for this city, states that the deaths registered during that year amounted to 15,500, being 19 to every 1000 of the population. This proportion is considerably less than in either of the three preceding years, and shows that there has been a great improvement in the public health since 1865. The deaths from the principal epidemic diseases in 1867 were:—Cholera 111; measles 24; fever 5674; and small-pox 1055. Of the latter, as many as 836 were children under 9 years of age, which may be accounted for, probably, from the fact that vaccination is not compulsory there. The mortality per cent. of the different castes or races is given, among which that of the Indo-Europeans shows favourably, being less, with two or three exceptions, than any of the others.

London College of Physicians.

Last Wednesday the annual *soirée* of the College was held, when most of the eminent physicians and surgeons of London, and other distinguished persons, were present. Dr. Alderson, the president, Dr. Farre, and Dr. Wegg, introduced the visitors. Many objects of interest were exhibited on the occasion, among which were type-writing and ice-making machines, microscopes, and microscopic specimens of various kinds, a magneto-electrical machine specially arranged for medical purposes, panoramic and stereoscopic slides, photographs, especially views taken in Abyssinia, as well as exhibitions in other departments of science and art, which drew the attention and added to the enjoyment of the company.

The Election of Council of the Royal College of Surgeons of England.

The four vacancies in the Council to which the elections will shortly take place will be contested by no less than nine competitors. Sir W. Fergusson, Mr. Partridge, Mr. Erasmus Wilson, Mr. Charles Brooke, Mr. Gay, Mr. Luther Holden, Professor Humphry, of Cambridge, and Mr. George Cooper. Sir William Fergusson will almost of necessity be one of the four, while Mr. Partridge and Mr. Erasmus Wilson are regarded as probable successors to other seats. The fourth will be anxiously disputed—Professor Humphry for the provincial Fellows, Mr. Holden for St. Bartholomew's, and Mr. Brooke, Mr. Gay, and Mr. Cooper on their own very decided merits.

Small-pox Hospital.

The Medical Officers of this institution have just issued their annual report, from which it appears that the epidemic of small-pox, which has now extended over more than five years, still continues. The admissions to the hospital were fewer last year than in 1866, but still with that exception the number was larger than in any previous year since its foundation. In the five years 1863-7 the yearly average number of admissions was 1463. Last year the number admitted was 1626. During 1867 the proportion of vaccinated cases was 84·1 per cent., and the deaths reached 206, being in the proportion of 12 per cent. of the admissions. In all London the deaths from this disease amounted to 1332 in that year. After deducting all expenses the funds of the hospital show a balance of £918 in its favour.

Metropolitan Asylum Board.

On Saturday, the 6th inst., a meeting of this Board was held to consider the mode of erecting the proposed new hospitals at Hampstead. It was decided that accommodation should be provided for 104 fever patients, and that there should be arrangements for small-pox wards on the adjoining ground, though it was resolved that there was no present need for such an addition to the building. The extent of the wards is to be 2000 cubic feet, and the size of the bed-rooms 180 superficial feet.

Adulterations.

Leave was given to Mr. Dixon on the 9th instant to bring in a bill, which was read the first time in the Commons, to amend the "Act for Preventing the Adulteration of Food and Drink, 1860," and to extend its provisions to drugs. The bill, he said, would increase the penalties, extend the provisions against adulterations to the manufacturers of articles containing adulterations prejudicial to health, make the appointment of analysts obligatory, and provide for the appointment of a public officer to undertake prosecutions against offenders under the Bill.

Monstrous Birth.

The Berlin journals give an account of a remarkable monster of which the wife of a joiner at Schkeudnitz has been delivered on the 26th of May. It was a still-born child, apparently of normal length, but with a somewhat large thorax. Between the shoulders two well-formed and shaped heads are to be seen, covered with hair; the features are well wrought, each head being on a rather long but strong neck, and between the two necks a third arm projects, which is somewhat bigger than the two normal arms; the hand of that arm has two thumbs in an opposite direction, producing the impression of two arms having been united in one. One day before delivery, all the signs of a living fœtus had been observed. The mother had borne several healthy children, and in this instance too the time of pregnancy was perfectly normal.

The Female Obstetricians and Dr. Eastlake.

The cross-actions between Dr. Edmunds and Dr. Eastlake, which have arisen out of the removal of Dr. Eastlake from the office of Physician to the British Lying-in-Hospital, are expected to come before the Courts to-day and, no doubt, the excitement not only of the personal quarrel but on the general question of female medical practice will run high. The facts will be in the remembrance of our

readers. Dr. Eastlake complained to the Governors of the British Lying-in-Hospital that one of the training midwives surreptitiously applied instruments to a patient under his care. The Governors, instead of discharging or seriously censuring the nurse, called for Dr. Eastlake's resignation, and that gentleman avers that the opportunity was seized by a certain party connected with the Female Medical College to expel him, because he had objected to a proposed amalgamation of the College with the Lying-in-Hospital, and Dr. Edmunds constitutes himself the mouthpiece of this party.

It is not for us, in the present state of the controversy, to do more than state facts. We may, however, say that, as far as the profession is as yet informed, Dr. Eastlake's cause is considered to deserve their entire sympathy.

Medical Muscularity.

THE Olympian games of the London Medical Students have been entirely successful this year. For the second anniversary of the United Hospitals' Athletic Club, which was celebrated on Thursday and Friday last, we may say that the prizes were worthy of the object, and the contests worthy of the prizes. This movement, of which we have already expressed our entire approval, appears to receive a very real support from the heads of the profession who do not consider that play is by any means incompatible with industry. Sir Thomas Watson presented a handsome bronze clock as a prize for the quarter mile race, and Dr. Owen Rees a fine silver cup for the 120 yard contest. Amongst the spectators were Sir Thomas Watson, Mr. Solly, Drs. Sieveking, Chambers, Barnes, Durham, Croft, and others, whose presence may be taken as an approval by their seniors of the students' movement. The remaining races of 880, 440, and 50 yards take place at Teddington on Wednesday, July 1st.

O'Sullivan v. the Limerick Guardians.

THE action taken by Dr. O'Sullivan, the ex-Medical Officer of the Limerick Union, against the guardians for wrongful dismissal, is on the cause-list for this term, and will probably give rise to much medico-religious controversy. The matter has been already noticed at length in our columns some months ago. It arose out of a contest for pre-eminence between the Sisters of Mercy, who were placed in charge of the Union Hospital, in the capacity of nurses, and Dr. O'Sullivan. A series of charges and countercharges, and of enquiries thereon, resulted in Dr. O'Sullivan's dismissal, which that gentleman alleges to have been illegal. The point at issue will be whether Dr. O'Sullivan was appointed as *Resident* or *Assistant* Medical Officer—a distinction which carries with it a summary power of dismissal. Dr. O'Sullivan depends on the wording of the advertisement on which his appointment was made, while the guardians declare that he was an assistant, and acted as such. The question is at bottom a religious controversy, with which we have no wish to soil our columns.

THE renowned Professor Traube has not been able from ill health to continue his lectures and practical demonstrations for a long time, during which he tried to restore his health in the sunny clime of Italy. But feeling, after his return, that he was not able to resume his duties, his wards at the Charité and Lectureship have, provisionally, been conferred on Dr. C. Westphal.

ON the 1st inst., Dr. Volkman, of Elbeig, Western District of Prussia, fell a victim to typhoid fever. He was Physician to the Fever Hospital erected during the prevalent epidemic, and had 200 patients under his care, of whom a very large majority had recovered.

SOME rumours having been current at Berlin, that cases of cholera have occurred in that city, the official press contradicts the truth of the rumour, but advises at all events to begin disinfection of closets as much as possible, the prevailing heat being favourable to the productio n of cholera.

Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By C. R. C. TICHBORNE, F.C.S.L., Etc.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

CRYOLITE.

MR. SAMUEL SIMES, in an Inaugural Essay published in the *American Journal of Pharmacy*, gives a history of this important mineral. It has been used commercially with such success, that it will require no apology to give a slight sketch taken from the above essay.

Small and scattered fragments of this mineral had been found from time to time at Miask, in the Ural mountains, but it was until lately looked upon as rare. Its occurrence in Greenland, the country from which it is obtained in immense quantities, is also limited as to situation, being lat. 61°, in long. 48° W. The main deposit of it here forms a mass about 6000 feet in length, and 200 feet in breadth, and of unknown depth.

Cryolite is a fluoride of sodium and aluminium.

$$3\,Na\,Fl + Al_2\,Fl_3$$

3 Na	= 69
2 Al	= 27·5
6 Fl	= 114
	210·5

As it is found it is in the form of a crystalline mass, having a special gravity 2·95, hardness 2·05. Large portions of it are often found perfectly colourless, and pure and unmixed with foreign matter, while other portions of it contain crystals of spathic iron ore and an ore of iron having a foliated structure—galena, copper and iron pyrites.

The main value of cryolite as a source of soda, alumina, and aluminium, is dependent upon the extraordinary purity that attends its proportions when used on the large scale in their industrial enterprises. The carbonates and hydrate of soda, when obtained by the ordinary processes, viz.—from the decomposition of salt, are always contaminated with more or less of the foreign salts remaining undecomposed from the processes through which they pass. With the cryolite the decomposition is so simple, the manipulations so few, and the ingredients which are used so pure in themselves, that no difficulty exists in obtaining these chemicals in quantities of hundred of pounds, and in a state of almost absolute purity—a purity that was before considered of impossible attainment in quantities greater than these which could be obtained in an analytical laboratory.

The cryolite is ground with six equivalents of carbonate of lime or slaked lime. This mixture is then exposed to a low red heat, with certain precautions, for two hours. The ash thus produced is allowed to cool, when it is placed in an iron tank and treated with hot water, until all the soluble matter is removed. The insoluble residue consists of fluoride of calcium, which, when dry, is an article of great value to metallurgists in reducing gold and silver ores, and as a flux for silicates. The solution consists of equal parts of aluminate of soda, and either carbonate or hydrate of soda, as one of the other forms of lime have been used. In order to separate the alumina and convert the soda into carbonate, a continuous stream of carbonic acid is passed through. In a few hours the absorption of carbonic acid is complete, and the alumina separates in the form of a fine granular powder, which is terhydrate of alumina. The liquor is evaporated to produce washing-soda, and the alumina is dissolved in boiling diluted sulphuric acid,

to form the tersulphate of alumina ($Al_2O_3 + 3SO_3$) having an excess of alumina always present. Sulphate of alumina as thus prepared is a white translucent substance, having the hardness and appearance of alabaster. On account of its basic properties, its small amount of iron, and its trifling cost, it is largely used by calico-printers, sugar-refiners, paper-makers, &c., who consume it in immense quantities.

Cryolite is also used for making aluminium.

The amount of cryolite imported into the United States in 1867, was 8000½ tons, a large quantity of which was used in the manufacture of "opaque white glass." The new porcelain as it has been called, resembles the finest French porcelain in appearance, and is used in making statuary, evaporating dishes, funnels, &c.

The cryolite mines belong to a Copenhagen Company. This company, during the summer of 1867, sent out 19 vessels having an average capacity of 450 tons. Two were lost on the ice. The approach to the coast is always considered dangerous on account of the immense fields of ice, which in hot weather are most likely to be met with descending from the northern latitudes. These form an impenetrable belt of upwards of 80 to 100 miles in width. If this icy belt was a continuous one during the open season, navigation would be as impossible in the northern latitudes as it is on the eastern coast, but off the western coast of Greenland the wind from the north scatters the ice, so that a good navigator availing himself of the opening, can sail in or out without delay. No loss of life has occurred as yet in this trade, as the ice affords a safe refuge for the crew until they are removed by the Esquimaux, or escape by their boats to the settlement. The mines are worked only during the summer season, from May to October, during which time 150 men are employed, and 6000 tons are employed in the manufacture of soda alone, which gives employment to over 500 hands.

CONVERSION OF CARBONATE OF AMMONIA INTO UREA.

Among the many curious reactions that have been lately noticed, none are more interesting than one mentioned by Professor Kolbe. M. Alex. Basaroff heats carbamate of ammonia in strong hermetically closed glass tubes to 130°—140°C. for a few hours. If the contents of the tube be afterwards heated in a water-bath the excess of carbonate of ammonia volatilizes, and pure urea remains. The author has since found that ordinary carbonate of ammonia when treated in the manner just described likewise yields urea. It is probable, however, that this carbonate of ammonia contains carbamate. This is the third process by which this interesting organic product can be made artificially.

POISONING BY MATCHES.

The Paris correspondent of the *Chemical News* (May 29th) cites a case of medico-legal chemistry which was tried at Marseilles. Lucifer matches, it was said, had been used in poisoning the victim. The chemist stated that he had failed to detect phosphorus (the body had been interred two years), as it was probably volatilized or oxidized long ago, but he concluded that matches must be present, because he found pieces of melted sulphur, which he exhibited. The question was then put, did he know that sulphur similar to that which he had exhibited was found in deposits of fecal matter which had undergone a certain fermentation in the air, and upon this point the finding of sulphur perfectly crystallized, and in concrete masses in the old deposits in the sewer of Montfaucon was cited; the specimens of sulphur here referred to are preserved in one of the public museums. Judging from the chemist's evidence, says the correspondent, he would appear to have argued farther than the experimental data justified him in doing. The prisoner was acquitted. Now, without entering into the merits of the case just tried, or the finding of sulphur in the sewers of Montfaucon, we are of opinion that it would be very difficult to induce any chemist to come to the conclusion that solid sulphur in lumps was deposited from the decomposition of human bodies, even in the space of two years, or to come to any other conclusion than that the sulphur, if found in the body, must have been taken in mechanically, as sulphur.

HYDRARGYRI IODIDUM VIRIDE B.P.

Mr. C. Wood has been investigating this compound, and finds that the green powder consists of—

Mercuric iodide HgI_2	28·6
Mercurious iodide HgI	58·4
Metallic Mercury	13·0
	100·

By constant trituration, the last portions of the metallic mercury reaches a fine state of division, and in this form the mercury possesses the blue colour so well-known in blue pill, which, mixed with the yellow of the mercurious iodide already formed, produces the greenish powder. But the true colour of the mercurious iodide is yellow, and to obtain pure mercurious iodide by the process given in the Pharmacopœia, the trituration should be continued until the green mass which forms becomes dry, and assumes a dull yellow colour.

SOLUBILITY OF XANTHINE (URIC OXIDE) IN DILUTED HYDROCHLORIC ACID.

In most of the works xanthine is said to be not soluble in hydrochloric or oxalic acid, and that it may be distinguished from cystine by this reaction, whilst Dr. Marcet (its discoverer), and Schlossberger, say that it dissolves freely in hydrochloric acid, and on cooling the combination is deposited in a crystalline form.

A portion of a calculus of this substance was examined by Dr. Bence Jones, with a view to determine this point.

It was distinctly soluble in diluted hydrochloric acid, even in the cold. It dissolved much more rapidly when heated, and on evaporating the solution to dryness, it gave most characteristic microscopic six-sided crystals, soluble in water. The author failed to reproduce artificially the crystals of xanthine; by dissolving it in urine slightly alkaline, no crystalline deposit formed on standing, or on evaporation. It is probable that these crystals are more likely to be found in the urine of children.

EGG-ALBUMEN.

Mr. J. Spiller, in remarking upon the fact that white of egg is used in the moist state as the standard of comparison in estimating the quality of potable waters, gives some statistics which are interesting from a physiological point of view.

A new-laid egg exhibits no cavity on breaking the shell, whilst a stale one always contains a considerable air-space from the evaporation of the water of the albumen through the shell; so that the white of egg contains variable proportions of albumen, according to the age of the egg.

The weight of a hen's egg was taken, and then supported upon a wire tripod-stand, so that the air might have free access. It lost exactly one grain in twenty-four hours, and this ratio of loss, by evaporation, remained tolerably constant during several days. It was noticed as an anomaly that a heavier shell permitted a faster rate of evaporation through its substance than the one first experimented with. The latter appeared, however, on inspection, to have a smoother external surface, and to be stronger and more compact in structure throughout.

It would be difficult to prove whether or not the water lost by evaporation from the white is partly compensated by an accession of water by diffusion from the yolk. No colouring matter travels outwards, says Mr. Spiller, unless an organic decomposition sets in, when all the natural barriers are destroyed, and the several parts of the egg become merged.

He is inclined to think that the redistribution of water actually occurs, since the sac of the yolk appears wrinkled in a stale egg, as though by loss of a portion of its liquid contents.

The composition of fresh egg albumen may be said to vary between the following limits:—

Water	88 to 85 per cent.
Dry albumen (containing nitrogen 1·55 to 1·75 per cent.) ...	12 to 15 per cent.

CHARACTERISTICS OF THE DIFFERENT VARIETIES OF CREOSOTE.

Beechwood creosote gelatinizes with its volume of collodion. Creosote from coal (carbolic acid) does not.

Wood creosote is insoluble in ammonia, and gives, with excess of potash, a turbid solution.

Carbolic acid from coal is insoluble in cold ammonia, but dissolves on the application of heat. It also gives a clear solution with weak liq. potassæ.

With a neutral solution of perchloride of iron, wood creosote dissolved in alcohol gives a green colouration, the coal-tar product, brown.

With aqueous solutions, on the contrary, coal creosote furnishes a blue.

IODHYDRIC ACID.

C. Winkler prepares this acid by passing a current of sulphuretted hydrogen through water containing iodine in suspension. The iodine is dissolved in bisulphide of carbon. Water is placed upon the top of this solution, and the sulphuretted hydrogen is passed through the bisulphide of carbon.

The hydriodic acid is dissolved in the water, whilst the sulphur remains dissolved in the bisulphide of carbon.

PRESENCE OF SULPHATE OF LIME IN FILTERING PAPER.

M. Krüger *(Jour. de Phar. et de Chim.)* draws attention to the large amount of sulphate of lime in filtering paper, which is due to chloride of lime used in bleaching the pulp. He does not think that the admixture is intentional, but is probably due to the action of the antichlor (hyposulphite of soda) upon the lime salts. He remarks that more attention should be paid to the washing of the pulp.

CARBONYLIC SULPHIDE.

An account of this body, taken from the *Ann. Ch. et Pharm.*, appears in the *Chemical News* of June 5th. This body is intermediate between carbonic anhydride and bisulphide of carbon. Its existence has been long foreseen. M. Thain has recently succeeded in forming it and in determining its properties. Into a cooled mixture of five volumes of concentrated sulphuric acid and four volumes of water, is placed as much sulphocyanate of potassium as will allow the mass to remain fluid. The evolution of gas commences spontaneously. Should it become too violent the flask is placed in cold water. The gas is passed over cotton covered with moist oxide of mercury, then pieces of caoutchouc to remove bisulphide of carbon, and, finally, chloride of calcium to dry it. The gas is collect over mercury.

Carbonylic sulphide (COS) is a colourless gas, with an odour not dissimilar to carbonic acid, but at the same time aromatic, recalling sulphuretted hydrogen, though not at all disagreeable. It is soluble in its own volume of water, to which it communicates its odour. After a few hours this solution, however, exhales a strong odour of sulphuretted hydrogen. It is twice as heavy as air, and may be poured from one vessel to the other. It reddens litnus much more than carbonic acid. It burns with a beautiful blue flame, taking fire very readily. In the opinion of the author this gas is widely distributed in nature, and has not been discovered because it is so easily decomposed by water into CO_2 & HS. From some experiments of his own, Thain asserts that this compound occurs in many remarkable thermal springs in Hungary.

Literature.

DYSPEPSIA.

Dr. Wilson Fox's book on Dyspepsia[1] embodies the results of many years diligent enquiry into the pathological origin, the diagnosis and the treatment, of this complaint; and after carefully reading the work, we have no hesitation in strongly recommending it as a most useful hand-book and guide to the practical physician in dealing with the various derangements of the human stomach.

The two plates, at the commencement of the book, are most perfectly executed in every respect, and exhibit the effects of chronic and acute gastric catarrh in inducing degeneration of the stomach tubes and glands.

In plate 2 are diagrams showing infiltration of the tissue with lymphatic elements in a case of catarrh of the stomach, associated with heart disease, and also two most interesting figures (Nos. 18, 19) shewing ulceration of the stomach in tuberculosis and typhoid fever. After an introductory chapter on the nosological classification of dyspepsia, we come to a short and highly practical one, on the general symptomatology of the stomach, and here we find such matters as the appearance of the tongue as a symptom of gastric disorder, derangements of appetite, pain, acidity, flatulence, vomiting, &c., ably and concisely treated. We would in this chapter especially draw the readers attention to the tables introduced as pages 44 and 61. In the first of these are summed up the chief points of distinction between acidity from fermentation, and acidity from hypersecretion of the gastric fluid; in the second table are presented, in two separate columns, the diagnostic differences between gastric and cerebral vomiting.

For purposes of ready reference by the busy practitioner, such tables are of great value, and they form, moreover, an excellent way of impressing these important distinctions on the mind of the student. Here we believe Dr. Fox follows his own admirable teacher of physic at University College, who, whenever he came to insist strongly on certain well-defined distinctions in the diagnosis of two morbid states, would always direct his students to divide the page in their note-books into two columns, and place at the top of one column the name of the one morbid condition, at the top of the other column the other, and this done the professor would proceed to fill up the two columns with the symptoms constituting the differential diagnosis of the two morbid conditions.

The chapter on neuroses of the stomach is one on which evidently much labour has been spent, as the immense number of authorities quoted in the foot-notes prove. For the relief of neuralgic pain of the stomach, Dr. Fox thinks highly of the carbonate of iron, but the dose of this remedy should not exceed five grains, as larger doses often provoke colic and intestinal disturbance. This advice, with respect to the dose of the ferri. carb., backed, too, by the authority of Trousseau, is not uncalled for, as some practitioners increase the dose of carbonate of iron enormously, till their patients actually get intestinal obstruction from masses of insoluble carbonate collecting in their bowels.

Opium, and the nitrate and oxide of silver, are favourably spoken of as remedies for the cure of nervous pain in the stomach. Bismuth and magnesia only find their opportunity when there is hypersecretion or acidity; the combination of bismuth with hydrocyanic acid is very good when any inflammatory state is present to complicate the nervous disturbance.

We would especially draw attention to chapter 7, on chronic inflammatory dyspepsia, or chronic catarrh of the stomach. The author believes that chronic catarrhal inflammation of the stomach, or chronic gastritis, embraces a large number of the cases of obstinate chronic dyspepsia. "It includes," in the author's opinion, "many of the disorders which have been ranked as irritative dyspepsia, and even some which have been placed among nervous affections of the stomach with morbid sensibility, a condition which, in mucous tissues, is much more commonly the result of minor degrees of inflammatory action than of mere derangements of innervation."

At page 192 is given a table exhibiting the principal diseases with which either acute or chronic catarrh of the stomach has been found associated in 100 cases.

The table shews how common chronic catarrh of the stomach is in connection with phthisis, and also with all those diseases which have a tendency to cause obstruction of the venous circulation. These observations concur entirely with those that had been previously made by Dr. Handfield Jones.

Among the most prominent causes of chronic gastric catarrh Dr. Fox places the habit of drinking undiluted spirits.

The last chapter (viii.) in Dr. Fox's work, is one of some six or seven pages on the diagnosis of the various forms of dyspepsia; the points of difficulty in this matter are clearly pointed out, and the method of coming to a distinctive diagnosis indicated.

In this chapter we would commend to notice the hints given for the diagnosis of nervous disturbance of the stomach, "a matter often of great difficulty," but some of this difficulty, at any rate, will be diminished to any one who will make himself familiar with the instructions given by Dr. Fox.

Having now gone through this useful work, we have only to add that in the next edition we shall hope to have rather more of the author's own personal experience, which we know is by no means inconsiderable, on the value of the various methods of treatment, as well as on other points. None, certainly, can say that Dr. Fox has in this book at all claimed for himself anything that belongs to others, for he has in the most impartial way, done justice to all others who have worked in the same field with himself.

MANUAL OF MATERIA MEDICA.

Of Churchill's favourite manuals, Royle's Materia Medica has held its place for years as one of the best. We have constantly employed it since it first appeared, and can, therefore, speak with experience of its value. The fourth edition was arranged in accordance with the British Pharmacopœia of 1864, and has, therefore, become, to some extent, obsolete. We are, therefore, very glad to welcome a fifth edition,[1] and to find it remodelled on the second edition of the British Pharmacopœia of 1867. We do not pretend to have verified all the changes, but so far as we have looked into the manual we are quite

1 On the Diagnosis and Treatment of the varieties of Dyspepsia, considered in relation to the pathological origin of the different forms of indigestion. By Wilson Fox, M.D. Lond., F.R.C.P.; Holme Professor of Clinical Medicine at University College London, and Physician to University College Hospital. 2nd Edition. Pp. 247. London: Macmillan.

1 Manual of Materia Medica and Therapeutics. By J. Forbes Royle, M.D., F.R.S., and F. W. Headland, M.D. London: J. Churchill and Sons.

satisfied. Dr. Headland's name as joint author is a guarantee that nothing has been omitted that the student can fairly look for.

SQUIRE'S COMPANION.

Little more than half a-year ago, we commended to our readers the fifth edition of Squire's Companion to the British Pharmacopœia, and pointed out a few of the excellencies with which the work abounds (MEDICAL PRESS AND CIRCULAR, Nov. 13, 1867). We have now to announce that in spite of a reprint of the fifth having been necessary, that has been exhausted, and Mr. Squire now presents us with the sixth edition of his work[1], which he has taken the pains of, to a great extent, re-writing. It will be acknowledged on all hands that when a work has become almost a necessity to every one engaged in prescribing or dispensing, it is an advantage for new editions to be frequently called for, provided the author will take pains to avail himself of everything that transpires in the interval. This Mr. Squire has most conscientiously done, and inasmuch as the additions and improvements he has introduced are very numerous, and must have cost him unusual trouble, we tender him our best thanks for the perfecting process to which he has submitted his volume. Of course the additions made must be of the non-official order, but these are of the most useful kind. They are scattered throughout the work, and, therefore, not easy to estimate, but we have traced changes on between fifty and sixty pages—quite enough this to show the extreme care with which the edition is revised.

It being impossible to give an idea by enumerating a few of these, we pass to other points. We now find for the first time an attempt to describe the colours and characters of the liquid and solid preparations. For this purpose, Mr. Squire used as standard preparations the collection he placed in the Paris Exhibition, and which may now be inspected in the museum of the London College of Physicians. Some underwent change during the ten months they were in the exhibition, and in each such case this is mentioned—information that may not only be useful to the committee that may have to revise the next British Pharmacopœia, but will serve as a caution to those who are studying the characters of drugs. Then there is the index, to which, in books of this kind, we always look. It is extended from 39 to 50 pages, and must be by so much more useful. Again, every page of this index has between head-lines these words—"Official names in Roman; all others in italics." This will remind the prescriber on every occasion on which he may turn to it, that the names in Roman letters are those used in prescribing according to the national pharmacopœia. It is, therefore, an addition which will be received with thankfulness by all who still find the old names stick to their memories, or who are confused by the many changes in names that have been made.

There were a few other points we had intended to name, but we have said enough to show that Mr. Squire is evidently determined to retain for his book the good name it has won. We need only add that the additions and improvements are well worth the increase in the price it has been necessary to make.

MEDICAL SOCIETY OF LONDON.—MAY 18, 1868.

Dr. RICHARDSON, F.R.S., President.

THIRD EXTRAORDINARY MEETING.

THE following gentlemen were admitted Fellows by the President:—Dr. William Evans, Dr. David Bell, Dr. J. T. Powell, and Dr. Wane.

Dr. HENRY DICK showed Schäefus' egg-tester, and remarked that its construction was based on the same principle as the endoscope. He also exhibited an endoscope for testing eggs with thick shells, which could be also used for surgical examinations of various parts of the body.

The PRESIDENT exhibited a lamp in which magnesium was employed, and by the use of which he had been enabled to see through the hand of a man. He thought such an instrument might be valuable for diagnostic purposes, such as in exploring abdominal tumours, &c., and in defining the outlines of various organs.

Dr. OPPERT related a case of visceral syphilis. The patient was a child who, when six months old, was infected by a nurse who had a chancre on her nipple. The child got a chancre on the tongue, and subsequently secondary eruptions appeared. The child died seven months after, and at the post-mortem examination white gumreta were found in the lungs, containing an abundance of small cell element.

Dr. THOROWGOOD showed a biliary calculus found—post-mortem—in the gall-bladder of a woman. The point of interest of the case was that during life there were no symptoms at all of gall-stone.

Mr. J. F. PURVIS, of Greenwich, also showed a biliary calculus two inches in length, three and a quarter inches in circumference, and weighing four drachms thirty-nine grains. In this instance the patient had suffered most severely during its passage ten years ago, but was now alive and well.

Mr. W. H. DAY exhibited a biliary calculus the size of a linnet's egg. An interesting and long discussion ensued, at the conclusion of which it was arranged that the subject should be brought before the Society in the form of a paper.

Dr. SEDGWICK read a paper on laryngeal cold. He gave the results of an extended investigation of the Registrar-General's Report. The result was that bronchitis was most fatal when the mean temperature was low, laryngitis and croup when the extreme range of temperature was great.

The question of the registration of disease was then fully discussed, and the Council were instructed to take the subject into consideration.

Dr. DAY, of Stafford, read a paper on "the Spinal Origin of Rheumatism." He commenced by pointing out that the late Professor Mitchell, of Philadelphia, was the first to entertain this view. Dr. Day said that in every instance of acute rheumatism he had detected some amount of spinal tenderness. He treated his cases by cupping and blistering the spine, and was quite satisfied with the results. He related a case of severe acute rheumatism, which had been cured in eleven days. In conclusion, he pointed out the complete compatibility of his views, and the theory propounded by the President, of the nerve resistance of force.

In the discussion that followed, Dr. CHAPMAN said he had treated cases in this way with great success.

Dr. ROUTH thought that the benefit in the case narrated was due to the purgatives given.

The PRESIDENT spoke of experiments that he had made some time ago with lactic acid. He had always found acidity during rigor mortis. He had found that so long as there was a tonic action with relaxation, there was no acidity, but as soon as death came there then also came acidity.

Mr. DAY replied at some length, and the meeting adjourned.

Correspondence.

THE TURKISH BATH IN THE TREATMENT OF DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have lately perceived with pleasure that, in the spirit of progress and fair play, you have opened your valuable columns for the record of cases treated by the Turkish bath.

Though I could furnish you with innumerable cases treated successfully by the bath after the failure of all other remedies, I forbear at present from doing so, but I cannot permit to pass without comment the introductory observations of Dr. Butler on the interesting cases published by him in your number of the 15th instant, wherein he says:—

"In Dublin, perhaps, more than any other city in the world, is the use of baths in any form regarded with a cold and passive indifference, which certainly cannot be due to their want of real merit as curative agents, nor yet to any deficiency of appreciative intelligence (if I may use the expression) on the part of the Dublin practitioners, a fact which their universal reputation proclaims. And yet, that such is in reality the case, I have upon the authority of one of the most venerable, and at the same time illustrious practitioners in Dublin or any other city. *I regard the present apathy of the profession on the subject not to any hostility upon their part to the use of baths grounded upon physiological or scientific data, but to the fact that up to the present the subject has never been brought under their observation;* nor, I presume, are the majority aware that there is an establishment in Dublin at present second to none in the United Kingdom, and where every facility is afforded for fully testing the value of the different descriptions of baths."

May I respectfully ask what part of the world Dr. Butler has been living in for the last twelve years, during which the press has groaned under the numerous publications which from

[1] Companion to the new edition of the British Pharmacopœia (1867). By Peter Squire, F.R.S. 6th edition. London: J. Churchill and Sons.

time to time have issued from it on the bath. Does Dr. Butler forget Sir D. Corrigan's famous attack on the bath some ten years ago, and the great publicity given to that attack at the time? If medical men are ignorant of the numerous cures resulting from the bath, it is partly because, in their pride of knowledge, they will not investigate its merits, and partly because medical journals have hitherto as a rule studiously refrained from giving publicity to them, or opening their pages to the discussion of a subject of such paramount importance to the profession and the public.

In conclusion, I would refer Dr. Butler and your readers to the following extract from Mr. Spencer Wells' interesting lecture delivered to the pupils of the surgical class at the School of Medicine adjoining St. George's Hospital, on the 31st October, 1860, and published in the *Medical Times and Gazette* of November 3rd, 1860:—

"But lately a very important addition has been made to our means of preventing and treating disease by the revival of the Turkish or ancient Roman, hot *air* bath. Our baths, though unworthy of the idea that we are now attaching to the word bath, hitherto have been water or watery vapour; now we have hot air. You will see at once the great importance of this distinction, when you reflect that, in the one case, the heated body is surrounded by dry air, which must favour the exosmosis of the watery portion of the blood through the coats of the cutaneous capillaries, and the endosmosis of oxygen, and at the same time must favour evaporation; while, in the other case, the body is either immersed in water, which would be absorbed in place of oxygen, while evaporation would be checked,—or it is surrounded by watery vapour, which has more or less of the same effect, or by the mixture of vapour and carbonic acid evolved from burning spirit. In the one case, you have exosmosis of fluid, and absorption of oxygen; in the other case, you have neither. We shall see presently that dry air can be supported to a far higher degree of heat than air which contains much moisture, so that we can order baths of far higher temperatures than we ever thought of before. *All this you should be acquainted with or you will find your patients know more about it than you do yourselves, and nothing can be conceived more damaging to your prospects of professional success.* If you hope to succeed, you *must* keep ahead of your patients in the knowledge of everything relating to their health. Now that hot air baths are springing up in all directions, the public are crowding to them, and crying out for information about them. The first bath in this kingdom was erected by Mr. Urquhart, at Dr. Barters' establishment, near Cork, in 1856."

I cannot refrain from observing that if the profession had wisely profited by the sound advice above given, Dr. Butler would have been spared the painful necessity of commenting on their "cold and passive indifference" to a matter so vitally affecting the progress of sound therapeutics; nor would Sir Thomas Watson have been lately obliged to speak in the following terms of the present condition of the healing art:—

"Certainly the greatest gap in the science of medicine is to be found in its final and supreme stage—the *stage of therapeutics.* We want to learn distinctly what is the action of drugs, and of *other outward influences*, upon the bodily organs and functions—for every one now-a-days, I suppose, acknowledges that it is only by *controlling or directing the natural forces* of the body that we can reasonably hope to govern or guide its diseased action. To me it has been a life-long wonder how vaguely, how ignorantly, how rashly, drugs are often prescribed. We try this, and, not succeeding, we try that, and, baffled again, we try something else; and it is fortunate if we do no harm in these our tryings. Now, this random and haphazard practice, whenever and by whomsoever adopted, is both dangerous in itself, and discreditable to medicine as a science. Our profession is continually floating on a sea of doubts about questions of the gravest importance. Of this the evidence is plentiful and constant.

. . . . . .

"I say this uncertainty, this unseemly variation and instability of opinions, is a standing reproach to the calling we profess. It has shaken the faith of many men, of men both able and thoughtful. and driven them to ask themselves *whether any kind of medication*, other than the *vis medicatrix naturæ*, is of any real efficacy or value."

My large experience convinces me that air and water, modified by temperature, and scientifically administered, efficiently fill the gap alluded to.—I am, sir, your faithful and obedient servant,

RICHARD BARTERS, M.R.C.S.E.

April 21, 1868.

Medical News.

FELLOWSHIP OF ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College having undergone the necessary examinations for the Fellowship were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and at a meeting of the Council, on the 11th inst., were admitted Fellows of the College:—Messrs. James Nicholls, Chelmsford, diploma of membership, dated October 15, 1852; William Robert Cornish, Her Majesty's Indian Army, December 17, 1852; and John Warrington Haward, Westbourne-park, May 7, 1863, students of St. George's Hospital. William John Palmer, Her Majesty's Indian Army, June 17, 1853; Edward James Pollock, Old Cavendish-street, July 30, 1863; and Hutchinson Royes Bell, Harley-street, November 19, 1863, of King's College. Edwin Clement Bensley, Her Majesty's Indian Army, November 5, 1858; Samuel Grose, Royal Marines, April 11, 1859; and William Warwick Wagstaffe, Kennington-road, April 29, 1864, of St. Thomas's Hospital. Thomas Richard Jessop, Leeds, July 19, 1859; John Foster, Bradford, Yorkshire, July 19, 1859; and John Sykes, Leeds, May 8, 1866, of the Leeds School. Matthew Algernon Adams, Maidstone, July 15, 1859; and Henry Greenway Hawse, Maze-pond, January 25, 1865, of Guy's Hospital. William Birket Procter, Bradford, Yorkshire, May 7, 1854, of the Middlesex Hospital; and George Farr White, Ryde, Isle of Wight, July 10, 1857, of the University College. It is added that all the candidates who presented themselves on this occasion passed the examination for the above distinction.

ST. MARYLEBONE WORKHOUSE.—At the request of Sir James J. Hamilton, Bart., crown churchwarden of the parish of St. Marylebone, the Earl of Devon, President of the Poor-law Board, in company with Sir Michael Edward Hicks Beach, Bart., M.P., Poor-law Secretary, visited the new casual and chronic wards of the workhouse of this parish, to which we lately drew attention, and which were erected from the designs of Mr. Saxon Snell. The Earl, who was accompanied in his inspection by Sir James J. Hamilton, the Rev. C. J. Phipps Eyre, the rector; Dr. Brewer, chairman of the Metropolitan District Asylum Board, and several of the guardians of St. Marylebone and other metropolitan workhouses, expressed his warm approval of the admirable arrangements made by the guardians of this parish for the comfort of their aged and infirm poor, and of the extreme cleanliness, order, and regularity which prevailed throughout the whole of this extensive establishment.

SCOTTISH UNIVERSITIES' UNION.—This association was originally established to promote social intercourse among gentlemen of literary tastes who had been educated at the Scotch Universities. Its first president was the late Rev. F. A. Cox, M.A. Edinburgh, and LL.D. Glasgow, author, amongst other works, of a volume on "Bible Antiquities," forming the article on that subject in the Encyclopedia Metropolitana, and joint worker with Brougham in the establishment of the University College, London. He was succeeded by various literary alumni of Scotch Universities, the last of whom were Sir David Brewster and Lord Brougham. Similar in constitution and aims with the Social Science Association, it has been thought likely that now when the Scottish Universities are to be enfranchised this society might prove a sort of united convocation for all their members. Sir James Y. Simpson, Bart., has consented to be one of the vice-presidents, and Dr. George W. Balfour has been appointed honorary local secretary for Edinburgh. A secretary and treasurer will also be appointed in Glasgow, Aberdeen, St. Andrews, London, Dublin, and wherever else it may be thought desirable. In Dublin, Sir Dominic Corrigan, Bart. (an M.D. of Edinburgh), has accepted the chief post, and is one of the vice-presidents of the year. A general meeting is hoped to be held before the close of the year, at a place afterwards to be agreed upon, when papers will be read by distinguished alumni on subjects connected with the universities and education. Further particulars will be advertised.—*Courant, June 6th.*

PROFESSOR JOSEPH PERKINS has resigned the chair of Obstetrics in the Medical Department of the University of Vermont, at Burlington, and is succeeded by Dr. E. S. Dunster, editor of the *New York Medical Journal.*

Lecture.

CLINICAL LECTURE ON INSUFFICIENCY OF THE AORTIC VALVES.

By S. JACCOUD, M.D.,

PHYSICIAN TO THE HOSPITAL OF ST. ANTOINE, PARIS.

TRANSLATED BY JOHN COCKLE, M.D., M.A.

(Continued from page 516.)

Aortic obstructive disease, of special frequency in old subjects, is usually accompanied by senile degeneration of the arteries; the characters of the pulse are, consequently, necessarily complex. But, the following trace, from a young man, æt 19, suffering from aortic obstruction (probably congenital), will show the true pulse of this form of disease. In this youth, there is considerable hypertrophy and energetic impulse of the heart; if you take note of this circumstance, you will find that the pulse is small, but perfectly regular (a fact, Marey has already pointed out), and the dicrotism of the line of descent is scarcely marked (see Trace 7, p. 514). Observe at the summit of the curve a slight level, which reminds us of Trace 4.

Whenever aortic obstruction coincides with mitral insufficiency, it appears that the former lesion causes the irregularity of the pulse, special to the latter, to disappear in part. It may be supposed that the aortic obstruction, imposing fixed limits to the ventricular discharge, no longer permits the passage of an alternation of very small or very large waves of blood; but, a variable volume of wave at each contraction of the heart, is one of the causes of the irregularity of the mitral pulse.

The following trace was taken from a female patient, æt. 69, suffering from aortic obstruction and mitral insufficiency (see Trace 8, p. 514). The pulse though small, is regular; the level of the curve is clearly marked, and the line of descent literally broken.

The traces, next exhibited, relate to mitral disease.

Marey insists, with reason, upon the irregularity of the pulse of mitral insufficiency; it is, according to him, the pathognomonic character. This irregularity is complete without exhibiting those regularly periodic variations common to senile degeneration of the arteries, and the tracings he depicts of this form of pulse, fully justify his assertion. I accept it, for my part, with one restriction forced upon me, from my own observations. When mitral insufficiency reveals itself only by a murmur at the apex during the first period; when it produces no disorder of the peripheral circulation; in a word, when the signs of asystolie are entirely absent—the pulse may be perfectly regular, smallness and length of the line of descent being then its chief characteristics. But, however little the artificial equilibrium of the circulation is disturbed, however slight the extent to which the signs of *asystolie* appear, irregularity of pulse shows itself in the form assigned by the founder of sphygmography in France. The following traces justify my reservation (see Traces 9 and 10, p. 514).

The first trace was taken from a young girl aged 18, who suffered, at the age of 15, from an attack of acute rheumatism associated with endocarditis. From this period she has been subject to palpitation, and had, on one occasion, swelling of the legs. At the present time the mitral disease, perfectly compensated, reveals itself only by a rough murmur at the apex of the heart, during the first period. There exists no anæmic murmur at the base to confuse and complicate the case. The pulse is small, very slightly dicrotous, but still perfectly regular. Similar remarks are applicable to the trace 10, taken from an adult male suffering under like conditions. In this case, the dicrotism only has disappeared, whilst in mitral insufficiency with irregular pulse, the smallest pulsations retain very marked dicrotism. The subjoined figure exhibits the perfect type of this form of pulse (see Marey. Fig. 202, page 514).

I do not possess a trace of pure mitral contraction, but a patient, who has been for some time in the hospital, affords us an opportunity of studying the pulse of contraction combined with insufficiency of this orifice. In the case of this man, æt. 56, the double lesion reveals itself by a double murmur at the apex, the aortic orifice remaining intact. Upon his arrival at the hospital, this man was in a most alarming state of complete *asystolie*, the rhythm of the heart's action, was not detectable; and the pulse, almost reduced to a thread under the finger, could not impart movement to the sphygmograph. Under the influence of appropriate treatment, in which digitalis in 15 grain doses daily, played the principal part, these accidents were modified. In about 48 hours the pulse had acquired sufficient force to be registered with the following result (see Trace 11, page 514).

Two days later, the effect of the digitalis was still more decided, the pulse had acquired greater amplitude, but its fundamental characters were the same as shown in the trace of to-day (see Trace 12, page 514).

The dominant character of these two traces, is the irregularity, an irregularity of the same kind as that which characterises simple mitral insufficiency, with dicrotism of the smaller pulsations. Indeed, even at the present time, I know of no constant character which will enable us to distinguish, at first sight, the trace of simple mitral insufficiency from that of insufficiency with contraction. In a large proportion of cases we may take for guidance the modification pointed out by Marey. Contraction tends to suppress the characteristic irregularity of insufficiency; but the preceding fact, and many analogous ones which I have observed, do not authorize me in affirming the constancy of the result.

This discussion will not, I trust, have been uselessly made. I now return to the patient whose case was the subject of this lecture, as its clinical interest is not yet exhausted.

I have mentioned to you that this woman contracted cardiac disease more than fifteen years ago, as a consequence of acute rheumatism, and during this long period she has suffered no other inconvenience than that of palpitation, rather frequent attacks of bronchitis, and slight œdema of the ankles, when during the day she had undergone more than ordinary fatigue. These slight accidents, however, have never compelled her to suspend her duties. It is only now that the state of her heart has caused her to apply for relief. Upwards of fifteen years she has suffered, without distress, from aortic insufficiency; then, all of a sudden, this affection, mute hitherto, has given tongue, and, by an abrupt outburst, lighting up the accidents which follow in its train, has brought this woman to the serious condition I described at the commencement of the lecture.

Why has all this occurred? Why this sudden storm succeeding fifteen years of calm? This is the question I propose to examine. It obtrudes in the same terms, in all the organic diseases of the heart, and you may easily apply to other cases, the special results of aortic insufficiency.

The preceding question resolves itself into two distinct problems. How did it happen that the disease produced no accident before? Why was the immunity only temporary?

The reply to the first question is easy; it would present itself almost spontaneously to your minds if you reflect upon the disturbance that incompetence of the aortic orifice engenders in the mechanism of the intra-cardiac circulation. At the instant of the ventricular diastole, when the blood-wave, compressed by the elastic reaction of the aorta, should pass entire towards the peripheral vessels, the sigmoid valves remain unclosed, and a portion of the blood falls back into the chamber it had just quitted, as a necessary result. The quantity and force of the reflux are conditioned upon the diameter of the size of the chink, and the systolic energy of the aorta. Imagine matters, then, to continue in this state; imagine that no new condition intervenes to compensate the influence of such disturbance—the circulation would speedily become completely obstructed in the cardiac cavities, and the heart would cease to act. Picture well to yourselves what happens. The left ventricle possesses a definite capacity—estimate it at 10; but, as a consequence of the non-closure of the aortic valves, the quantity it would hold is no longer 10, but 12, for example. But if no change occurs; if the original capacity of the chamber remains the same, it could not find accommodation for the overcharge of blood; the left auricle, therefore, could no longer thoroughly empty itself, and the stasis would extend, step by step, to the right cavities of the heart by the intermediation of the veins and pulmonary artery, until the engorgement—or, to use a better term—the excentric pressure of the blood contained in the cavities, overpowers the contractile force of the heart, in which case the organ stops before the obstacle it cannot conquer. Consequently, in order that the disastrous results of aortic incompetence may admit of compensation, it is above all things necessary that the ventricle should permit distension, and dilate to such an extent as to be enabled to accommodate the surplusage of blood. In a word, the capacity of the containing vessel must be adequate to that of the fluid to be contained. This is what really happens, and dilatation of the left ventricle is the first mode of compensation in aortic insufficiency. This, however, is insufficient, and, limited to this resource, the compensation would be but transient. Glance again at the numerical figure used shortly before. Assume the dilated left ventricle equal to 12 instead of 10; still, if its propulsive power remains equal to 10—that is to say, if the contractile force of the muscle is unable to project into the aorta a column superior to 10, matters would not be improved, despite the compensative dilatation. The import is 12, the export 10. It is evident, therefore, that a residue of 2 remains in the cavity of the ventricle, and additions being made in arithmetical progression during each systole, the transit of blood from the auricle into the ventricle would speedily become seriously modified, and a great aggregate of results of cardiac disorders, uncompensated, would accrue. Defect of propulsive force lessens arterial tension and, as a result, causes diminution or suppression of the secretions, and notably, that of the kidney; at the same time, the obstruction offered to the passage of blood from the auricles increases the tension of the veins; hence, dropsical effusion, and all forms of congestion. The secondary forms of disorder induced by organic lesions of the heart acknowledge no other cause that this reversal of the respective tension of the arterial and venous systems. In the normal state, the arterial tension far transcends that of the veins; in the pathological state, which we study, the difference is annulled, or manifests itself in the inverse direction, the marked phenomena of asystolie and of cardiac cachexia, acknowledge no other pathogenic condition. Wherever the seat of the cardiac lesion may be, the moment such lesion is no longer compensated, it acts by the same mechanism; diminution of arterial and increase of venous tension—all, I repeat, is here. Mere dilatation of the left ventricle cannot furnish a desirable compensation. It is of paramount necessity, that the propulsive power should be proportionately increased; if the ventricle contain 12, it must propel 12, and this condition becomes realised by the hypertrophy of the cardiac muscular tissue. The propelling agent augments in power at the same time that it increases in capacity; from this moment, compensation is established, and may last for years. Dilatation and hypertrophy of the left ventricle furnish, then, the solution of the first problem; but how does it happen that this condition is unproductive of mischief?

When the compensation thus established is perfect—that is to say, when there exists a due proportion between the dilated hypertrophy on the one part, and the volume of the retrogressive wave on the other, the disease is literally mute, those so affected are sensible of no injurious effects—are not, strictly speaking, to be considered sick. But the compensative influence does not, in all cases, respect these favourable limits. It may stop within, or may extend beyond them. In the first case it is incomplete; in the second, it is exaggerated.

By imperfect compensation, I understand that degree which, though sufficient to prevent *asystolie*, properly so termed, permits, nevertheless, the development of phenomena more or less serious. I should not pause upon this particular stage were it not liable to lead to a serious therapeutic error, in the following manner:—The phenomena alluded to, consist of more or less frequent paroxysms of palpitation, a tendency to syncope in the erect position, and, more particularly, on sudden change from a recumbent to an erect position; there exist, moreover vertigo, aural tinnitus, optical disorder, and the face usually pale, is subject, several times daily, to sudden flushings, of which the patient much complains, designating them as "puffs of heat." Conjoined with these phenomena, the pulse exhibits the ample and bounding character of aortic insufficiency, and if the clinical observer were not prepared, he would infallibly be misled by the sug-

gestion of the patient, and refer the symptoms to habitual cerebral congestion. Treatment is adopted in accordance with this view ; venesection is employed, and the practitioner is quite surprised at the inutility of the plan; the more active his treatment to quell this persistent congestion, the more the symptoms increase, the pulse becomes more and more ample, more and more bounding, the palpitation and syncopal tendency increase, and at length the nutrition of the ventricle becoming seriously impaired, it is longer able to impel its contained blood, and asystolie supervenes. The compensation was imperfect, the treatment has destroyed it. And why? Because the congestion, the assumed source of all the mischief, had no real existence, and because the symptoms experienced by the patient were mainly due to cerebral anæmia. The compensation was imperfect, that is to say, the propelling power of the ventricle was not in due proportion to the column of blood to be propelled ; the cerebral circulation then would be the first to manifest disturbance, because the blood, to reach this centre, ascends against the force of gravity ; power of cardiac action is here essential. From want of this power, arose the tendency to syncope in the erect position, vertigo, optical disorder ; and from this defective cardiac power, again, arose the ill effects of spoliative treatment.

So far then from following the erring indications furnished by the pulse, it is necessary to seek, from other symptoms, the true cause of the accidents observed. You will, then, discover that the impulse of the heart is weak, and that its beating possesses but little energy ; you will, also, seek in vain the thrill and arterial jerking; and, finally, you will find that the distressing symptoms complained of, are less marked or even absent, so long as the patient remains in the recumbent position. From these signs you will recognise the feebleness of the ventricular contraction, and the existence of imperfect compensation. What is really required in such a case is a tonic treatment assisted by invigorating diet. Extract of bark, to the extent of 30 or 40 grains daily, preparations of steel, and red wine, in quantity proportional to the habits and condition of the patient, such are the best means to be resorted to. I have many times witnessed, in similar cases, the efficacy of this treatment, to which I add a cup of infusion of quassia, to be taken in the morning, fasting. This agent excites organic contractility, and this property which recent investigations have disclosed to us, is, here, of real utility.

Tea and coffee are, also, important agents by virtue of their exciting influence over the nervous system. In cases where aortic insufficiency is imperfectly compensated, the ordinary symptoms occasionally acquire an intensity sufficient to create alarm ; under such circumstances we cannot wait for the usually slower effects of the measures recommended, but must, at once, resort to stimulants of a more energetic and prompt description. Æther, Hoffman's anodyne, in doses of 10 or 15 drops, repeated according to circumstances ; acetate of ammonia in doses of one or two fluid drachms, in a julep sweetened with syrup of æther. Lastly, the ammoniacal spirit of *Sylvius*, (30 or 40 drops in infusion of mint), are, now, specially indicated. The use of these agents is to be pretermitted directly the symptoms improve, and the tonic treatment recommenced, and used with the requisite tact to combat the same source of danger, to wit—imperfect compensation.

Exaggerated compensation presents a totally different picture ; strong impulse, violent beating of the heart, jerking of the arteries, bounding and vibrating pulse, congested face, constant headache, tinnitus aurium, sleeplessness, and frequent attacks of hæmorrhage, especially from the nose. Such are the principal characters of this condition ; they are those of the form of hypertrophy termed active ; but the fact of the aortic incompetence, indicates a different plan of treatment.

Despite the signs, so marked, of arterial fluxion, it is far from good treatment to take blood from this class of patients. The condition immediately consequent upon the momentary relief thus afforded, is precisely similar to that of the mechanical disorders, inasmuch as the blood removed is almost immediately replaced by water, so that nothing is gained by the operation. On the other hand, by creating an artificial hydræmia, the risk is incurred of seriously weakening the heart's action, and hastening the advent of that disturbance of its nutrition which, sooner or later, terminates in *asystolie*. Furthermore, it would be impossible to affirm that the patient is not of a constitution liable to fall into a state of syncope from ordinary venesection, and this doubt alone ought to deter us from such a measure ; for, if syncope is always an alarming accident in cases of organic disease of the heart, it is greatly more so in cases of aortic insufficiency. Venesection is then, as the rule, justly proscribed in the treatment of this disease, and is only to be resorted to under some great, though temporary emergency, such as cerebral or pulmonary congestion, or in a case of severe hæmorrhage. In order to diminish the exaggerated compensation and over-action of the heart, means must be employed whose action though slower, is more durable, and less dangerous. Mental and bodily repose, relaxation from business pursuits and fatiguing amusements, moderate diet, composed almost exclusively of milk, vegetables and white meats, constitute the best hygienic plan. Various therapeutic agents may aid its influence ; hydrocyanic acid, cyanuret and iodide of potash. I have in such cases, on two occasions, derived advantage from this latter remedy, the special sedative action of which does not seem to be sufficiently known. But the grand remedy is digitalis, and, in my opinion, the best form is an infusion of the leaves. Under the special circumstances we have been considering, the action of this agent is certain ; frequently, after the very first day, the beating of the heart is less violent, the sense of oppression, consequently less distressing, the pulse diminishes, and loses its vibrating character, and after forty-eight or seventy-two hours, the case undergoes considerable amelioration. The result is still more striking if the action of the heart is, at the same time, violent and irregular, though this condition is rare in simple aortic insufficiency. But do not, gentlemen, abandon yourselves to a false security. Like all other powerful agents, there are dangers attending the use of digitalis it is important to be aware of. Whether you commence with too powerful a dose or, inordinately, prolong the maximum dose I have prescribed, you will suddenly pass from the therapeutic to the toxic action of the agent, with the following result :—with, or without gastro-intestinal phenomena, with or without cerebral phenomena, the action of the heart weakens, and beats with unusual frequency ; the pulse becomes small, rapid, and compressible ; phenomena of venous *stasis* appear, and the face acquires a cyanotic hue. In a word, you have an artificial *asystolie*, which, if prolonged, will destroy the patient as surely as the spontaneous form.

There has been, nay, is still, much discussion touching the mechanism of these phenomena. The pathologic interpretation necessarily varies according to the view adopted of the function of the *par vagum* ; whether it be an inhibiting or moderating cardiac nerve, or, whether of the excito-motor class ; and, also, according to the part the sympathetic nerve is supposed to play in the innervation of the heart. The divergence of opinion is, happily, unimportant, since, if we do not know, with certainty, what the modification may be which substitutes a toxic for a therapeutic action, we are perfectly sure what the disorders produced in the circulation, are, by this primordial modification, and knowing this, we are quite cognizant of the artificial *asystolie*, produced by digitalis. Science is indebted to Traube for this important fact. By a series of delicate experiments, the distinguished Professor of Berlin has discovered that the effect of digitalis, in large or toxic doses, is to diminish sensibly the arterial tension and to augment the frequency of the heart's beat, so that, digitalis acts, under such circumstances, in the same way as cardiac lesions non-compensated, which, you will remember, commence by inversing the normal tension in the

two circulating systems. It is, therefore, no matter of surprise that the symptomatic phenomena are the same in both cases.

You may suppose, therefore, that the administration of digitalis requires, in such cases, unceasing watchfulness. Once the sedative therapeutic effect obtained, it is needful to examine, several times daily, the impulse of the heart and the state of the pulse, observing at the same time the nature of the respiration and the tint of the complexion, and upon the appearance of the very earliest sign of weakness, or cyanotic tint, either suspend the medicine or lessen the dose. Such examination should be repeated at short intervals, because, in patients who have been for some days under the influence of the drug, the toxic effects appear, in general, very abruptly. Under such delicate circumstances, no means of information ought to be omitted ; I would therefore advise you, daily, to ascertain the amount of urine excreted ; this is a sure index, and one which has never misled me. So long as the secretion increases under the influence of the remedy —so long as the amount, once brought to its normal standard, only oscillates within narrow limits, there is no danger ; but when the diet and the medicine, remaining unchanged, the quantity of urine secreted in 24 hours again diminishes, and returns to the quantity passed at the commencement of treatment, feel assured that the arterial tension begins to lessen, and that artificial *asystolic* is imminent ; discontinue the treatment without delay. This sign sometimes antecedes any appreciable weakness of the heart and pulse, and is the reason why I cannot too urgently enforce the necessity of its observance.

As a consequence of some theory I am unacquainted with, aconitine has been vaunted as a substitute for digitalis, but the researches of *Van Praag* have proved this agent to be untrustworthy ; it will, therefore, be prudent to abandon it. Not so, however, with respect to Cafeine, which, unquestionably, merits a place in the therapeutics of the diseases of the heart. Under the influence of this agent, administered in doses of about 5 to 15 grains daily, in the form of a pill, the heart acquires vigour, its action becomes more regular, and as a necessary consequence, the secretion of urine is increased. When the patient, to whom cafeine is given, is in a state of marked *asystolie*, the effect obtained can be easily followed and measured by means of the sphygmograph, which ought always to be used under such circumstances, if it be desirable to estimate what is being effected.

Cafeine, then, exhibits an action similar to that of digitalis, but, according to my experience, this action, although quite as prompt, is less energetic. The Traces 11 and 12 enable us to appreciate the influence of digitalis in the case of the man in St. Charles' ward, suffering from mitral insufficiency and contraction. The two traces I now show you, demonstrate the positive action of cafeine. They were taken from the same patient. The digitalis was suspended for eight days, a very necessary precaution to observe prior to the institution of a fresh experiment, remembering that the effects of the drug lasted in his case three or four days, at least. During the last three, out of the eight days, the phenomena of *asystolie* were developed anew, the pulse had re-acquired the irregularity and weakness that it presented at the time of his admission into the hospital ; it could, however, be registered with the sphygmograph, as shown in the trace 15 (see Trace 13, page 514.)

Shortly after this trace was taken, four pills, each containing about three grains of cafeine, were given at intervals of two hours. Within twelve hours after the last dose, the pulse had already changed its character (see Trace 14, page 514.)

The irregularity was less, and the amplitude of the pulsation, that is, the force of the cardiac impulse, had visibly increased. But there remains another proof. The patient had only passed seven ounces of urine during the twenty-four hours preceding the administration of the cafeine ; after the dose he passed, in the same space of time, fourteen ounces, and when the dose had been increased to five grains, the quantity of water passed reached 24½ ounces. Cafeine, which may also be administered in the form of a citrate, has then an unquestionable influence, resembling that of digitalis, though less decided. Compare Trace 14 with Trace 12, and you will perceive that the pulse had acquired much greater power under the action of digitalis ; more than this, the effects of cafeine cease, after the discontinuance of the agent, and for this reason digitalis merits the preference. But as patients are found who, in consequence of a special susceptibility of the stomach, cannot tolerate this remedy, it is important to be familiar with the parallel properties of cafeine.

In cases of aortic insufficiency, and in diseases of the heart generally, there exist no other indications for the use of digitalis than those I have pointed out ; sedative and regulator, *par excellence*, of cardiac activity this agent is specially applicable to the following symptoms—over-action or, deficient action of the heart. Digitalis acts, moreover, on the secretion of urine, increasing its amount ; but this result is secondary and simple, resulting from the equalisation of the action of the heart and the increase of the arterial tension.

The indication for the use of digitalis does not exist in the case of our patient, but in order to remedy the mechanical disorder of the circulation, we have employed drastics and tonics ; you have witnessed the efficacy of this treatment. Whether the relief produced will be permanent is another question, to which we shall almost immediately recur.

However perfect the compensation of the cardiac lesions may be, it is but temporary. The artificial equilibrium, by means of which it maintains a circulation nearly normal, may last for years, but it must yield in time, and the change is fatal. The muscular tissue of the heart, compromised as to its nutrition, eventually undergoes regressive transformation, ordinarily of a fatty character, and when this secondary change, the importance of which has been pointed out by Stokes and Paget, has arrived at a certain point, the ventricle, although increased in volume, although apparently hypertrophous, no longer contains sufficient contractile tissue to meet the requirements of the over-action imposed upon it by disease, its impulsive force diminishes, and it empties itself imperfectly ; the evacuation of the venous system is, as a consequence, prevented ; the compensation is destroyed, and, as this result arises from an anatomical condition over which we have no control, the action of the heart must, of necessity, be arrested, and death ensue. It is quite impossible to assign any limit to the time required to produce this degeneration of the cardiac tissue ; the most surprising variation exists in this particular. The seat of disease, and the amount of the obstruction offered to the passage of the blood are, doubtless, of some importance as to the result, but the chief reason of the difference must be sought for in the vital condition of the patient, in the mode of his nutrition, and, consequently, some little in the treatment which has been adopted.

(To be continued.)

Original Communications.

ON TWO CASES OF CEREBRAL SOFTENING.

By W. H. DAY, M.D., M.R.C.P.Lond.,

VISITING-PHYSICIAN TO THE MARGARET-STREET INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE two following cases are of sufficient interest to induce me to place them on record, as exemplifying some symptoms of an unusual character, and among these the absence of headache is rather uncommon. No headache at any time was complained of in either case during illness. The defective vision first attracted notice. In the cerebral affections of young children (acute hydrocephalus for instance) and in the cerebral softening of those advanced in life,

headache is a constant symptom, so constant that its absence may lead us to underrate the importance of the case, even when serious mischief is going on in the brain. In a case of remittent fever, in a young girl who came under my care some years ago, the absence of headache was scarcely to be accounted for, when a post-mortem examination revealed general inflammation of the membranes, and superficial parts of the brain, with effusion into the lateral ventricles, and meningitis at the base of the brain. The head derangement first manifested itself by a sudden and violent convulsion during the convalescent period of the fever, when the skin was cool, and the pulse reduced to 80 beats per minute. A little twitching of the right eyelid had been noticed the day before the attack, but there was no strabismus, vomiting, or dimness of vision present, and the intestinal disorder appeared enough to account for this symptom. The presence of headache is certainly a very frequent sign of cerebral disturbance, but its absence is by no means incompatible with the gravest lesion. The brain is so peculiarly organised that similar results are brought about by the operation of very different causes. Hæmorrhage into the brain, or congestion of its vessels, may paralyse the functions of intelligence, of motion, and of sensation. It may give rise to the most severe convulsions, as in cases where extreme loss of blood has taken place, and the changes cannot be too slight to exert their influence on the delicacy of the nervous centres. A susceptibility to nervous diseases generally, and a quickness and a fertility of imagination, appear to me to solve this explanation of many cerebral affections.

PARALYSIS OF THE THIRD NERVE: RAMOLLISSEMENT: DEATH.

Case 1.—C. W., æt. 35 (May 11, 1862), has suffered the last three weeks from dilatation of the left pupil, with an imperfection of the branches of the nerves supplying the external muscles, so far as to occasion him giddiness in walking, when he shuts the right eye, and attempts to balance himself by the aid of the left eye only. There is lacrymation and injection of the conjunctival vessels, and he complains that the eye is very weak. It does not rise so high in the orbit as the other, and it turns more outwards.

Mr. Bowman thought the third nerve was affected in some part of its course, within the head, and perhaps at its origin. The digestive organs are deranged, pulse regular and good, urine rather high-coloured, and non-albuminous. He was ordered to take a light diet, and two glasses of sherry daily. He also took the following medicine:—

℞ Pil. hydrarg. gr. iss.
„ rhei co. gr. iii., in pilula.

To be taken every night for a week.

℞ Potass. iodidi gr. iv.
„ bicarb. gr. x.
Tinct. gent. comp. ʒi. Aquæ ad. ʒj.

Fiat haustus. To be taken twice a-day—at eleven and four o'clock.

May 17.—The general health was much improved, and the inflammatory redness of the eye was gone. A small blister was applied behind the left ear every third night.

26th.—The pupillary dilatation was less, and the sight stronger, though objects are still hazy.

29th.—The pupil is diminished to nearly half the size it was ten days ago, and were it not that the right pupil is very small, the affected eye would scarcely create notice. He can read ordinary type at the visual distance.

To take, in addition to the mixture, pil. ferri comp. gr. v. twice a-day.

July 30th.—There is very little difference in the appearance of the two eyes; the lens is healthy, and the sight perfect when he looks through a small hole with a 16-inch convex lens.

August 30.—The iodide having been omitted for a fortnight, was again resumed.

September 14.—The eye is certainly weaker, but the general health is very good. The pulse is slow and weak. To omit the iodide, and take the following pill three times a-day:—

Zinci sulphatis ʒss.
Strychniæ gr. j.
Conf. rosæ q. s. Ut fiant pilulæ xxx.

October 14.—He thought his left eye sound, and I saw no more of him till January, 1865, when he was suffering from well-marked cerebral softening. He was much changed in manner, being solemn, serious, and cautious. The left eye was weak, but the pupil was reduced to the size of the right eye. He gradually lost all power over his limbs, and became so feeble that he could not walk, and had to be carried from one room to the other. He was unable to feed himself, and passed his urine and fæces unconsciously.

A sudden attack of apoplexy closed his life in September, 1866.

No post-mortem examination was permitted.

In the following interesting case, the disease undoubtedly remains in abeyance. It clearly shows the influence of remedies to ward off dangerous symptoms, and to encourage the hope that many of these grave affections are within the control of well-directed means.

Case 2.—G. W., æt. 18, by occupation a lapidary, was admitted a patient under the care of Dr. Hawkesley, at the Margaret-street Infirmary for Consumption, on January 30, 1867. He has been ailing for more than a year, though he has continued work till a very late period. There is no history of consumption nor of insanity in the family.

Present state.—Both pupils are dilated, particularly the left which is very large; both are obedient to the stimulus of light; the left eyelid droops slightly, and the ball of the eye is drawn outwards. He cannot read with the left eye, objects appearing confused, and as though enveloped in a mist. He has had several fits, which his mother describes as "fainting fits"; they are probably epileptic. He is short of his age, very thin, and fast losing flesh and strength. He is moody, sullen, and abstracted, and never interests himself in anything. He has a quick feeble pulse, appetite good, tongue clean, very anæmic-looking. The lungs are healthy, and there is neither cough nor headache. He has perfect control over the bladder and rectum. There is probably tubercular disease or softening about the origin of the third nerve. He was ordered good diet, without stimulants, and the following draught three times a-day:—

Potassii iodidi gr. ii.
Ferri amm. citr. gr. iss.
Aquæ ad ʒj.

Fiat haustus—*ter die sumend.*

March 6.—The improvement is extraordinary, the pupils are reduced to an equal and average size, his countenance is less vacant, and he smiles and takes notice of any observation addressed to him. He looks like another person, and is much better in health.

July 6.—He has greatly improved, and his mother considers him quite well. His pupils are of medium size, and there is no apparent difference between the right and left eye. He sees objects distinctly and at the usual distance. He has no headache, and has a bright, cheerful look, which strangely contrasts with his former heavy and unmeaning aspect. He has gained much flesh, and says he feels well and strong. All medicines were omitted, and he left with instructions to apply again if any unfavourable symptoms should return.

ON DISLOCATION AND ABNORMAL MOBILITY OF JOINTS, THE RESULT OF CHRONIC RHEUMATIC ARTHRITIS.

By ROBERT ADAMS, M.D.

(Read at the Meeting of the Surgical Society of Ireland, on the 24th of April, 1868.)

(Continued from page 519.)

Such was the condition of Stafford when I published his case in my treatise on "Chronic Rheumatic Arthritis or Rheumatic Gout (1857)." Since that period up to the

present time, his chronic disease has very slowly but gradually increased, yet was he never disabled altogether from working at his bench as a carpenter, or from taking exercise daily, which he considered beneficial to his general health.

We have here to remark that a few years ago, as our patient was not able to support himself by his work, he gladly accepted of an offer made to him to be admitted as an inmate into Simpson's Hospital in this city, an asylum for those afflicted with gout and rheumatism, where he now resides. At my request he presented himself sometime ago at the Richmond Hospital, in which he had been a patient when his case was published, my colleagues and I had thus an opportunity of examining him, and of comparing his present with his former condition.

He is now about 59 years of age, his left shoulder, represented in Fig. 2, is still more deformed than it was ten years ago, when the drawing was taken, and the arm is still now more susceptible of abnormal movements than it was heretofore.

We can now readily, and without causing any pain to the patient, place the head of the humerus on the dorsum of the scapula.

There seems to be less of the synovial effusion than formerly, but now large foreign bodies can be felt in the joint.

The *right* shoulder joint, as was correctly anticipated by the patient himself some years ago, was seen now to be in an abnormal condition, both as to external appearance and susceptibility of luxation of the head of the bone, nearly similar to the left shoulder before delineated (see Fig. 2, p. 517).

Although those who have studied chronic rheumatic arthritis of the shoulder must necessarily be familiar with the ordinary anatomical characters the tendon of the biceps presents in the dead body as the result of this disease, yet the external signs by which such a change is known in the living, have not hitherto been noticed nor described by any: and to me it would appear that this case of Stafford presents us with a good illustration of the external appearances which are to be expected, when the intra-articular portion of the tendon of the biceps has been destroyed as the result of chronic rheumatic arthritis.

The relaxed condition of the left shoulder-joint in this case probably arose from analogous causes to those which presided over the same condition of the left knee-joint. The synovial effusion, the result of chronic synovitis, with which the disease in both shoulder-joints began, caused an elongation of the synovial capsules, while the loss of the intra-articular part of the long tendon of the biceps had, perhaps, in this case on the shoulder-joint an analogous effect to the loss of the crucial ligaments on the left knee (lesions which we take it for granted have occurred.) The peculiarity of appearance represented by the belly of the biceps muscle (see Fig. 2, C) depends, probably, on this muscle not having its normal origin from the glenoid cavity of the scapula, but from the humerus, at the summit of the bicipital groove, which is some inches lower down.

As to this shoulder-joint of Stafford, if it be permitted to us to speculate on the actual condition of it in a living patient, I would say that I believe that the glenoid cavity is greatly enlarged; that the capsular ligament has a wide attachment above to the coracoid process, and to the anterior margin of the coraco-acromial vault; that the condition called hydrops articuli of the synovial sac exists; that the intra-articular portion of the tendon of the biceps is absorbed altogether, so that the head of the bone can move freely, unrestrained by this tendon, in the widened capsule.

I may here observe that there is a preparation of a shoulder-joint in the museum of this college, which some years ago I considered so remarkable, and such an illustration of chronic rheumatic arthritis, as it affected in an advanced stage the shoulder-joint, that I procured a lithographic drawing of it by Conolly, and have placed it (Plate 2) in the atlas of my treatise on "Rheumatic Gout," because I believe that the case in the catalogue of the museum published 1840, page 397, is merely noticed as "a chronic disease of the shoulder." Still, I must claim the specimen as a most valuable illustration of chronic rheumatic arthritis of the shoulder-joint of long standing; and I do moreover believe that, if the symptoms which the individual to whom this joint had belonged, could have been collected they should have been just such as those we have detailed as belonging to the case of Stafford; and moreover, I have a firm persuasion, that if ever the shoulder-joints of Stafford come to be anatomically examined, they will be found to bear a remarkable similarity in all their alterations to those which the preparation on the table shows, and which have been so faithfully delineated by Conolly in the engraving already alluded to (Atlas, Plate 2).

The preparation from which this drawing is taken is preserved in the Museum of the College of Surgeons. The history of the case is unknown, and but little reference is made to it in the catalogue in which it is designated merely as "a chronic disease of the shoulder." The appearances, however, cannot be misinterpreted by any one who has studied anatomically the effects of chronic rheumatic arthritis on the articular textures of the shoulder. If we look to the bones composing the affected joint we find them bearing everywhere the stamp of this disease, not only in the eburnation of their articular surfaces, whose margins were studded round with bony growths; but we find also the clavicle and acromion bearing characteristic marks which, we do not hesitate to say, have never yet been noticed as the result of any other disease. Passing from the consideration of the bones in this specimen to that of the other structures, we find that the capsule was thickened and distended with a large quantity of synovial fluid; that, in short, here the "hydrops-articuli" existed, which we have usually seen in other joints affected with chronic rheumatic arthritis (see Treatise, Plate ix., Fig. 1, A B). And that this was the disease which, no doubt, had affected this shoulder-joint, we may further infer from the circumstances,

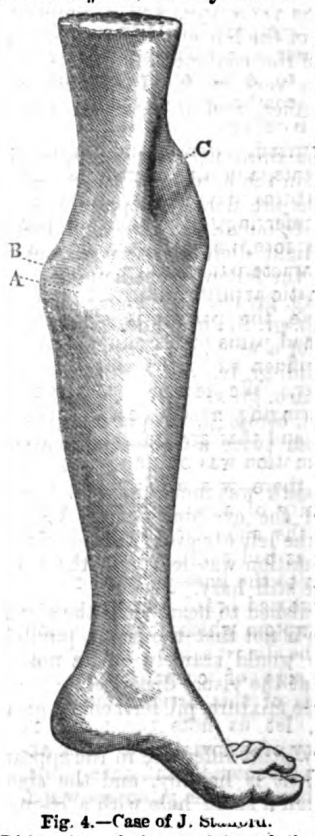

Fig. 4.—Case of J. Stafford. Dislocation of the condyles of the femur, B A, downwards and backwards to the popliteal space, and of the patella, C, with the bones of the leg upwards and forwards in front of femur.

that the glenoid ligament and the cartilage of incrustation, as well as the articular portion of the tendon of the biceps, all were removed; while, at the same time, there was a development of these "subovate bodies like melon seeds," which I have reason to believe should be classed among the morbid results exclusively belonging to chronic rheumatic arthritis (see Treatise, pages 199 to 206).

The *left knee-joint* presents now much more deformity than it did when the last account of it was given. The effusion of synovial fluid has been absorbed, permitting the prominency of the bones and tendons around the articulation to be more conspicuously seen than formerly.

This *left* lower extremity is now seen to be about two inches shorter than the right. This is the necessary result of the dislocation of the bones of the knee, and ascent of the bones of the leg in front of the femur, a lesion which is now very evident. Indeed, the ordinary signs of the dislocation of the lower extremity

of the femur backwards and downwards, while the bones of the leg and patella are drawn forwards and upwards in front of the femur, exist in the case under consideration, just as they do in the case of accidental luxation of the bones at the knee-joint, when the femur passes downwards and backwards, and the bones of the leg ascend.

In the case of accidental violence, all the ligaments, inside as well as outside the knee-joint, and some of the tendons, are suddenly ruptured, and the powerful muscles around forcibly shorten the whole limb, causing the bones of the leg in the luxation specified (and which existed here) to over-lap the lower extremity of the femur, and ascend in front of it, rendering the limb, as mentioned above, two inches shorter than the other limb.

In the case of slow chronic disease, the fibrous structures instead of being suddenly torn by violence, as above-mentioned, are slowly disintegrated by chronic disease, unaccompanied by suppuration, and when all the fibres of the ligaments are destroyed, then suddenly the surrounding muscles complete the luxation, as in the case of accident.

In the case of luxation thus produced as the effect of slow disease, we have the same shortening of the whole extremity, the same conspicuous rounded projections posteriorly into the popliteal space (see Fig. 4, A B), formed by the lower extremity of the dislocated femur, and anteriorly we have the same remarkable transverse sulcus in front of the femur, just above the patella, as we have in the accidental luxation. We can also remark in this case of Stafford the same resistance of the limb to flexion at the knee-joint; and we notice in cases of accidental luxation the same remarkable abnormal mobility in the lateral direction (see Fig. 3, page 519).

Fig. 5.—Case of J. Stafford. Dislocation at the knee the same as Fig 4; great lateral mobility.

With respect to the actual condition of the bones which enter into the composition of the knee-joint, they can in this case of J. Stafford be each respectively felt and moved, and their abnormal positions relatively to each other can be as easily comprehended as if they were bare before us; the states of the crucial, lateral, and capsular ligaments, and all the other articular textures may be easily inferred.

On referring to the clinical report of the foregoing case, we find all the characteristic features of chronic rheumatic arthritis alluded to. For example, the patient is stated to have had pains in his joints, which were influenced by the state of the weather. We learned that there were cringing noises heard in the joints, and that crepitation was felt when motion was communicated to them, there was also symmetrical deformity of almost all the joints. As to the shoulder, the right was nearly as badly affected as the left; and, as to the knee-joint, there was the increased breadth of the patella—a symptom which, in my opinion, might be almost said to be a pathognomic sign of chronic rheumatic arthritis of this articulation; and, finally, let us note the increased quantity of synovial fluid which existed in the shoulder and knee-joints, as well as the foreign bodies which could be plainly felt in both articulations.

All these point out sufficiently the case of J. Stafford to be a very remarkable one of chronic rheumatic arthritis, with abnormal mobility of the right and left shoulder, and of the left knee, amounting to complete dislocation of these three large joints in the same individual.

This is not the only case of abnormal mobility of the knee-joint I have met with, as a result of chronic rheumatic arthritis. I had under my care, in the Richmond Hospital, many years ago, a man named John Lynch (see Treatise, p. 301). In the report of the case, I observed, "that it is plain, from the history of the chronic affections of the right knee-joint of Lynch, the passive synovial swelling (hydrops articuli) by which it commenced, the stiffness and uneasiness influenced by the state of the weather, the 'cringing noises' heard on motion, &c., that this articulation presented to us an ordinary example of chronic rheumatic arthritis of the left knee, and with abnormal mobility of the articulation. It became necessary to support the weakened joint with knee-caps and by the methodical application of leather splints; but although the patient derived some advantage from these appliances, yet when he was discharged from the hospital as well as it was practicable to make him, he found himself incapable of earning his livelihood as a labourer, and was, therefore, compelled to seek an asylum in the North Union Poor-house, where he lived for four years only—his knee-joint underwent but little change, but he became affected with bladder disease, of which he died in 1842. The history of the case, and the post-mortem specimens, were laid by me before the Pathological Society of Dublin. On making the post-mortem examination, it is noted that as to the left knee, "This joint, now, as during the lifetime of the patient, presented great abnormal mobility in all directions, as if the articular surfaces had been merely held together by the integuments and tendons of the muscles. The capsular ligament was thickened, and contained but little synovia; the cartilage of incrustation had been partly removed; the lateral ligaments were elongated, and the *crucial ligaments* had lost all attachment to the tibia.

The lengthened condition of the lateral ligaments, and the unusual depth of the excavation of the internal condyle of the tibia, must have contributed somewhat to the abnormal mobility of the knee-joint noticed, but this condition, which had been so much complained of by the patient, was, I believe, principally due to the loss of the tibial attachment of the crucial ligament.

In another case I can refer to briefly here—viz., that of Mary Sheridan, æt. 56, a patient in the Richmond Hospital, Nov. 1, 1852—we find noted, that she laboured under chronic rheumatic arthritis in both her knee-joints, with great abnormal mobility. That as to her *left* knee it was remarked that the femur projected very much forwards and inwards, while the corresponding head of the tibia was partially displaced outwards and backwards towards the popliteal space, where it could be plainly felt. The leg and foot were rotated outwards, and the patella, at this side, was dislocated completely outwards, and lay on the external surface of the outer condyle of the femur.

When the limb was grasped above the ankle, and at the same time that a lateral movement of abduction was communicated to the leg, it could be made to form an abtuse angle nearly approaching a right angle with the thigh, and these movements were the source of no pain to the patient.

On examining the joint deeply, a number of foreign bodies could be felt under the fingers; on moving the joint crepitation was perceived, and loud crackling noises were distinctly audible.

We learned that in almost every particular that this chronic disease affected both the knee-joints of the patient on nearly a similar manner. She found both equally movable when she attempted to stand or walk, which she was unable to do without the aid not only of crutches, but she required also some one to support her.

She died on the 8th of November, on the 14th day after an acute attack of arthritis had supervened on the chronic affection of the right knee. On making the post-mortem examination, the capsular ligament of the right knee-joint presented a cut edge of three lines in thickness. To the

interior surface of the synovial membrane were attached patches of lymph, and traces of recent inflammation. The articular surface of the external condyle of the femur which corresponded to the external glenoid cavity of the tibia was completely polished and *eburnated*.

Left knee-joint.—The capsular ligament was of equal thickness with that of the right knee-joint; all the structures in the interior of the joint were observed to be in an hyperæmic state. The inter condyloid fossa of the femur was occupied with vascular synovial fimbriæ.

There were no traces whatever of crucial ligaments existing in the articulation—more than twenty foreign bodies were contained within its cavity. The patella was dislocated outwards, as before mentioned; it lay on the lateral aspect of the external condyle of the femur, presenting its inner margin forwards, its outer backwards, and its cutaneous surface external (see Fig. 6).

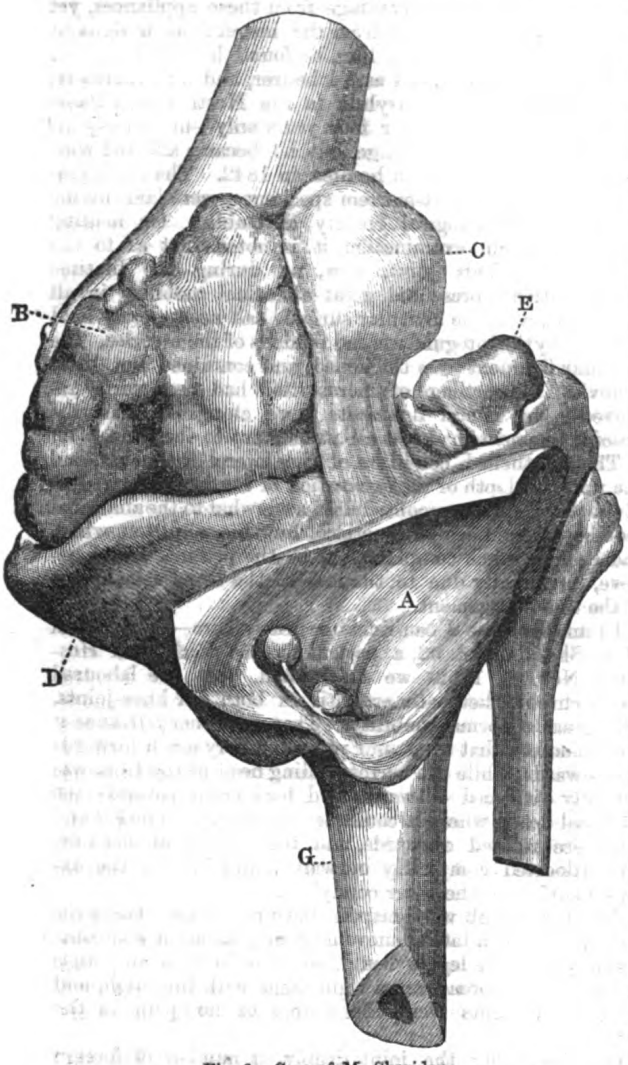

Fig. 6.—Case of M. Sheridan.
Left knee-joint. Patella, C, dislocated externally. Foreign bodies, E. B, bony nodules.

The abnormal mobility of the knees, which in this case was greater than ever I had seen it, was, I believe, principally owing to the loss from disease of the crucial ligaments.

From the foregoing considerations we are, I think, justified in arriving at the following conclusions:—

1. That besides the stiffness of the joints or articular rigidity of Cruveilhier as a symptom of chronic rheumatic arthritis, we sometimes meet with well-marked examples of this disease, in which quite an opposite symptom—namely, an *abnormal mobility* of the joints affected with this disease exists.

2. This abnormal mobility of joints noticed as an occasional result of chronic rheumatic arthritis, may amount to the degree of partial luxation only—or to that of complete luxation of the affected joints.

3. These dislocations of the bones, are attended with but little pain; even the inconvenience arising from them is inconsiderable, if only the joints of the upper extremity be affected; but, on the contrary, if the joints of the lower extremity, for example, the knees, then the inconvenience becomes so considerable, that the patient is unable to stand or walk, unless he has recourse to the use of such an appliance as that used for ten years in the remarkable case of J. Stafford (see Fig. 3, p. 519).

From observation of the foregoing and other examples of this disease, I have come to the same conclusions that Haygarth had done many years ago—namely, that "there is one painful and troublesome disease of the joints of a peculiar nature, and clearly distinguishable from all others, by symptoms manifestly different from gout, and from both acute and chronic rheumatism." This disease, "the nodosity of the joints," of Haygarth, I have ventured many years ago to call chronic rheumatic arthritis, and under such a denomination, I lay these cases this evening before the Surgical Society of Ireland.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

MISCELLANEOUS CASES FROM THE OUT-PATIENT PRACTICE.

Under the care of Mr. SPENCER WATSON.

Case 1.—FATTY TUMOUR IN THE SUBMAXILLARY REGION REMOVED BY OPERATION.

A WOMAN, aged 45 years, stout and healthy-looking, came up from Woolwich for the purpose of having advice respecting a tumour lying under the jaw on the left side. It was of the size of half an orange, soft, but not fluctuating, freely moveable on the subjacent parts, and quite unattached to the skin. When the skin was made tense by pressure behind the tumour, a characteristic lobulated surface was observed, which with the other symptoms made it evident that it was of a fatty nature. It having been decided that it should be removed, this was done on April 1st, 1863, by an incision of four inches parallel with the lower border of the left lower jaw. The tumour was encysted and easily separated from the surrounding tissues.

The wound healed rapidly, and with no trouble or difficulty whatever, leaving a very slight scar.

Case 2.—A FOREIGN BODY IMPACTED IN THE FLESHY PART OF THE CHEEK FOR NINE MONTHS.

W. H., a boy of 13 years of age was brought to Mr. Watson at King's College Hospital in the early part of 1864, with a punctured wound of the left cheek, the result of an injury several weeks before. The boy had been playing with another boy, who thrust at him with a wooden foil, the point of which entered his right cheek immediately in front of the masseter, and then broke off short.

A probe passed into the wound detected a somewhat hard substance lying about half an inch from the surface in a direction obliquely backwards.

A fine pair of forceps was passed down to this hard substance, but failed to seize it. After several explorations and ineffectual attempts to extract, it seemed most probable that the foreign body, if it had ever lodged in the wound, had subsequently escaped; and that the substance felt at the bottom of the wound was the exposed bone of the lower jaw.

At the same time this was rather doubtful, as the touch indicated a somewhat softer substance than the bone in this locality.

Nine months after the exploration of this wound, which

still remained open (December, 1864), the boy was again brought with a second opening in the cheek an inch and a-half behind the first, and a free discharge of pus from it. Sticking out of this second sinus was a hard substance, which, when seized and withdrawn, proved to be a piece of wood (deal) of a little over an inch long, with a sharp point at the end that was protruding, and a rough, jagged surface at the other. This was evidently the end of the wooden foil that had been broken off short in the wound at the time of the accident.

In about a week after the extraction of this foreign body the sinuses had almost entirely healed.

Remarks.—The direction taken by this pointed piece of wood was evidently under the massæter, and between it and the bone, and therefore quite close to, but across the course of the facial artery. It was so firmly wedged in that it was very difficult to ascertain any moveability in it by means of the probe, and considering the doubtful account of the accident, it did not seem worth while to make an enlarged opening. However, the event proved that this would have been the best practice, and that it would have saved the boy many months of annoyance and pain, besides the formation of a second opening and subsequent scar.

The case resembles in some particulars a case under the care of Mr. Bowman, at Moorfields Ophthalmic Hospital, in which the pointed extremity of a hoop-stick became imbedded in a boy's orbit. In this case there was an abscess formed, and the same difficulty was experienced in detecting the foreign body. Its escape was also similar, in being the result of pathological processes, rather than of surgical skill.

The firm impaction of the piece of wood between the muscle and the bone, rendering it immoveable, and so obscuring the diagnosis, is a noticeable feature of the case, and the shape and jagged surface of the thick end of it sufficiently account for the fact that it did not make its way out of the original wound. As we often see in the case of a broken needle imbedded in muscles, it made its way to the surface with the pointed extremity forward, *i.e.*, in the direction in which its progress met with least resistance from the surrounding tissues.

Case 3.—PARTIAL DESTRUCTION OF THE PREPUCE FROM THE RAPID GROWTH OF WARTS, COMPLICATED WITH PHYMOSIS.

A man, æt. 20 years, came to the hospital on March 23rd, 1864, with the following condition:—

The glans penis was surrounded by a luxuriant crop of fleshy warts and surrounded by an œdematous and shining mass of mucous tissue, which, on close inspection, proved to be the inverted prepuce, partially amputated by a sloughing sore, but still adherent to the integument of the penis above.

It was evident that destructive inflammation, set up by the distension of the prepuce, had ended in sloughing, and the obvious treatment was to remove the redundant and useless piece of integument, and the warty growth.

This was done, and soon a healthy granulating surface was obtained.

In a very similar case that occurred to Mr. Watson, in February, 1865, the patient came with a threatening slough, and with warts protruding from the orifice of the prepuce.

He refused operation, and in the course of a fortnight sloughing took place, and the glans penis protruded through the opening in a manner similar to that of the case related above. The prepuce was slit up with great relief to the patient in this latter case.

These two cases show the importance of an early attention to the condition of phymosis. This condition may lead to various local mischiefs, and is probably, if not a cause, at any rate a promoter of warty growths in the sulcus between the glans penis and the preputial covering. If in these cases the phymosis had been remedied by an early operation, it is probable that the subsequent troubles might have been entirely avoided.

CITY OF DUBLIN HOSPITAL.

OPERATIONS PERFORMED ON THE 17TH JUNE.

By Mr. CROLY.

Case 1.—CASTRATION FOR TUBERCULAR DISEASE OF THE LEFT TESTIS.

M. C., aged 35 years, a labourer, resident in the Queen's County, was recommended to Mr. Croly for operation, and admitted into the hospital on the 13th inst.

History.—Three years ago the testicle became sore and swollen; it gradually increased in size to the present time; within the last ten days a small spot ulcerated on the front of the tumour; the patient suffers pain like the "sting of a nettle," and he also experiences a dragging feel in the region of the spermatic chord and loins. He says he never suffered from venereal disease.

Condition of patient and appearance of tumour on admission to hospital:—

His general health appears to be good. The left testis is about the size of a large orange; there are several large veins ramifying over its dependent part; the tumour is heavy; there is one small ulcerated spot on the anterior part, about the centre, and a prominent point which looks as if it would burst and form a similar ulcer; the spermatic chord feels thickened; there is no glandular enlargement observable; the right testis is of natural size.

The patient had been under surgical treatment for many months, but nothing seemed to take any effect on the size of the tumour.

Mr. Croly held a consultation with his surgical colleagues, who agreed with him as to the necessity for operative interference, in consequence of the testis being destroyed by the disease and the irritation which it continues to cause the patient, rendering him unfit to work.

The operation was accordingly performed as follows:—

The patient having been chloroformed and the hair removed, Mr. Croly grasped the testis behind and made an elliptical incision with a scalpel, commencing at the external abdominal ring and terminating at the lower part of the scrotum. A second elliptical incision of the same length was then made, which included the ulcerated part and prevented too much integument being left. The spermatic chord was carefully dissected out, and held with Ricord's forceps. The chord below the forceps was divided and the vessels tied separately; the lower part of the chord was then draw forwards and the testis dissected from the bottom of the scrotum to which it was firmly united by adhesions. In separating the organ from the septum the handle of the knife was used to avoid wounding the artery of the septum or the opposite testis. Several bleeding vessels in the scrotum were tied, the wound was left open to allow the surface to glaze, and the patient was carried to his bed.

Pieces of ice were placed in the wound, and the part left exposed to the air. In four hours, as all oozing had ceased, Mr. Croly removed some small clots of blood, and sponged the surface with carbolic acid and oil. He then brought the edges of the wound together with the interrupted iron wire sutures.

The section of the testis exhibited a well-marked example of the strumous disease.

Case 2.—REMOVAL OF AN EPULIS FROM THE SUPERIOR MAXILLA.

Mrs. C——, aged 34 years, residing in the county of Waterford, was recommended to Mr. Croly for operation.

History.—A year and a-half ago the disease commenced by a small blister inside the gum corresponding to the incisor teeth of the upper jaw. The growth increased gradually, and in six months the teeth were loosened by the tumour, and were finally extracted. She never suffered pain in the part, but the deformity caused her much annoyance.

Appearance of disease on admission into hospital:—A red,

hard tumour about the size of a small walnut is observed occupying the position of the four central teeth, it is not painful to the touch, nor does it bleed when manipulated. It extends upwards on the gum anteriorly, and bulges out the upper lip, and covers posteriorly the alveolar process, and approaches to the hard palate.

The operation was performed as follows:—The patient was fixed in a chair, her head resting against the breast of an assistant. Mr. Croly commenced by making an incision with a stout scalpel through the gum at each side of the tumour, and having inserted the blade of a fine saw, next divided the alveolar process through each wound, he then with a stout cutting pliers removed the "epulis," including a portion of the alveolar process. The operation was performed with rapidity, and there was very little hæmorrhage. The patient was directed to keep pieces of ice constantly in her mouth.

We learned on inquiry that these cases have progressed very favourably since operation.

RICHMOND SURGICAL HOSPITAL.

Cases under the care of Mr. WILLIAM STOKES.

(Reported by Mr. JAMES ROSS.)

STRUMOUS DISEASE OF THE ANKLE-JOINT, OF TWO YEARS' DURATION: SYME'S AMPUTATION AT THE ANKLE-JOINT: RECOVERY.

AMPUTATION at the ankle-joint, as first suggested and practised by Professor Syme, has long and justly been considered one of the greatest modern improvements in practical operative surgery. The following case adds another to the long list of those which have shown so unquestionably the great importance of this procedure, and there are the particulars of it will, it is hoped, prove of some interest to those earnestly engaged in the advance of surgical art.

Bridget C., æt. 23, a native of the South of Ireland, was admitted into the Richmond Hospital on the 27th of last March, having been recommended to Mr. Stokes by Dr. Lyons. The patient is of a delicate strumous temperament, and from long-continued suffering and many sleepless nights, had the careworn and anxious expression of face seen so invariably in those who are the subjects of protracted and painful disease. The patient states that about two years ago, without any assignable cause, the joint became affected. She does not remember ever having got any blow on or near the joint, nor does she remember ever having even sprained the ankle. About twelve months after the joint first became affected, the pain and swelling in it became so aggravated as to render walking or standing no longer possible. She was then recommended by her friends to consult a so-called "bone-setter" of considerable local celebrity, who informed her that in his opinion the bones of the ankle-joint were displaced, and that an attempt should be made at once to restore them to their natural situation. Accordingly the joint was subjected to what, from the description, must have been very violent extension and twisting, in order to effect the reduction of the supposed luxation. After this violent, and, in truth, atrocious treatment, the previously existing symptoms became much aggravated, the pain especially, which never allowed her a single night's rest. Any attempt to walk or use the joint was now wholly out of the question. Things remained in this way for several months, and then, as the symptoms were evidently not diminishing in intensity, she determined to seek for surgical advice in Dublin.

On examination, the enlargement, which was very considerable, was found principally over the astragalus. There was exquisite tenderness over the joint, especially over its inner side. The slightest motion of the joint gave extreme pain. At night she suffered much from shooting and stinging pains, which gave her much distress. There were no sinuses, or any evidence of abscess-formations. The anterior portion of the foot was healthy. There were no hectical symptoms, cough, or diarrhœa, and her appetite was good. Looking at the history of the case, the urgency of the symptoms, and the length of time they had lasted, it was clear the case was one demanding prompt operative interference, and one of two procedures was contemplated by Mr. Stokes—namely, either resection of the ankle-joint, or amputation, in the manner first recommended and practised by Professor Syme. Looking, however, at the debilitated condition of the patient, and the strong probability of the disease not being sufficiently localised in any particular part of the tarsus—circumstances which would militate strongly against a successful resection of the joint, amputation was deemed preferable, and accordingly determined on. The operation was accordingly proposed to the patient, who willingly acceded to it.

On the 2nd of April the operation was performed precisely as recommended by Professor Syme. Mr. Stokes was anxious, in arresting the hæmorrhage in this case, to give the method of torsion a fair trial, but the result was not at all as satisfactory as he would have desired. Very considerable difficulty was experienced, especially in arresting the hæmorrhage from an interoseous artery, which, however, had eventually to be secured by a ligature. After the operation the wound was simply dressed with dry sharpie. On examination of the foot, the disease was found to be more extensive than, from the previous symptoms and appearances, was at all anticipated. All the bones of the tarsus were more or less diseased, the morbid process, however, being specially evident in the astragalus, the greater portion of which was completely softened and diseased. A very remarkable condition was found on the articular surface of the tibia, namely, an adventitious ridge or bony prominence, which extended horizontally across the centre of the articular portion of the bone, and which seemed to have become developed in order to replace the body of the astragalus, which, from disease, had become softened and flattened. The cartilage of incrustation on the articular surfaces of the tibia and astragalus were eroded and ulcerated, but the carious process in both the tibia and fibula appeared to be extremely limited, and when the section of these bones was made, the oseous structure appeared perfectly normal.

In some clinical observations to the class of the hospital, suggested by this case, Mr. Stokes could not avoid congratulating himself that amputation, and not resection, had been resorted to in this case; and remarked that notwithstanding the arguments so ably and forcibly put by Mr. Hancock, the distinguished Surgeon of Charing-cross Hospital, in favour of resection in cases of caries of the ankle-joint, he, Mr. Stokes, could not avoid coming to the conclusion, that although, doubtless, the operation of resection was indicated before all others in many cases of injuries of the ankle, such as, for example, gun-shot injuries, as shewn by the remarkable results obtained by Professor Langenbeck during the Schleswig-Holstein war of 1864, and in many cases of disease obviously originating from injury; yet that, in caries of the ankle-joint, in the ordinary acceptation of the term, the morbid process is seldom, if ever, so localized as to justify resection; and in such cases, therefore, amputation at the ankle-joint is in every way the most satisfactory, and most scientific, operative procedure that can be had recourse to.

It would be tedious, as well as unnecessary, to give the daily progress of this case. On May 2, exactly one month after the operation, it is noticed in the case-book that "during past week case has progressed without a bad symptom. Wound is nearly healed. Promises to be a most successful result." A fortnight after this date the wound had completely healed. The patient's health has in every way signally improved. She has gained flesh, eats, drinks, and sleeps well, and is cheerful and happy. Every fine day she goes out in a basket carriage, and is driven about in the grounds of the hospital.

LORD OVERSTONE has accepted the office of President of Charing-cross Hospital, rendered vacant by the death of the late Marquis of Salisbury.

WEDNESDAY, JUNE 24, 1868.

THE MEDICAL CANDIDATE FOR EDINBURGH AND ST. ANDREWS.

DURING the last week most of the leading journals have announced that Dr. PROSSER JAMES has accepted an invitation which has been presented to him to come forward as a candidate for the representation of these Universities in the new House of Commons. We are able to inform our readers that the requisition was presented some months ago, and that Dr. PROSSER JAMES has the support not only of some of the most eminent members of our profession, but also the confidence of a large section of the liberal party, and the cordial good-will of influential statesmen.

The *Scotsman* of the 13th announced the candidature in the following terms :—

"A requisition, signed by professional and other gentlemen, has been presented to Dr. Prosser James, of the London Hospital. Besides the ordinary committee for promoting the election of Dr. Prosser James, a Medical Committee has been formed, consisting of members of the profession who desire to see the medical element in the House of Commons increased, and who consider Dr. Prosser James a suitable candidate."

The *Observer* of the 14th spoke of his chances as "most favourable." The *Daily News* and several other papers informed their readers that he was a "staunch liberal in medical as well as in general politics." The *Times* and some other papers merely announced the acceptance of the invitation. The *Star*, after the announcement, proceeded to comment as follows :—

"Dr. James properly recognises the fact that the requisitionists look to him as a medical politician to represent the practical interests of the profession, because he has for many years both by pen and tongue been an active advocate for reforms in his profession. Ten years ago he presented his plans and vindicated his policy before Lord Palmerston, and almost stood alone in opposing the proposition that the Medical Council should consist of delegates from the existing corporations, because, as he very properly alleged, such a system would not secure representation to the profession at large, but would perpetuate the existing abuses. Dr. James advocates that the members and graduates of each licensing body should elect their representative to the Medical Council ; he is in favour of a radical reform of the Poor-law medical system. In general politics Dr. James is broadly Liberal ; opposed to religious endowments and religious tests. A number of eminent gentlemen have already pledged themselves to support Dr. James's candidature."

In order to furnish our readers with the fullest particulars, we append the requisition and the reply :—

REQUISITION TO

PROSSER JAMES, ESQ., M.D.,

PROFESSOR OF MEDICAL JURISPRUDENCE AT THE LONDON HOSPITAL, &C., &C.

SIR,—It seems to us highly desirable that several medical men should obtain seats in the new Parliament, and that it is particularly fitting that University Constituencies which contain so large a proportion of medical electors should be thus represented.

The great interest you have for many years evinced in political matters, especially in those great social questions in which medical men are particularly qualified to reason ; the intense desire you have shown to elevate the profession of medicine and secure its members their just rights and influence, and the considerable sacrifice you have made to forward these objects ; the active part you have taken for so many years in the general as well as in the medical press, in which you have consistently advocated the most liberal principles ; the time you have devoted to the study of jurisprudence as a whole, as well as to the medical branch which you teach at the London Hospital. and which includes all the great questions of hygiene and state medicine, point you out in our opinion as eminently qualified to represent the medical profession in Parliament.

Besides this, as a gentleman in actual practice residing in London throughout the year, and still employing your leisure hours in promoting objects of general usefulness, you must be conversant with a variety of topics of the highest political importance, as well as with the wants of your professional brethren, and the actual state of opinion amongst their several ranks, and well qualified to serve them.

We are convinced also that in you the cause of the general Practitioner. and of the Poor-law Medical Officer, would have a warm friend and advocate, while medical and sanitary reform in general would have a suitable representative.

We therefore beg most respectfully to request that you will allow yourself to be put in nomination as a candidate in the liberal interest for the honour of representing the two ancient Universities of Edinburgh and St. Andrews, and to assure you that it will afford us great pleasure to use every effort to secure your return.—We have the honour to be, Sir, &c.

[REPLY.]

GENTLEMEN,—In responding to the requisition you have done me the honour to make, of allowing myself to be nominated as a candidate for the honour of representing the Universities of Edinburgh and St. Andrews in Parliament, I cannot conceal from myself the fact, that it is as a representative of the medical profession that you invite me to come forward, and that you are influenced to do so by the attention I have for many years bestowed on questions influencing the position of that profession, rather than to those legal and literary studies to which you allude as additional qualifications for the position you are pleased to consider me worthy to attain.

This being so, I cannot do better than commence my statement—and I presume you look for some statement of principles in reply to your invitation—by reference to professional politics.

More than ten years ago, I had the honour of laying before the late Lord Palmerston, then first minister of the Crown, my views as to the subject of medical reform, my objections to some of the plans proposed, and the outline of a scheme for preparing a measure beneficial and satisfactory alike to the profession and the public. Since then, the General Medical Council has come into existence, but I think it would be well to look back to that scheme as a commencement of this review.

It will be remembered that in the bill brought forward by Mr. Headlam, it was proposed to entrust the government of the profession to a new council, to be composed of a delegate from each of the existing corporations. This idea was accepted by many admirers of the representative system, but I urged that such a body would represent, instead of the medical profession, the conflicting interests of the rival corporations, and as such would be likely to become the arena of unseemly contention. Fully alive to this, Lord Elcho proposed to place the nomination of the members of the council entirely in the hands of the Crown advisers. To this I objected that such a board, although it might prove a good working committee, could scarcely hope to gain the confidence of the profession, while it would inevitably excite the jealousy of all the corporations.

Adopting most heartily the principle of representation, the

scheme I submitted to Lord Palmerston was neither more nor less than an adaptation of the representative plan to existing institutions.

My proposal was that the appointment of the members of the Medical Council should be confided—not to the governing officials of the corporations, but to the members of the profession connected with them ; in fact, that the representative of each body should be elected by those who held its medical diploma, the votes being given by signature. Thus the Members of the Colleges of Physicians or Surgeons, would have elected the representatives of those bodies, while the medical graduates of the Universities would have exercised the franchise of those institutions. A Council thus elected would have fairly represented the bulk of the profession, and would, I believe, have been more beneficial to the public than the one that was actually created.

The existing Council is the result of a compromise. It consists of deputies from the small governing bodies of the corporations, with an infusion of nominees of the Crown. Already a cry for its reform has been raised. An agitation for the representation of the working practitioner in the Council which rules and taxes him has been commenced. The demand is so reasonable and just, that I have not hesitated to give it such influence as I possess—believing it may prove a good starting point ; but I am thoroughly convinced that the scheme I sketched so long ago would have been far the best, and, I think, medical reformers should even now endeavour to bring it into operation.

Thus the true plan of medical reform, in my opinion, is to insist on an extension of the franchise in the election of members of the Medical Council—our Medical Parliament. For example, instead of allowing the ruling bodies of the Colleges of Physicians and Surgeons to nominate the Members of Council, the members of these Colleges should put forth their claims for a voice in the election of their representatives. So with the Universities ; the Medical Graduates should insist on similar rights.

In this way too several battles may be waged at once. The members of the several corporations should put forth their claims simultaneously. It is scarcely to be believed that in the present day all the ruling committees will refuse to listen to so just a claim, and as soon as one body shall have accomplished so necessary a reform, it will be but a question of time for the others. The Medical Council will soon become what it ought to be, a representative Parliament of the Medical Profession, and before it will be a career to which, as it now exists, it can never aspire.

And now, with regard to the duties of a Reformed Council. In my first plan I laid it down as an axiom that what has been called the "one portal" system should be adopted—that every practitioner should enter the profession by a *minimum* examination. The only reason for the State interfering with professional qualifications, is to provide an adequate supply of practitioners, to whose care the people may safely entrust themselves.

The State should give to qualified persons a license to practice every department of the profession. The Corporations and Universities could confer their distinctions on those legally authorized practitioners who sought them. To carry out the plan I proposed that three joint boards of the existing examining bodies of the three kingdoms respectively, should hold the examinations for the State license, and I held that it should be insisted on, that no medical degree or diploma should be conferred by any University or Corporation on any person who had not been duly authorized to practice all branches of the art of healing, by one of these joint boards.

The experiment of the Medical Council has proved that this plan may be still further simplified. In place of three coordinate boards for the three kingdoms, one only would suffice, and when the existing Council shall have been reformed in the manner I have pointed out, there will be no reason why it should not undertake the examinations for the State License. It is proved that the Council can meet in London as a whole. It would be as easy to meet alternately in Edinburgh and Dublin, and thus save Scotch and Irish candidates the necessity of travelling to London. Under such a system the general practitioners of the country would have uniform education, pass through similar examinations, and possess the same privileges ; the State would do all that could fairly be expected from it, and the Colleges and Universities would not be effaced, nor have their rights much restricted, as they would only be deprived of the power to grant licenses to compete with that of the State.

Then would begin the day of competition upwards. The diploma of each body would be esteemed at its true worth, and sought accordingly. The corporations might, therefore, be left to make their own regulations—the first only being required to be that every candidate had previously obtained the State License. Membership of a College would then be sought as conferring particular privileges, leading to particular offices in the College, or proving the possession of special knowledge. So with University degrees.

Some higher diplomas would possibly imply superior general education. Not unlikely, candidates for the fellowship of colleges or the doctorship in medicine would be required to possess a degree in arts; but all such regulations could safely be left to the corporations concerned.

Such is an outline of my present views respecting the constitution and duties of the Medical Council. They are the natural outgrowth of the plan I was the first to put forward and have for a long time advocated.

You rightly calculate on my warmest sympathy with the general practitioner and the overworked but ill-paid Poor-law medical officer. These last I wish to see adequately remunerated for their arduous duties, and I am inclined to think they should be so paid, as servants of the State, that they might be required to renounce all private practice, and devote their whole time to the poor. The State would thus secure able and willing servants to spend their lives in its service.

Inspection might then easily be carried out by skilled medical inspectors, acting much in the same way as the Lunacy Commissioners now do in another department. We might thus hope to see our Poor-law system redeemed from some of its worst vices.

I must not forget, however, that your invitation implies more than the confidence of my professional brethren. Such a constituency as that of two universities must be deeply interested in all educational and social questions, as well as those of general politics.

Let me add, then, that my medical politics are but a portion of the broadly-liberal principles which I hold in relation to all other questions.

Education I should be glad to foster and promote throughout the land. Like others, I have been much struck with the necessity for extending primary education, though I cannot profess myself so staggered by recent revelations, nor so mistrustful of the men to whom the franchise has been extended, as to be ready to call in the policeman to force the children of unwilling parents to school. The plan of examining children at a certain age, to see if they can read and write, seems to me at least to savour more of the spirit and love of freedom.

Sanitary questions, like all others relating to State medicine, form, as you justly observe, a part of the subject I have the honour to teach at the London Hospital, and are therefore not likely to be forgotten by me.

I should gladly see all religious tests removed from candidates for university honours. I have always regarded the establishment of the church of the minority in Ireland as an injustice. A religion unable to maintain itself I do not believe in, nor do I think those religionists very earnest who are unwilling to support the faith they profess. From this point of view the Irish Church seems to me as indefensible as the more paltry, but still irritating exaction of church-rates in England.

If asked to what purpose I would apply the church revenues, I reply that such funds are national property, and as such Parliament has a right to dispose of them as seems best for the interests of the State. In the case of the Irish Church property, I think it should be restricted to the benefit of Ireland, and perhaps its most natural use would be in the promotion of education.

Questions respecting parliamentary reform may be considered set at rest for a time, until we see the working of the Reform Acts, but I may say that I am by no means inclined to look upon those acts as closing all discussion with the exploded formula "finality."

Without adopting all the opinions of anyone, and asking, therefore, to be permitted to consider all questions as an unpledged, independent Liberal, I am happy to accede to your request to come forward as a *medical* candidate for the honour of representing you in Parliament.

With the greatest respect, and many thanks for the confidence you have shown me, I am, gentlemen, your faithful servant,

PROSSER JAMES.

18, Dover-street, Piccadilly,
June 1, 1868.

THE REPRESENTATION OF THE SCOTTISH UNIVERSITIES.

More than a year ago, in a special supplement to The Medical Press and Circular, we discussed the subject of university representation in reference to the Medical Profession, and the prospect of the Scotch Universities returning a medical candidate to the House of Commons. We have also, before and since, again and again, expressed our earnest desire to see the medical element in Parliament increased. We happen to know that our views on this point are shared, not only by the bulk of the Profession, but by a large number of politicians, and by more than one of the leading statesmen of the time.

We are therefore glad to see that the opportunity will be afforded to some of the constituencies to elect a medical representative. We mentioned a year ago that medical graduates would be likely to come forward, and Dr. Prosser James has at length declared himself ready to contest the seat bestowed on Edinburgh and St. Andrews, as will be seen in our present issue.

For Glasgow and Aberdeen we were the first to indicate Dr. Andrew Clark as a suitable candidate, and now our medical contemporaries are endorsing our views; and although it may be premature to say positively that he will meet the advances, we believe that the medical graduates have only to express a decisive wish, and he will respond.

We may repeat, in reference to this, that Dr. Andrew Clark is well-known in political as well as in medical circles, and has always exhibited a deep interest in those questions which the Profession desires to bring before Parliament. He is a graduate of Aberdeen, and would unite local with medical influence. He is an active, scientific worker in his profession, a fluent speaker, and otherwise well qualified to serve his brethren. We hope the medical graduates will exert themselves to bring him forward.

REPRESENTATION OF THE QUEEN'S UNIVERSITY IN IRELAND.

The Graduates of the Queen's University have been actively pressing on the Government their claims to Parliamentary representation under the New Reform Act, but, as the redistribution of seats under the Irish Bill has been postponed to the new Parliament, their claim has been, of course, adjourned with it. In anticipation of the possibility of their success an influential deputation headed by the Bishop of Killaloe was received by Mr. Disraeli last week, and laid their case before him. The medical section of the Graduates was represented by Dr. J. S. Hughes, Professor of Surgery and Dr. Mapother, of Anatomy and Physiology in the Royal College of Surgeons in Ireland, Dr. Roe, and others. Notwithstanding the withdrawal of the redistribution scheme two efforts were made in the House of Commons on Thursday last to carry the object. Mr. Chichester Fortescue moved a clause to the effect that the two members now returned by Trinity College should in future be returned by the joint constituencies of that and the Queen's University, basing his argument on the fact that the constituency of the University of Dublin was relatively much smaller than that of Oxford or Cambridge:—

"By a Parliamentary return it appeared that the constituency of the University of Oxford consisted of 4190 voters, being one member to 2095 electors. The University of Cambridge consisted of 5440, being one member to 2720 voters. The University of Dublin consisted of only 1870 electors, or one member to 935 voters. This was within nine of the number of the voters of Dublin University in 1834, when two members, instead of one, were given to the University. In the London University in 1866, the number of graduates of Convocation standing was 1700. Neither of the Irish Universities could be said in the main to be, like those of Oxford and Cambridge, Universities on the collegiate footing. The Queen's Colleges were not, in the Oxford sense, colleges for residence. The total number of undergraduates in the University of Dublin in the year 1851-2 was 1217. Of these only 118 resided in the college; 581 more lived in Dublin and its suburbs, and the remainder, 518, attended lectures elsewhere. Thus, the University of Dublin, as far as it performed the functions of a collegiate University like Oxford and Cambridge, provided for the discipline and residence of only 118 of its undergraduates, while with respect to 518 it was on the footing of the Queen's Colleges or the Scotch Universities; and in regard to 581, it was upon the footing of London University, giving degrees solely on the passing of a certain stated examination, and not requiring either attendance at lectures or residence in college."

The Earl of Mayo in opposing the motion pointed out that—

"The amendment proposed to join for the purposes of representation two bodies that were essentially distinct, and which had different opinions upon almost every subject; and the combination of them could produce nothing but discord. The strongest objection to the proposal was that it was strongly objected to by both the bodies concerned. He had always entertained the opinion that if it were possible it would be desirable to give Parliamentary representation to the Queen's University, and he would have proposed to give it in the redistribution scheme which had been submitted to the House but for the pressing claims of the large populations. In any future scheme the claims of the Queen's University must be considered. It would now give a constituency of 880, but in a few years it was expected the increase of members would give a large, independent constituency. The present arrangements with regard to the qualifications for voters for the Dublin University were not altogether satisfactory. The voter must be an M.A., and pay £5 for registration and £9, 10s. on taking the degree, so that it cost £15 to become a voter of the University. Hence the disparity between the roll of Masters and that of electors, the latter containing 1870 names, and the former 1496 additional. He was empowered by the authorities of the University to say he should be prepared, when the Registration Bill was before the House, to make an alteration in the system which had hitherto prevailed at Dublin. He would propose a clause to give the franchise to every M.A. on taking his degree, without requiring as a condition the payment of any fee."

Mr. Gregory energetically supported the proposal, and accused Trinity College of returning as its representatives gentlemen—

"One of whom was a steady opponent of every measure which had for its object civil and religious liberty ("No!"); and *the other was the law adviser of a Tory Government—the fourth in succession.* They were all honourable men; but if the University of Dublin rested its claims to representation upon the fact that it always sent here a mouth-piece of the Irish Church and a law officer of a Tory Government, the sooner that confederation was broken up the better."

By a majority of 10 in a house of 356 the proposal was rejected. At a later period of the evening, Mr. Fawcett proposed a clause to disfranchise Portarlington, and give the seat to the Queen's University, but the suggestion was opposed by the Chief Secretary on the ground that it

should form part of the scheme for the redistribution of seats which has been postponed until the new Parliament. Mr. FAWCETT, however, in spite of the advice of several hon. members refused to withdraw his motion, and was defeated by a large majority.

Lord MAYO's objection to the proposal for the fusion of the representation of the two Universities appears to us to be sensible and well-grounded. The interests to be represented in each are as unconnected as the objects and feelings of rivals can be, and Mr. FORTESCUE failed to show either the necessity for diluting the constituency of Trinity College, or the justice of putting off the graduates of the Queen's University with the moiety of two members who could never accurately represent the views of either constituency.

NOTES ON THE ABYSSINIANS.

No. II.

THE ceremonial observed at Births among this ancient people, we give on the authority of Mr. Mansfield Parkyns.

At the time of parturition the woman is seated nearly upright on two stones, slightly separated from each other. She is supported by a female friend, who holds her shoulders, and constantly invokes the aid of the Blessed Virgin.

The feet of the patient are supported on a chair or table, and are there held by another female attendant who, from time to time, rubs her feet and the calves of her legs which form an angle of about eighty degrees with her body. As soon as the shoulders of the child appear, the delivery is assisted by the women, who receive the infant into a flat wicker basket filled with flour. The child is forthwith washed in cold water and perfumed, and a woman then moulds the head and the different features by pressing them with her fingers, in order to make them handsome; while a man pokes a lance into the infant's mouth—if a male—to make him courageous. This he does through the window, for no man would enter the chamber, which is socially and religiously regarded as unclean. Simultaneously with this performance a little boy cuts the throat of a fowl before the newly born babe, and the women shout with exultation, repeating the cry thrice if the infant be a female, and twelve times in the case of a male. This done, they rush into the court which surrounds the house "singing and dancing like so many bacchanals; and woe betide the man who is unlucky enough to be caught by them; for they surround him, and by their yelling, singing, dancing, and screaming, literaly stupify him; nor do they let him go till he has promised them a ransom, either of beer or money, or some other kind of present."

Three days after the birth the women go through a similar ceremony on the occasion of carrying the mother's clothes to a brook to be washed; every male friend then captured on the road is treated as just described. The women all feed on porridge, which has been the mother's food since the day of her delivery, and the flour of which she had previously prepared with her own hands. The child is usually suckled by any woman who may happen to have milk, until the mother can take it herself; and butter, and sometimes honey and milk, are stuffed into its mouth. The curious combination of Circumcision and Baptism is thus described in chapter xxix:—

"After eight days the child is circumcised, be it male or female, and on the tenth day, if it be a boy, or on the twentieth day, if a girl, the priests come with all the pomp and ceremony of the Church—crosses, incense, &c., and purify the house, sprinkling it with holy water. On the day of the child's birth the priest makes his calculation as to when it is to be baptized, informing the father (who probably cannot read, or, if he can, does not perhaps possess an almanac) of the particular day on which the ceremony must take place—forty days after the birth of a boy, and eighty after that of a girl. On inquiring why so long a time is allowed to elapse, and whether it might not be curtailed in case of sickness, I was informed that it might be shortened if absolutely necessary, and that the reason of the delay in ordinary cases is, that according to their traditions our first parents did not receive the Holy Spirit until they had been created that time respectively. The Abyssinians are, however, very particular that the exact day should be kept; so much so, that if the father miscalculates the day and is not forthcoming, he is subjected to a heavy penance. The priest would probably order him a year's fasting; but a trifling sum as a present to the Church (which means in fact a present to the priest) would readily induce him to commute the period to a month or two. It sometimes happens that the priest himself miscalculates, and assigns a wrong day; in which case he has to undergo the penance that he would have inflicted on the father.

"The parties having arrived at the Church, the priest receives the child from the godfather, places his hand on its head, and pours on it a little water. He then takes oil, and signs the cross on the child's head, hands, breast, and knees, and concludes by tying round its neck a plaited cord of red, blue, and white silk, as a sign of Christianity. (This cord is afterwards exchanged for the blue one usually worn.) The priest then returns the infant to its godfather, exhorting him to support and educate it, and look after its welfare, spiritual and temporal, as though it were his own child. This the sponsor promises to do; but pays no more attention to his promise than do our good godfathers and godmothers in England; only, should he die childless, his godson is considered the lawful heir to his property. After the conclusion of the ceremony the priest returns with the whole party to the father's house, where a great feast is prepared in honour of the occasion."

Marriages take place at a very early age, eight or nine in the case of girls, and boys when a little older. The ceremonies observed on these occasions are fashioned on the Oriental rather than on the Western model. They are, however, mostly civil marriages. Church marriages are rarely solemnized save between parties who, having been first civilly married, and having subsequently lived together happily till the decline of life, begin to feel that they could not suit themselves better, and so determine to consecrate the marriage by going to church and receiving the sacrament. In this event the bond is indissoluble; while the civil union may be dissolved on short notice, and for almost any reason. The parties concerned need only express a wish to separate, and a division of children and property takes place. The boys, if any, commonly go to the father, and the girls to the mother. This done, they are at liberty to contract a second marriage. "It is not an uncommon thing [writes Mr. Parkyns] for a man thus separated from his wife to maintain her in a house near his own, furnish her with the necessary means of subsistence for herself and family, and continue apparently in perfect friendship with her, but never approaching her as a husband, while at the same time he takes another bride in her place."

Notes on Current Topics.

The Medical Council.

THIS body meets to-day at the London College of Physicians, and many important questions will be discussed during its sittings. We shall, as usual, furnish our readers with an account of the proceedings of its ruling body, and we sincerely hope that those of its members who are ready to advocate an essential reform of its constitution, will not hesitate to push their views. It has become evident that a reform of its constitution is the one great question of medical reform on which all others depend, and no time can be better spent than in discussing the various schemes that have been proposed by medical politicians since its last meeting.

Royal College of Surgeons of England.

The coming election of councillors continues to produce an increasing excitement amongst the Fellows of this College, and we sincerely trust that a large number will record their votes in favour of progress. The names of the competitors have already appeared, and their merits been canvassed in our columns.

A special meeting of Council is called for the 25th, to elect an examiner in place of Mr. Lake. Either Mr. Lane, Mr. Busk, or Mr. Hancock are presumedly to be elected. The examinership in Dental is also to be settled the same day, and it is thought that this post will be conferred on Professor Partridge.

The Great Poor-Law Meeting in London.

The aggregate meeting of London and Provincial Poor-law Medical Officers comes off this afternoon at two o'clock at the Freemason's Tavern, under the Presidency of Mr. Clement, M.P., for Shrewsbury, a distinguished member of the Medico-Political Association. Our interest in our Poor-law Medical brethren is well-known, and has never yet been questioned. The medical students of London have been invited to attend, and are likely to give a hearty support to their friends. It is probable that several leading members of the Medico-Political Association may also be present.

The Jenner Banquet.

This great demonstration of respect was undoubtedly an unusual success. The mere report of the proceedings gives no idea of the feeling that prevailed, and we therefore the less regret that our space forbids an extended account of it. It is known to not a few that Sir William Jenner, besides his handwork in scientific medicine, has devoted much energy to the social and political questions which affect the profession, and exhibited interest in the state of the Poor-law system.

Had the graduates of the London University selected him as a medical candidate for Parliamentary honours, the mere politicians who aspire to represent that constituency, might have found many of those on whom they counted supporting the medical baronet.

Rebuilding of the Medical Hospital of the Royal Infirmary of Edinburgh.

The Committee have issued a circular appeal for funds for this object, in which they say, "There are two hospitals in connection with the Royal Infirmary—the Medical and the Surgical. The latter is an excellent one; but the former is not adapted to the requirements of modern times, and is altogether so unsuitable for a public hospital, that it is necessary to have it rebuilt. In particular, it may be mentioned that the wards are much too confined; that the ceilings, which ought to be at least 15 feet high, are only 11 feet; and that the proximity of the buildings in front of the University renders it impossible to secure the free air and ventilation which are desirable. Besides, the hospital, notwithstanding a large annual outlay for *repairs*, is in many respects falling into decay. The total estimated cost is £100,000. Of that sum upwards of £58,000 has already been subscribed.

The Lahore Medical School.

The Lahore Medical School completed its eighth anniversary on the 15th of April, and the report of its satisfactory condition, as an institution for the education of natives in medicine, will be read with interest. It was founded by Sir Robert Montgomery in 1860, and has educated two classes of students—the higher grade educated in English and the lower in Hindustani. There are 25 students in the former, and 75 in the latter class. Most of the students receive scholarships and stipends from government, but within the last few years a certain number of the lower class has consisted of students paid by local funds from different districts, and bound to return to their native places to practice.

The importance of a supply of indigenous medical men is becoming daily greater, now that sanitary science is occupying so much attention in the Punjab and in all other civilized countries; for it is to these men, to men educated at this institution, that we must mainly look to carry out those sanitary regulations by which we hope eventually to prolong human life, to an extent to which it has never yet been done by all our improvements in the treatment of disease. It is therefore satisfactory to find that, as the importance of the medical school increases, its popularity certainly does not diminish.

One very important step has been taken during the last few months; after years of the most urgent representation to Government, and the most vexatious delays and disappointments, the foundation of a commodious hospital has at last been laid in Lahore.

Representation of the Medical Practitioner on the Medical Council.

We understand that this question is likely to come forcibly under the notice of the Medical Council at its approaching meeting, and the debate on it, bearing directly on the interests of the Council, the Licensing Corporations, and the profession at large, cannot but be exciting. The rapid progress which this question has made in public opinion, and the existence of the Medico-Political Association, which has adopted it as its special object, are almost entirely due to the exertions of the *Medical Mirror* pursued energetically against much apathy and opposition. We believe that both Sir Dominic Corrigan and Dr. Andrew Wood may probably bring the matter before the Council, but each has in view a different course to be pursued. Sir Dominic Corrigan entertains the opinion that the representatives of the practitioner should take the places on the Council of the Crown nominees, all of whom, with the exception of Dr. Rumsey, are personally interested in the support of some medical corporation, and cannot be expected, as they were intended, to adjust by an unbiassed vote the balance of contending interests in the Council. In fact, their function in the Council is to dilute the corporation interests, and we think it not disrespectful to these gentlemen to say that their close connection with corporations, and their ingrained prejudices in one or other direction, makes it impossible for them to fulfil their *rôle*. The Medico-Political Association, however, seeing the great difficulty of effecting this interchange of elected for nominated representatives, would seek to add a number of new members to those now in office, but the profession has acquired already a sad experience of the Council deliberations, and cannot see that redundant loquacity and scanty performances will be amended by increasing the number of talkers. Without doubt the principle of direct elective representation of the profession has obtained a hold on the professional mind, but we fear that its realisation, either by

the means proposed by Sir Dominic Corrigan or the Association, is far away.

The Representation of the University of Dublin in the Medical Council.

THE rumours which we noticed some months since, to the effect that the present representative of the University would retire from that position, and would be replaced by the Rev. Professor Haughton, Medical Registrar to the Medical School, have not been realised, although the anticipations had sufficient foundation. Professor Apjohn still occupies the position of representative, which his conduct in the Council deliberations proves that he so eminently merits.

The Dublin City Prisons.

THE right of appointment to the office of Physician to the City of Dublin Prisons has been decisively declared by the Court of Queen's Bench, last week, and the pretension of the Corporation to the patronage reversed by a most explicit judgment. In a former notice of the matter (MEDICAL PRESS AND CIRCULAR, November 6, 1867), we gave the following history of the election, which we reprint, as the facts may probably have passed out of the recollection of our readers :—

"The Corporation of the City of Dublin, in dealing with the medical patronage within their functions, perpetuated, last week, the system of mal-administration and jobbery which has made their name scandalous even in the rank of civic governing bodies. It will be remembered that by the death of the late Dr. Banon, the duty of appointing temporarily to the Surgeoncy of the City of Dublin Prisons became theirs. The election of an officer in permanence to this post, has been always the function of the grand jury, which is a body of decidedly Conservative leanings, and it is provided that in case of a vacancy the corporation, whose ultra-liberal tendencies are well-known, shall appoint a temporary Medical Officer pending the meeting of the grand jury. On the death of the late Dr. Banon, a gentleman was elected who was perfectly eligible in every respect, and none the less so because he was closely allied to one of the members of the Town Council. On the approach of the meeting of the grand jury, it transpired that that body was not likely, from its different political tendencies, to accept the gentleman selected, whereupon a special meeting of the Corporation was held last week at eleven o'clock in the forenoon of the same day, when the grand jury was to meet at two, and the section of the corporation assembled, in spite of the remonstrance of some members, reappointed the same gentleman. At a later hour the grand jury elected to the same office Dr. Byrne, who, we believe, is compelled by this manœuvre to proceed by means of a *quo warranto* to establish the right of appointment to the grand jury. Meanwhile the corporation candidate remains in office, and the funds of the city are squandered in useless and vexatious litigation."

We rejoice in the discomfiture of the Corporation, not in any respect on account of the individual who may occupy the office, but because the defeat of a job is always a public advantage.

We learn from the public papers that the Town Council were before and since strongly advised by their law mentors that they had not the shadow of a claim to the power of appointment, and their determination nevertheless to proceed, at the public expense, to the perpetration of an indecent family job, makes it a matter of congratulation that the attempt should be defeated as it has been.

Vegetarianism.

THE anti-flesh-eating brotherhood have always made it a strong point in favour of their theories that the vegetable-eating inhabitants of India who, as a matter of religious scruple never touch meat enjoy very excellent health and strength, and therefore, this class of diet must be declared to be capable of supporting life and its functions in the highest perfection. Unfortunately for this argument, it appears from recent statistical returns of the officers of health for Bombay, that the persons who restrict themselves entirely to vegetable diet suffer from a much greater mortality than their omnivorous fellows. There are 816,562 inhabitants in Bombay, of whom 61,994 do not eat meat, and, as a rule, this class are of a comparatively high rank in their own society, and enjoy greater opportunities for careful and even luxurious living than the flesh-eating castes. Nevertheless their mortality reaches the proportion of 2·05 per cent., while the general death-rate of the whole population is only 1·89 per cent.

Oxygenation of the Blood.

THE influence which the oxygenation of the blood exercises on the vital functions has recently been demonstrated in a very extraordinary manner by Mr. Claude Bernard. He injected the arteries of the neck with oxygenised blood, immediately after decapitation, with the view of ascertaining how far the phenomena of death were dependant on the withdrawal of the supply.

He found that warmth and muscular sensibility returned, and even that perception returned to the eye, which moved when the hand was passed before it.

New Procedures in Ovariotomy.

WE are informed, on the authority of Dr. Gavin, of the Boston Hospital, U.S., than an operation at which he assisted, was lately performed there, in which two new procedures were adopted, which would seem to be deserving of the attention of operators. In order to allow of the immediate closure of the abdominal wound, and yet to permit of the subsequent removal of the ligatures of the pedicle, they were passed through the uterus and vagina, so that they were readily come at afterwards. With the object, also, of avoiding the exosmosis, which may occur after the washing of the peritoneal cavity with plain water and the exudation of heavier fluids through the intestinal coats, the water was replaced by serum taken from the calf. We have not learned any particulars as to the success of this treatment.

Cool and Healthy Rooms.

PROFESSOR ATTFIELD, in a letter to the *Times* of the 19th inst., on this subject writes :—"In these hot days a cool apartment is a great luxury—the secret consists not in letting in cool air, but in keeping out *hot* air, and recommends that windows should be closed on the sunny side of the house, and when the external atmosphere is hotter than that in the room.

"If the atmosphere of the room be impure, let it be renewed—hot air is less injurious than bad air, but, as a rule, rooms should be kept closed as much as possible until after sundown, or till the air outside is cooler than that inside."

Nitrous Oxide.

THE new anæsthetic is making its way rapidly in the estimation of the profession, and is likely, in spite of the well-grounded physiological objections to its use, to supplant chloroform in dental surgery, and in operations requiring only a brief insensibility to pain.

The agent is undoubtedly a simple suffocant, and if pushed beyond a certain point would cause death, but its advocates insist that nothing but gross negligence would admit of its over administration, and point to the overwhelming (if accurate) statement, that more than 27,000 persons have taken it in America without a fatal result. In the American hospitals in which it is used, it is prepared on the large scale and stored in gas-holders, and as it is not absorbed by water it may be kept an indefinite time; it is admitted by a gas-pipe, and administered to the patient by a large mouth-piece, with separate ingress and egress tubes. A piece of soft wood is placed between the back-teeth to keep the mouth from closing. About five gallons of the gas is necessary to cause anæsthesia and as, in the extensive practice of an hospital, the amount used would necessarily be very large, and the nitrate of ammonia from which it is prepared costs 2s. per lb., an apparatus has been arranged by which the expired gas is passed over hydrate of lime to remove the water and carbonic acid, and it may then be used over again. In the London hospitals a large bag is temporarily used to contain the supply, and one of the administrators has devised a sort of garment resembling a college-gown, which, being inflated with the gas, makes the supply more easily applicable. The patient sits in the operating chair, and takes the mouth-piece between his teeth. He is directed to inspire, and in a few instants the inspirations become more rapid, total insensibility, slight lividity of the face, stertorous breathing, and sometimes throat rattles appear. At that instant the mouth-piece is plucked out and the operation proceeded with. If prolonged anæsthesia be required, the patient must be allowed to recover, and again immediately anæsthetised, and thus insensibility has been kept up for twenty minutes while amputation of the thigh was performed. If air be admitted with the gas, the anæsthesia is not developed, but hilarity and talkativeness, the well-known phenomena of "laughing-gas," are produced, while on the other hand if the administration were not stopped at the proper moment death from asphyxia would undoubtedly ensue. The after-results are in most cases absolutely *nil*. In a minute and a-half, or less, the patient stands up and walks out of the operating theatre as well as ever he was in his life.

It certainly requires moral courage in a surgeon to take the responsibility of suffocating patients into a fit condition for the knife, nevertheless, the practice may now be accepted as an established one, and with the painful experiences of chloroform which we have had, we cannot truly say, even in our present state of knowledge, that a greater risk is incurred by the administrator of the new agent.

There is a renewal of the movement to affiliate licentiates of the London Apothecaries' Society with the College of Physicians. Many would like to be admitted to the College license *ad eundem*. This might be liberal of the Fellows, but then where would the members be. A very much more extended promotion to the Fellowship could alone do justice to the members.

Dr. W. A. Miller has received the honorary degree of LL.D. from the University of Oxford.

The distribution of prizes at Westminster Hospital, took place May 28.

The election of a Chancellor to the University of Edinburgh excites great interest. The names of many Liberals are seen in the list of supporters of the Lord-Justice General, indicating either preference for a local candidate, or a curious indifference to the leader of the Liberal party. Mr. Gladstone's supporters are active, and some Conservatives will vote for him.

Mr. Holmes has resigned the surgeoncy to the Children's Hospital. Mr. Thomas Smith succeeds him.

The Queen has become a subscriber of £100 a-year to the Hants County Hospital, and commanded it to have the prefix "Royal" to its name.

Correspondence.

THE CARMICHAEL PRIZES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having vainly competed upon a former occasion, I naturally feel interested in the essays to which these prizes have been awarded as being superior to any of the others submitted for adjudication. As regards the first essay, to say nothing of the disqualification and bad taste of a member of the body to whom the adjudication was left competing—which was doubtless known to all his colleagues—but taking the essay upon its own merits, I greatly doubt whether the general opinion of those among the profession who may read it will justify the award of the judges.

It is well-known that for many years past much of my attention has been directed to the subject of foreign and English medical organisation, and my chief object in competing was the expectation that should my essay be approved of, and published under the sanction of an influential medical body, it would receive more attention and be likely to be more serviceable than if emanating from myself individually. There was no definite programme or special conditions imposed upon the writers of the essays, though certain suggestions were made by the testator as to the topics to which their attention ought to be more especially directed. My essay (occupying about 400 folio pages of manuscript) entered fully into the consideration of the various parts of the question, more than fulfilling the requirements specified, and though it was very favourably spoken of in the report made by the adjudicators upon the respective essays, it was stated not to have fulfilled all the conditions of the programme.

On subsequently visiting Dublin I learnt that it had been proposed to Sir (then Mr.) J. R. Wilde to compete for the prize, and that he had declined so doing; and thinking that the award was only likely to be made in favour of a competitor in some way connected with the Dublin institutions or of one who would write in their interest—in short, that the affair would be a mere job—I withdrew my essay, declining to compete on any subsequent occasion should such present itself.

As however, during some years, nothing further was done in the matter, and there appeared little probability of any *bona fide* competition I wrote to the President of the Dublin College of Surgeons to remind the council that competitors had been induced to take the trouble of composing their essays in the just expectation that the prizes would be impartially awarded as directed; stating at the same time that parts of my essay had been published at my own cost, and had been favourably reviewed in medical and other journals in England, America, France, and Germany,* but that I was not disposed to incur further expense by publishing the remaining portions, treating of medical studies, hospital elections, examinations for diplomas, private practice, irregular practice, and quackery, &c.; and that I had reason to believe the real cause of the rejection of my essay to be that among the propositions I made for improving the state of the profession was that of substituting for the numerous existing licensing bodies three central examining boards in London, Edinburgh, and Dublin (which proposition as tending to deprive the Dublin College as well as the other corporations of the licensing power was not likely to be ap-

* The Medical Profession in Great Britain and Ireland: Part 1. Foreign Medical Organisation; Part 2. British Medical Organisation. Churchill (now out of print).

proved of by the partial judges forming part of the council of the college),* and I submitted to the council, as no further steps had been taken with regard to the bequest, whether some compensation from that fund ought not to be made to those competitors whose essays had been favourably reported of by the adjudicators, and who had made their best efforts to respond to the wishes of the testator in improving the state of the profession. To this letter I received an answer to the effect that the council were not empowered to comply with my suggestion. I entertain no doubt that an impartial appreciation of the approved essays will show that great injustice has been perpetrated in the award of these prizes, and that they are in nowise calculated to conduce to the improvement of the profession or to promote the accomplishment of the earnest desire of the testator to "render it a more respectable and efficient body."
—Your obedient servant,

June 13, 1868. EDWIN LEE.

ATTEMPTED INTERFERENCE WITH FREEDOM OF EDUCATION IN FRANCE.

THE Senate on the 23rd of May, by a great majority in two successive votes, adopted the order of the day upon the petition relative to accusations directed against materialism in the Paris school and the demand upon the freedom of higher class education.

This result, which was foreseen, had been brought about by a long and brilliant discussion which, we greatly regret, our limited space does not permit us to quote at length, nor fully summarise.

The general secretary of l'Association Générale des Médecins de France has had the honour to see a passage of his eulogy of M. Rayer quoted in this discussion.

The Parisian faculty is freed from a great anxiety: has suffered no censure from the Senate, nor has it to fear, for the present at least, the surrender of free education.

The episcopal thunders have passed harmlessly over its head and, what is still more important, the freedom of science still exists.

The *L'Union Medicale* rejoices greatly at this result. Tolerance for all opinions, liberty for all researches, respect for all doctrines, these are the principles it has always defended, and of which the triumph is henceforth assured.

Free from serious pre-occupations, the limits being determined that teaching can attain to and should not overstep, the faculty can quietly hear and discuss the objections of another order than those which were brought before the Senate ("les objections d'un autor ordre que celni qui a été porté au Sénat"), and which may be directed against its teachings. The right of examining and criticising we do not give up or diminish, and this we shall show when need be.

As to purely medical doctrines the only position we should at present occupy, there exists such diversity and so great a departure from the traditional principles of medicine, that we may here advert to the recent exhibition of the opinions held by some professors of the school of Paris ("Explosion nouvelle de ces opinions professérs par quelques professeurs de l'Ecole de Paris"), and we think that this inquiry will not be unattended with benefit.—*L'Union Medicale.*

Medical News.

THE PUBLIC HEALTH.—It appears from the return made by the Registrar-General that in the week that ended on Saturday, June 13, 5093 births, and 2709 deaths were registered in London and in thirteen other large towns of the United Kingdom. The annual rate of mortality was 22 per 1000 persons living. In London the births of 1175 boys and 1098 girls, in all 2273 children, were registered in the week. In the corresponding weeks of ten years (1858-67) the average number, corrected for increase of population, is 2038. The deaths registered in London during the week were 1195. It was the twenty-fourth week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1263. The deaths in the present return are less by 73 than the estimated number. The deaths from zymotic diseases were 287, the corrected average number being 318. Ten deaths from small-pox, 60 from measles, 22 from scarlatina, 8 from diphtheria, 70 from whooping-cough, 40 from fever, 31 from diarrhœa, and 3 from choleraic diarrhœa were registered. The deaths of 3 persons from delirium tremens, of 7 infants from syphilis, of 4 children from burns or scalds, of 8 persons from drowning, of 5 infants from suffocation, of 2 persons who committed suicide, and of 2 children who were killed by horses or carriages in the streets, were registered.

ST. PANCRAS.—Dr. Hillier, medical-officer of health for the parish of St. Pancras, has presented his annual report to the Vestry, in which he congratulated them on a much lower death-rate having prevailed in the parish during the past year than for several years past. The death-rate in the parish during the last year was 2·154 per cent., while in the whole of London it was 2·298 per cent., and in the northern districts, of which St. Pancras was one, it was 2·319. The mortality of the parish was, therefore, lower than that of the rest of London, or of that part of London in which St. Pancras is situated. He further states:—"I cannot help thinking that the sanitary work done in the houses of the poor during the cholera epidemic of 1866, and the attention paid to the sewers as regards flushing and deodorizing both in 1866 and 1867 have had some considerable influence in keeping down the death-rate. I believe, also, that good has been done by the demolition of some of the more crowded streets in Somerstown, Agar-town, and near the Old St. Pancras-road by the Midland Railway Company. Although very serious inconveniences have been suffered by the poor who were ejected, the houses into which they have removed, though many of them are ill-adapted to receive them, yet have for the most part the advantage of being built further apart so as to allow of free access of air both behind and before."

THE PRINCIPALSHIP OF EDINBURGH UNIVERSITY.—At a meeting held by the Curators of the University of Edinburgh it was resolved to postpone the election of a Principal until the 6th of July.

EDINBURGH UNIVERSITY.—The Rev. Dr. Calderwood, of the United Presbyterian Church of Glasgow, has been elected to the Chair of Moral Philosophy. The election of Principal has been postponed until the 6th of July.

THE UNIVERSITY OF GLASGOW.—We regret to announce the death of Dr. G. W. Arnott, Professor of Botany in this University, after a tedious illness.

UNIVERSITIES OF IRELAND.—A Parliamentary paper recently published shows that of the numbers of persons qualified to form a Parliamentary constituency in Irish Universities 904 persons connected with the Queen's University, and 7715 with the University of Dublin, would be qualified to register. These numbers are calculated upon the supposition that the franchise is to be founded upon all degrees, including in the Queen's University the degrees of B.A. and M.D, as well as diplomas in engineering, and in the University of Dublin all degrees upwards from the B.A. degree.

THE CHAIR OF MIDWIFERY AT GLASGOW.—As in the case of the two other candidates for the Chair of Midwifery at Glasgow, a testimonial, signed by his former pupils, in favour of his appointment to the vacancy, has been presented to Dr. Simpson.

There are at present in the Carmarthen Workhouse ten old people aged respectively 95, 88, 88, 84, 82, 81, 81, 80, 74, and 74 years.

* This proposition was made and warmly advocated by Mr Carmichael in a speech which he delivered on the occasion of his presiding over the annual meeting of the Medical Association for Ireland. Adverting to Mr. Warburton's bill, then before Parliament, he observed, "If it does not lay the axe to the root of the evil, and deprive the several corporations of their licensing power, they may as well allow the present system of misrule to continue unmolested."
